Mm

M is the 13th letter of our alphabet. It was also the 13th letter in the alphabet used by the Semites, who once lived in Syria and Palestine. They named it *mem,* their word for *water,* and adapted an Egyptian *hieroglyphic* (picture symbol) for water. The Greeks called it *mu.* See Alphabet.

Uses. *M* or *m* ranks as the 14th most frequently used letter in books, newspapers, and other printed material in English. It stands for *mile* or *meter* in measurements of distance. In chemistry, *m* is the short form for *metal.* *M* in the Roman numeral system stands for 1,000, while $\overline{M}$ stands for 1,000,000. *M* is also the abbreviation for *Master* in college degrees, and *m* stands for *milli,* as in *millimeter.* In Germany, people use *M* to stand for the *mark,* the basic unit of their money. In French, *M* stands for *monsieur,* equal to our *mister.* It is the seventh letter of the Hawaiian alphabet.

Pronunciation. In English, a person pronounces *m* by closing both lips and making the sound through the nose. Double *m* usually has the same sound, as in *stammer.* But there are some words, like *immobile,* in which each *m* is often pronounced. These words come from a Latin prefix ending in *m* and a Latin stem beginning with *m.* The letter has almost exactly the same sound in French, German, Italian, and Spanish as it has in English. The Romans also gave it the same sound. The Portuguese nasalize the sound when it follows a vowel. See Pronunciation. Marianne Cooley

Development of the letter m

The ancient Egyptians, about 3000 B.C., drew this symbol of waves of water.

The Semites adapted the Egyptian symbol about 1500 B.C. They named the letter *mem,* which was their word for *water.*

The Phoenicians changed the Semitic letter about 1000 B.C.

The Greeks added the letter *mu* to their alphabet about 600 B.C.

The Romans, about A.D. 114, gave the M its capital shape.

The small letter m appeared during the A.D. 300's as a rounded letter. By about 1500, it had developed its present shape.

A.D. 300 — 1500 — Today

Special ways of expressing the letter m

International Morse Code

Braille

International Flag Code

Semaphore Code

Sign Language Alphabet

Common forms of the letter m

Handwritten letters vary from person to person. *Manuscript* (printed) letters, *left,* have simple curves and straight lines. Cursive letters, *right,* have flowing lines.

Roman letters have small finishing strokes called *serifs* that extend from the main strokes. The type face shown above is Baskerville. The italic form appears at the right.

Sans-serif letters are also called *gothic letters.* They have no serifs. The type face shown above is called Futura. The italic form of Futura appears at the right.

Computer letters have special shapes. Computers can "read" these letters either optically or by means of the magnetic ink with which the letters may be printed.

Ma, Yo-Yo (1955-   ), is one of the world's greatest and most popular cello players. Ma has been an international star on his instrument since he was a teen-ager. He has won praise for the warmth and sensitivity of his performances. Ma performs equally well playing solo cello, as part of chamber groups, and as a soloist with orchestras. He plays a broad repertoire that includes music from the 1600's as well as the works of modern composers. In his live performances and recordings, he has united the Western classical music tradition with the music of non-Western cultures.

Ma was born in Paris to Chinese-born parents on Oct. 5, 1955. He moved to the United States with his family at age 7. He studied with the famous cellist Leonard Rose from 1964 to 1971. Ma gained his first major exposure at age 15 when conductor Leonard Bernstein presented him on a television program. After studying at Harvard University from 1972 to 1976, Ma began his career as a soloist. Since then, he has appeared with the world's major symphony orchestras and played chamber music with many distinguished musicians. Stephen Clapp

Ma Yuan, *MAH yoo ehn,* was the most famous member of an honored family of painters. With his fellow painter Xia Gui (also spelled Hsia Kuei), Ma Yuan produced some of the greatest landscape paintings in ink during the early 1200's in the Southern Song (Sung) period in China. Ma Yuan's typical compositions are severely simple, with a framework of strong diagonal lines usually developed in one corner. His foregrounds may contain a few boldly silhouetted forms—rocks, a mountain path, a dramatically angular pine tree. The rest of the scene is largely mist, through which riverbanks or silhouetted faraway peaks can be seen.

Ma Yuan was born in Hezhong in Shanxi province. His birth and death dates are unknown. Robert A. Rorex

Maas River. See Meuse River.

Maasai, *mah SY,* are an African people famous for their skill as warriors and their strongly independent ways. The group's name is sometimes spelled *Masai.* About 250,000 Maasai live in southern Kenya and northern Tanzania.

Traditionally, the ownership of cattle was central to the economy of the Maasai. Their most important foods were milk and the blood of cattle.

Politically, the Maasai were organized into tribal groups led by older men called *fire-stick elders.* Related families lived in small homesteads called *Bomas.* When Maasai boys reached their late teens, they were called *moran.* Moran lived together in separate homesteads called *Manyattas.* They had to prove themselves to be brave warriors by raiding cattle from other Maasai groups or by killing lions. As a Maasai man grew older, he hoped to marry as many women as he could afford. Before marriage, a man offered a gift of cattle to the parents of his future wife.

For many years, the Maasai resisted joining their neighbors' money-based economies. Today, many Maasai have abandoned their traditional ways. They have settled on farms to grow crops for sale or have migrated to urban centers to seek education or employment. Some of the men use their warrior training as security guards in cities, especially in Nairobi, Kenya. John W. Burton

Maazel, *muh ZEHL,* **Lorin,** *LAWR ihn* (1930-   ), has conducted several major orchestras throughout the world. He became music director of the New York Philharmonic in 2002. Maazel served as music director of the Pittsburgh Symphony Orchestra from 1988 to 1996 and conductor of the Bavarian Radio Symphony Orchestra from 1993 to 2002.

Maazel was born on March 6, 1930, to American parents in Neuilly, France, near Paris. He was a child prodigy, conducting several major American orchestras by the age of 15. He joined the Pittsburgh Symphony Orchestra as a violinist in 1948. In 1960, Maazel became the first American to conduct at the famous Bayreuth Festival in Germany. From 1971 to 1982, Maazel was music director of the Cleveland Orchestra. In 1982, Maazel became the first American to head the Vienna State Opera. He held that position until 1984. John H. Baron

Mac, Mc. Biographies of persons whose names begin with *Mac,* such as *MacDonald,* are listed alphabetically under *Mac.* Names that begin with *Mc,* such as *McKinley,* are listed alphabetically under *Mc,* following all names beginning with *Ma* and *Mb.*

Macadamia nut, *MAK uh DAY mee uh,* is a large, round edible seed that grows on two species of trees. Macadamia trees are evergreens native to tropical Australia. The "smooth-shell" macadamia tree, the only commercially important species, grows more than 40 feet (12 meters) tall and bears creamy-white flowers. It was brought to Hawaii in the 1800's. Today, the nuts are an important crop there. Macadamia nuts have a hard, smooth shell. The nuts are cracked, and the white kernels are then dried, roasted in oil, and salted. The roasted nuts are often used in cakes, candy, and ice cream. The nuts are also called *Australian nuts, bopple nuts, bush nuts,* and *Queensland nuts.* Michael J. Tanabe

Scientific classification. Macadamia trees belong to the protea family, Proteaceae. The scientific name for the smooth-shell macadamia tree is *Macadamia integrifolia.*

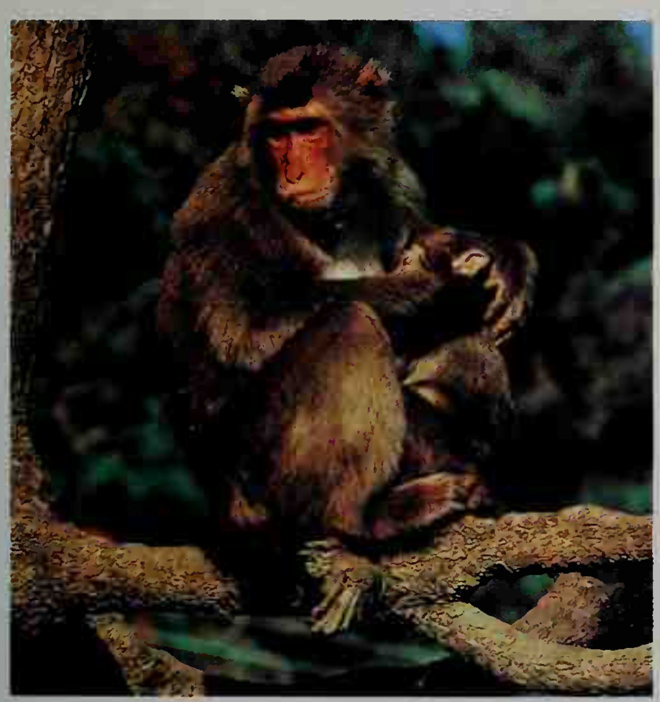
Macao, *muh KOW,* also spelled *Macau* (pop. 436,000), is a special administrative region of China and a former territory of Portugal. It consists of the city of Macao, which occupies a peninsula, and the islands of Taipa and Colôane. The region covers about 8 square miles (21 square kilometers). It lies at the mouth of the Zhu Jiang (Pearl River), about 40 miles (64 kilometers) west of Hong Kong (see Asia [political map]).

Some parts of Macao feature architecture from the colonial era. These areas have old churches and pastel-colored houses lining cobblestone streets. Other parts of Macao have modern high-rise apartments, hotels, and office buildings. More than 95 percent of the people are Chinese. A small fraction of the population is of Portuguese ancestry. Macao's economy is based on tourism and light industry. Leading industries include the manufacture of fireworks, furniture, textiles, and toys. Gambling casinos in Macao attract many tourists.

Portugal established a permanent settlement in Macao in 1557. Initially, Portugal paid China an annual rent for the land. But in the 1840's, Portugal stopped paying rent and evicted the remaining Chinese authorities. China recognized Portuguese control in 1887. In 1966, pro-Communist Chinese living in Macao rioted against the Portuguese administration of the territory.

Portugal returned Macao to China in December 1999 under an agreement signed by both countries in 1987. As a special administrative region of China, Macao

maintains separate political, judicial, and social systems from the rest of the country. China, however, appoints the chief executive of Macao. Jonathan Porter



Macaque, *muh KAK* or *muh KAHK,* is the name of a group of large, powerful monkeys. Some weigh over 30 pounds (14 kilograms). Macaques have a wider geographical range than any other monkey or ape. Most species live in warm areas of southern Asia. One species, the *Barbary ape,* lives in northern Africa (see **Barbary ape**). Another, the *Japanese macaque,* lives as far north as Honshu Island, where snow falls in winter.

Most macaques have gray or brown fur, with pink or red skin on the face and rump. Some have long tails, and others have short tails or no tails at all. Males have long, sharp teeth that they use in fighting. Strong males rule most groups of macaques.

Many macaques live both in trees and on the ground. Most species eat fruits, grains, insects, and vegetables, but the *crab-eating macaque* eats crabs and clams.

The *rhesus monkey,* a macaque of India, was once widely used in medical research. India banned the export of rhesus monkeys in 1978 and since then their use in research has declined (see **Rhesus monkey**). People of Malaysia train the *pigtailed macaque* to pick coconuts from trees. Several species of macaques are threatened with extinction. Randall L. Susman

Scientific classification. Macaques make up the genus *Macaca* in the family Cercopithecidae.

© Warren Garst, Tom Stack & Assoc.

The Japanese macaque has brown fur and a short tail. Its reddish face and rump are features common to all macaques. Both male and female macaques protect and care for their young.

MacArthur, Douglas (1880-1964), was a leading American general of World War II and the Korean War. He also won distinction as Allied supreme commander of the occupation of Japan after World War II.

Early career. MacArthur was born in Little Rock, Arkansas, on Jan. 26, 1880. His father, Arthur MacArthur, had been a hero as an officer in the Civil War (1861-1865). The elder MacArthur became a prominent general during the Spanish-American War (1898) and a revolt against U.S. control of the Philippines from 1899 to 1902.

MacArthur graduated from the U.S. Military Academy at West Point, New York, in 1903. He achieved one of the highest academic records in the school's history. During the next 10 years, he served as an aide and junior engineering officer in the Philippines, Panama, and the United States. MacArthur was on the general staff of the War Department for four years. In 1914, he served with the American forces that seized the Mexican city of Veracruz (see **Wilson, Woodrow** [Crisis in Mexico]).

World War I. MacArthur held the rank of major when the United States entered World War I in April 1917. He became chief of staff of the 42nd Division, nicknamed the Rainbow Division, and served in France. MacArthur became known as an outstanding combat leader, especially in the St.-Mihiel and Meuse-Argonne offensives. He was wounded twice and received many decorations for bravery. By June 1918, MacArthur had risen to the rank of brigadier general.

Between world wars. After occupation duty in Germany, MacArthur was superintendent of the U.S. Military Academy from 1919 to 1922. Later in the 1920's, he served in the Philippines and again in the United States.

In 1930, at the age of 50, MacArthur became chief of staff of the U.S. Army. The Great Depression, a worldwide economic slump, hampered his efforts to modernize and expand the Army during his five years in this office. From 1935 to 1941, MacArthur served as military adviser to the Commonwealth of the Philippines. The Philippines, which had been a U.S. possession since 1898, were being prepared for independence.

World War II. In July 1941, President Franklin D. Roosevelt made MacArthur commander of the Army forces in the Far East. On Dec. 7, 1941, Japanese planes bombed the U.S. naval base at Pearl Harbor in Hawaii and attacked American air bases in the Philippines. The United States entered World War II when it declared war on Japan on December 8. A major Japanese invasion of the Philippines began two weeks later.

MacArthur led the defense of the Philippines. He concentrated his Filipino and American troops on Bataan

National Archives

General Douglas MacArthur, *second from left,* returned to the Philippines when he waded ashore at Leyte on Oct. 20, 1944.

Peninsula and Corregidor Island in Manila Bay. In March 1942, under orders from Roosevelt, MacArthur and his family left Corregidor. Soon afterward, MacArthur flew to Australia. Upon his arrival, he made a pledge that became famous: "I shall return." See **Bataan Peninsula.**

MacArthur received the Medal of Honor for his defense of the Philippines. His father had won this medal, the nation's highest military award, for his heroism in the Civil War. The MacArthurs are the only father and son who have both received it.

Roosevelt appointed MacArthur commander of the Allied forces in the Southwest Pacific, and the general began an offensive against Japan. Early in 1943, MacArthur's forces drove the Japanese from southeast New Guinea. His troops then seized northeast New Guinea, western New Britain, and the Admiralty Islands. These victories isolated the Japanese base at Rabaul, the chief port of New Britain. By September 1944, MacArthur had also recaptured western New Guinea and Morotai.

On Oct. 20, 1944, MacArthur and his forces landed on the Philippine island of Leyte, thus carrying out his pledge to return. His troops landed on Mindoro in the central Philippines in December. MacArthur became a five-star general that same month. His troops invaded Luzon in January 1945 and recaptured most of that island by the time the war ended in August. He also retook the southern Philippines and Borneo.

Japan surrendered in August 1945, and MacArthur was appointed Allied supreme commander. He presided over the surrender ceremony aboard the U.S.S. *Missouri* on September 2 and then took over as commander of the Allied occupation forces in Japan.

The occupation of Japan. From 1945 to 1951, MacArthur headed the Allied occupation of Japan. The occupation had the basic goals of demilitarizing Japan and making it a democratic nation. MacArthur administered the occupation with great independence, and he introduced major reforms in Japan's political, economic, and social institutions. The Japanese respected MacArthur's capable leadership. He used the Japanese emperor and government to help carry out the reforms.

The occupation programs removed from power supporters of military conquest and reduced the control that a small group of Japanese families had over the nation's industry. A land reform program enabled farmers to own their own land. Labor unions were recognized, the government improved public health and education, and women received the right to vote. A new Japanese constitution went into effect in 1947. MacArthur also headed the U.S. Far East Command from 1947 to 1951.

The Korean War began on June 25, 1950, when North Korean troops crossed the 38th parallel, the border between North and South Korea. President Harry S. Truman appointed MacArthur head of the military force that the United Nations (UN) sent to defend South Korea. MacArthur led a surprise landing behind enemy lines at the South Korean port of Inchon. This move changed the course of the war, enabling the UN forces to capture Seoul and causing an almost total collapse of the North Korean army. MacArthur then invaded North Korea.

Before MacArthur could win a total victory over North Korea, however, Communist Chinese forces entered the war on the side of the North Koreans. The Chinese drove the UN forces south of the 38th parallel. As a result, MacArthur wanted to extend the war into China. However, some members of the UN feared that attacking China would start a third world war. MacArthur strenuously disagreed with Truman and the Joint Chiefs of Staff about limiting the war to Korea.

By March 1951, MacArthur's forces held positions close to the 38th parallel. MacArthur then issued statements critical of the government's policy and strategy on the war. He was defying Truman's orders not to release policy statements on his own initiative. MacArthur also sent an unauthorized message demanding the surrender of the Chinese. On April 5, Joseph W. Martin, Jr., a Republican congressman, made public a letter from MacArthur that criticized official policy. Because of these disagreements, on April 11, President Truman relieved MacArthur as head of the UN Command, U.S. Far East Command, and occupation of Japan.

MacArthur was welcomed as a hero on his return to the United States. It was his first time back in the country since 1937. After a Senate investigation of his dismissal, popular support for his position declined sharply.

Last years. Some conservative Republicans tried in vain to get their party to nominate MacArthur for the presidency in 1944, 1948, and 1952. In 1952, MacArthur became chairman of the board of Remington Rand, Inc. (now part of Unisys Corporation). His memoirs, *Reminiscences,* were published shortly before he died on April 5, 1964. After a state funeral, he was buried in the MacArthur Memorial in Norfolk, Virginia. D. Clayton James

MacArthur Foundation is a private, independent organization that funds a variety of charitable and public service projects. It ranks as one of the 10 largest foundations in the world. Its official name is the John D. and Catherine T. MacArthur Foundation.

The MacArthur Foundation supports eight main programs. The MacArthur Fellows Program sponsors talented individuals of all skills and ages. The winners receive a large sum of money to pursue their interests in whatever way they choose. The General Program develops special initiatives, which include projects not covered under the foundation's other programs. It also promotes diversity on television and radio.

Six separate programs fund specific research or development. The Community Initiatives Program supports cultural and community development in Palm Beach, Florida, and in Chicago, where the MacArthurs had homes. The Education Program fosters literacy, mathematics skills, and critical and creative thinking. The Health Program sponsors research on mental health and on diseases caused by parasites. The Program on Peace and International Cooperation aids the study and public understanding of international security. The Population Program seeks to solve problems caused by the world's

rapid population growth. The World Environment and Resources Program promotes public education and studies about environmental issues, and conservation.

John D. MacArthur created the foundation in 1970 with his fortune from insurance and real estate. It announced its first grant winners in 1978. Its headquarters are in Chicago. Critically reviewed by the MacArthur Foundation

Macau. See Macao.

Macaulay, Thomas Babington (1800-1859), was the most widely read English historian of the 1800's. He also achieved fame for his essays and for his poems based on legends. However, Macaulay's writings—especially his poetry—declined in popularity during the 1900's.

Macaulay was born in Leicestershire on Oct. 25, 1800. His father, Zachary Macaulay, was a leading religious reformer. In 1825, Macaulay published his first article, an essay on the English poet John Milton, in the famous literary magazine *The Edinburgh Review.* The *Review* continued to publish many of Macaulay's scholarly but popular essays on historical and literary topics.

While Macaulay was gaining a reputation as an author, he was also pursuing a political career. He was elected to Parliament in 1830 and helped lead a movement to reform British voting laws. His speeches in Parliament were so brilliant that he became a famous public figure. In 1833, the English East India Company appointed Macaulay to the Supreme Council, which governed the British colony of India. He served on the council until 1838. From 1834 until 1838, he lived in India and helped lay the foundations for British systems of criminal law and education in the colony.

After Macaulay returned to England, he began his greatest work—*The History of England from the Accession of James II.* He published two volumes in 1849 and two more in 1855. After his death, his sister, Lady Trevelyan, edited the final volume, which was published in 1861. The *History* became a best seller in the United Kingdom and the United States due to its vivid descriptions and powerful prose style. The work contains some factual errors, and scholars have challenged Macaulay's slanted political views. But the *History* remains a highly readable introduction to a period of English history.

While working on his *History,* Macaulay remained a leading orator in Parliament and held several government posts. At the same time, he wrote *Lays of Ancient Rome* (1842), a collection of poems about ancient Roman heroes. Its best-known poem is "Horatius." K. K. Collins

See also **Horatius; Fourth estate.**

Macaw, *muh KAW,* is the name of about 18 *species* (kinds) of large, long-tailed parrots that live in forested areas of South America, Central America, and Mexico. Macaws are the largest parrots. They measure from 12 to 39 inches (30 to 100 centimeters) long. These birds have long pointed wings and a heavy, powerful bill. Beautifully colored feathers of blue, red, yellow, and green cover the body. Macaws nest in holes in tall trees. They eat nuts, seeds, and fruit. They often can be seen flying swiftly in pairs over a tropical rain forest. Macaws can be easily tamed, but do not readily learn to talk. They are not recommended as household pets because they scream loudly and may bite. John W. Fitzpatrick

Scientific classification. Typical macaws are members of the family, Psittacidae. They make up the genus *Ara.*

See also **Parrot** (picture: Scarlet macaw); **Animal** (picture: Animals of the tropical forests).

Macbeth, *muhk BEHTH* (? -1057), seized the throne of Scotland in 1040 after defeating and killing King Duncan I. He based his claim to the crown on his victory and his wife's royal ancestry. Malcolm III, son of Duncan I, and Earl Siward of Northumberland defeated Macbeth at Dunsinane in 1054, but they did not dethrone him. Three years later, Malcolm III killed Macbeth at Lumphanan. Macbeth's stepson Lulach reigned for a few months, and then Malcolm III succeeded Lulach as king.

William Shakespeare based his play *Macbeth* upon a distorted version of these events that he found in Raphael Holinshed's *Chronicles of England, Scotland, and Ireland* (1578). The only historical truth in the play is Duncan's death at the hand of Macbeth. From this fact, Shakespeare drew his portrait of ambition leading to a violent and tragic end. Joel T. Rosenthal

Maccabee, Judah. See Judah Maccabee.

MacCool, Finn. See Finn MacCool.

MacDonald, James Ramsay (1866-1937), led the first Labour Party government of the United Kingdom (U.K.). He served as the first Labour Party prime minister of the U.K. in 1924. He was also prime minister from 1929 to 1935. MacDonald was secretary of the British Labour Party from the party's origin in 1900 until 1912.

MacDonald entered Parliament in 1906. As Labour Party leader in 1914, he opposed England's entry into World War I. His stand met considerable opposition within his own party. His pacifism resulted in his defeat for reelection to Parliament in 1918. But he was elected in 1922 and became prime minister in January 1924. MacDonald remained in office for only 10 months. He was defeated, in part, because his government was considered too friendly toward the Soviet Union. MacDonald accepted, but did not wholeheartedly support, the 1926 general strike on behalf of coal miners faced with reduced wages and longer working hours.

The Labour Party won the general election of 1929, and MacDonald formed his second government as prime minister. It achieved considerable success in international affairs. Diplomatic relations with the Soviet Union were resumed. MacDonald visited the United States to discuss with President Herbert Hoover proposals for naval reduction. He became chairman of the London arms conference in 1930. But MacDonald was unable to deal effectively with rapidly rising unemployment, and his government resigned in August 1931. MacDonald continued as prime minister, heading a national coalition government of Labour, Conservative, and Liberal Party members. A large majority of the Labour members of Parliament disapproved of his move. The Conservatives held an overwhelming majority in the government. They overshadowed MacDonald. Stanley Baldwin replaced him as prime minister in 1935.

MacDonald was born of farmer parents on Oct. 12, 1866, in Lossiemouth, Scotland. At age 20, he went to London and worked as a clerk, accountant, and journalist. He read widely in the fields of science, history, and economics. He became interested in socialism, joined the Fabian Society, and became one of its speakers.

Macdonald, Sir John Alexander (1815-1891), was the first prime minister of the Dominion of Canada. He is often called the father of present-day Canada because he played the leading role in establishing the dominion in 1867. Macdonald served as prime minister from 1867 until 1873 and from 1878 until his death in 1891. He held the office for nearly 19 years, longer than any other Canadian prime minister except W. L. Mackenzie King, who served for 21 years.

Macdonald, a Conservative, entered politics when he was 28 years old. During his long public career, Canada grew from a group of colonies into a self-governing, united dominion extending across North America. Macdonald stood out as the greatest political figure of Canada's early years. He helped strengthen the new nation by promoting western expansion, railway construction, economic development, and harmony between English-speaking and French-speaking Canadians.

A man of great personal charm, Macdonald knew how to make people like him. He was naturally sociable, with a quick wit and a remarkable ability to remember faces. Unlike most politicians of his day, Macdonald kept his speeches short, simple, and filled with funny stories. People preferred his talks to the long, dull, and flowery speeches of others.

Early life

Boyhood and education. John Alexander Macdonald was born on Jan. 11, 1815, in Glasgow, Scotland. He was the son of Helen Shaw Macdonald and Hugh Macdonald, an easygoing and usually unsuccessful businessman. John had an older sister, Margaret, a younger sister, Louisa, and a younger brother, James. James was killed in 1822, at the age of 5, by a babysitter. John was 5 years old when the family moved to Canada in 1820.

The Macdonalds settled in Kingston, Upper Canada (in present-day Ontario). Hugh opened a small shop, and the family lived above it. The business did not prosper. In 1824, the family moved westward to Hay Bay. They moved to Glenora in Prince Edward County in 1825, then back to Kingston. Hugh tried one business after another, but none brought him success.

As a boy, John became interested in books and was a bright student. He finished his formal schooling in 1829 when he was 14. In 1830, John began to study law with George Mackenzie, a prominent Kingston lawyer. He lived with the Mackenzie family and worked in the law office. In 1833, John learned that a relative, a lawyer in Hallowell, Prince Edward County, was seriously ill. John agreed to take over his practice.

Lawyer. Macdonald returned to Kingston in 1835. He was admitted to the bar of Upper Canada in 1836. That same year, he took on his first apprentice-lawyer, Oliver Mowat, who later became premier of Ontario and, with Macdonald, one of Canada's Fathers of Confederation (see **Confederation of Canada**).

In 1838, American supporters of William Lyon Mackenzie, a leading opponent of British rule in Upper Canada, staged a raid into Canada. About 150 raiders were captured, and Macdonald defended some of them in

court. Several Americans were hanged, but the case helped establish Macdonald's legal reputation. See **Rebellions of 1837; Mackenzie, William Lyon.**

In 1841, Upper Canada (part of present-day Ontario) and Lower Canada (part of present-day Quebec) united to form the Province of Canada. The Province of Canada, sometimes called United Canada, had one legislative assembly, with an equal number of members from Upper and Lower Canada.

Kingston, in Upper Canada, became the capital of the Province of Canada. Both the city and Macdonald's law practice grew prosperous. In 1843, Macdonald began a law partnership with Alexander Campbell. Campbell had been Macdonald's second apprentice-lawyer and would become another one of the Fathers of Confederation.

Marriages. On the same day that Macdonald set up his law partnership, he married his cousin Isabella Clark. The Macdonalds had two sons, John Jr., who died at the age of 1, and Hugh John, who became premier of Manitoba. In 1844, Isabella became ill. Macdonald and his wife were separated for long periods while Isabella tried to restore her health in the United States. But she died in 1857. The years of his wife's illness were a strain on John Macdonald, both physically and financially. He remained at Isabella's bedside as much as possible. But he was also building a law practice and a political career. He often felt he was not giving enough attention to his wife, to his practice, or to politics.

In 1867, Macdonald married Susan Agnes Bernard. The couple had a daughter, Mary.

Early public career

In 1843, at the age of 28, Macdonald was elected an alderman in Kingston. In 1844, he accepted the Conservative nomination in Kingston for a seat in the Legislative Assembly of the Province of Canada. He easily won election.

Macdonald's associates in the Assembly soon recognized his political abilities. In 1847, he was appointed receiver general in the Conservative administration of William Henry Draper. But Draper's government was defeated later that year.

For the next few years, Macdonald helped rebuild the Conservative Party. He wanted the party to include men of liberal and conservative views, French-Canadians and English-Canadians, Roman Catholics and Protestants, and rich and poor. A Liberal-Conservative coalition government was formed in 1854 under Conservative leader Sir Allan McNab. Macdonald served as attorney general in this administration.

Associate provincial prime minister. In 1856, Macdonald and Étienne P. Taché became associate prime ministers of the Province of Canada. Taché was the senior prime minister in what was called the Taché-Macdonald government. The next year, Taché retired. Macdonald became senior prime minister with George É. Cartier as his associate prime minister.

In 1858, the Macdonald-Cartier government suffered a defeat in the Assembly, and the two men resigned as prime ministers. But a week later, the governor general, the British monarch's representative in Canada, asked Cartier to become senior prime minister and form a government. With Macdonald's help, the new government became the Cartier-Macdonald government.

Under an Assembly rule, the cabinet ministers in this government normally would have been required to win reelection to their Assembly seats after being appointed to the cabinet. However, the rule did not apply to ministers who resigned and accepted another cabinet position within a month. To take advantage of this rule, the ministers simply returned to office with new titles. Then they quickly dropped the new titles and resumed their former offices. This avoidance of the need to seek reelection became known as the "double shuffle." It was legal, but the opposition charged it was dishonest.

The Conservative government was defeated in 1862, although Macdonald had easily won reelection to the assembly from Kingston in 1861. Macdonald served as leader of the opposition party until 1864. The Conservatives won the election that year. Taché came out of retirement, and the second Taché-Macdonald government was formed.

Forming the Dominion. In the early 1860's, the northern half of North America was called British North America. It consisted of only a few provinces. Most of the people lived in the east. The Maritime Provinces—New Brunswick, Newfoundland, Nova Scotia, and Prince Edward Island—lay along the Atlantic coast. The Province of Canada was next to them on the west. Of these five provinces, Nova Scotia and the Province of Canada were older and more developed. Farther west was an expanse of mainly unsettled territory owned by the Hudson's Bay Company (see **Hudson's Bay Company**). On the west coast lay British Columbia, then a British colony.

For several years, the British provinces in North America had considered the idea of confederation. Several factors gave force to this idea. They included the frequent changes of provincial governments, the desire to expand to the west, and fear of U.S. expansion.

Nova Scotia and the Province of Canada led the confederation movement. In the Province of Canada, Macdonald joined with his opponent, Reform Party leader George Brown, to achieve confederation.

From 1864 to 1867, Macdonald led in planning confederation. In September 1864, he attended a conference in Charlottetown, P.E.I., to present the confederation plan to the Maritime Provinces. In October, delegates from all the provinces gathered at a second conference in Quebec. At this meeting, Macdonald was largely responsible for drawing up the Quebec Resolutions, the plan for confederation.

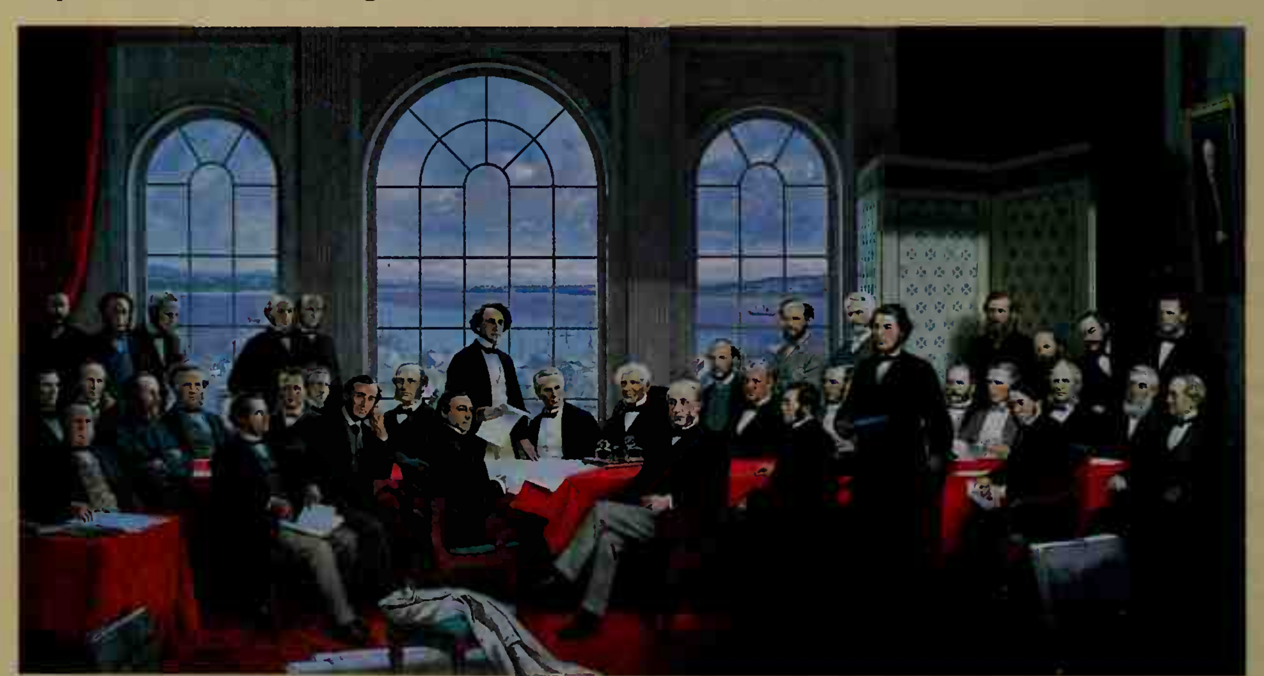
New Brunswick, Nova Scotia, and the Province of Canada approved the idea, but Newfoundland and Prince Edward Island rejected it. Final details were agreed upon at a conference in London in 1866. In 1867, the British Parliament passed the British North America Act, which brought the Dominion of Canada into being (see **British North America Act**). The new nation had four provinces: Ontario (previously Upper Canada), Quebec (previously Lower Canada), New Brunswick, and Nova Scotia. The governor general, Viscount Monck, asked Macdonald to become prime minister.

Confederation was largely Macdonald's achievement and Queen Victoria knighted him for it. The announcement of his knighthood came on July 1, 1867, the first day of the Dominion's existence. A general election, in which Macdonald and the Conservatives triumphed,

was held in August and September, and the new Parliament assembled on Nov. 6, 1867.

First term as prime minister (1867-1873)

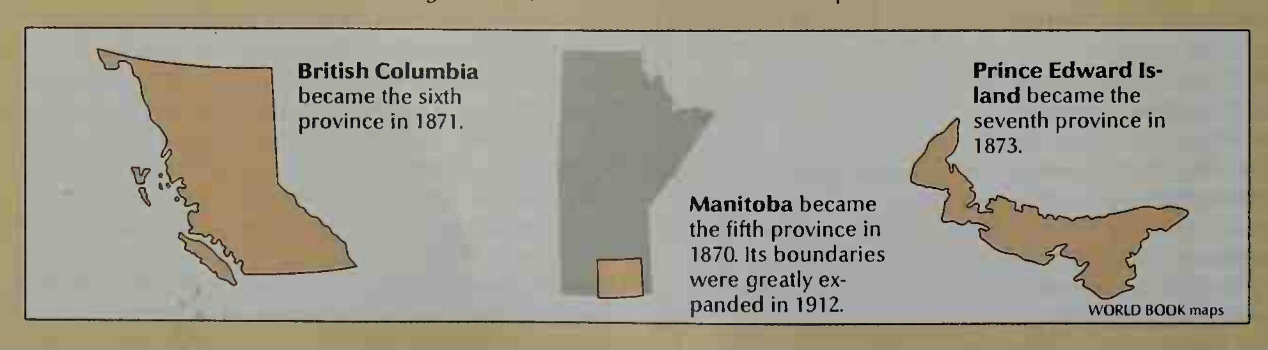
Completing the Dominion. Sir John A. Macdonald took office as prime minister of the Dominion of Canada on July 1, 1867. His goal was to enlarge the Dominion into a unified nation extending across the continent.



In 1869, the Canadian and British governments agreed with the Hudson's Bay Company to purchase the company's lands. The company was paid 300,000 pounds (about $\$1\frac{1}{2}$ million) and 5 percent of the land south of the North Saskatchewan River. But the *métis* (persons of mixed white and Indian descent) in the purchased territory rebelled. They were led by Louis Riel. They feared that an onrush of settlers would deprive them of their lands. Many Canadians also thought the United States might annex this land. Parliament passed the Manitoba Act in 1870, and in July 1870, Manitoba became Canada's fifth province and the first province to be added to the Dominion of Canada (see **Red River Rebellion**). British Columbia became the sixth province in 1871, and Prince Edward Island the seventh in 1873.

In 1871, delegates from Britain and the United States held a conference in Washington, D.C. Macdonald at-

Important dates in Macdonald's life



- **1815** (Jan. 11) Born in Glasgow, Scotland.
- **1820** Macdonald family moved to Kingston, Upper Canada.
- **1836** Admitted to the bar of Upper Canada.
- **1843** (Sept. 1) Married Isabella Clark.
- **1844** (Oct. 14) Elected to Legislative Assembly of the Province of Canada.
- **1856** Became associate prime minister of Province of Canada.
- **1857** (Dec. 28) Mrs. Isabella Macdonald died.
- **1867** British Parliament passed the British North America Act. (Feb. 16) Married Susan Agnes Bernard. (July 1) Macdonald became the first prime minister of the Dominion of Canada and was knighted.
- **1869-1870** Louis Riel led the Red River Rebellion.
- **1870** Manitoba became the fifth Canadian province.
- **1871** British Columbia became the sixth province.
- **1873** Prince Edward Island became the seventh province.
- **1878** (Oct. 17) Became prime minister for second time.
- **1885** Riel led the North West Rebellion. The Canadian Pacific Railway (now CP Rail System) was completed.
- **1891** Macdonald and the Conservatives won reelection. (June 6) Died in Ottawa, Ont.

Important events during Macdonald's Administrations

Fathers of the Confederation (1864), an oil painting on canvas by J. D. Kelly; Confederation Life Collection, Toronto, Canada

The Quebec Conference of 1864 drew up the plan that united the provinces of Canada into the Dominion of Canada. Macdonald, *standing at center,* became the new nation's first prime minister.

tended the meeting as the Canadian member of the British delegation. He tried to obtain a trade agreement with the United States, but was not successful. Nevertheless, Macdonald signed the Treaty of Washington. Among other points, this treaty granted the United States extensive fishing rights in Canadian waters. Macdonald felt that refusal to sign the treaty might encourage the United States to use force to win its demands. He was always careful to do nothing that might endanger the young Canadian nation. See **Washington, Treaty of.**

The Pacific Scandal. Next, Macdonald turned to the issue of building a transcontinental railroad to unify Canada. The completion of such a railroad had been one of the terms of British Columbia's entry into the Confederation.

Two financial groups competed with each other to build the line. Then, in 1873, it was learned that Sir Hugh Allan, head of one of the groups, had contributed a large sum of money to help reelect Macdonald's government in the 1872 election. Some Liberal members of Parliament charged there had been an "understanding" between Allan and the government. They accused the government of giving Allan a charter to build the railroad because he had contributed to the Conservatives' election fund.

The incident became known as the Pacific Scandal. Macdonald claimed that he was innocent, but evidence showed that he and some of his associates had received a large amount of money from Allan. Macdonald resigned as prime minister. He offered to resign as head of the Conservative Party, but his supporters persuaded him to remain in that post. The Conservative Party lost the 1874 election, although Macdonald won reelection to Parliament from Kingston. Alexander Mackenzie, the leader of the Liberal Party, succeeded Macdonald as prime minister.

The National Policy. After the 1874 election, Macdonald led the opposition party in the House of Commons. He began to rebuild the Conservative Party. Macdonald favored a program of economic nationalism that he called the National Policy. This program called for developing Canada by protecting its industries against competing industries of other countries.

The idea appealed to Canadians, especially because a depression had begun in 1873. On the strength of the National Policy, the Conservatives defeated the Liberals

Louis Riel led revolts against the Canadian government in 1869-1870 and in 1885. English-Canadians called him a traitor. But French-Canadians hailed Riel as a hero.

CP Rail System

The Canadian Pacific Railway was completed in British Columbia with the driving in of the last spike in 1885.

in the 1878 election. They returned to power with an election victory in almost every province.

Second term as prime minister (1878-1891)

National prosperity. Macdonald began his second term as prime minister on Oct. 17, 1878. In 1879, the government began putting the National Policy into effect by placing tariffs on a variety of goods. Macdonald again began to push for construction of a transcontinental railroad. With government support, a new company was formed. By November 1885, the Canadian Pacific Railway (now CP Rail System) had been completed to the Pacific Ocean. Macdonald had achieved his program of western expansion, railway construction, and economic nationalism. Canada rode a wave of prosperity.

Threats to Canadian unity. Macdonald had worked long and hard to build a unified Canadian nation. But beginning in 1885, a number of political developments seriously threatened this unity.

In 1885, the métis of northwest Canada rebelled for the second time. They were again led by Louis Riel. When Riel finally surrendered, he was found guilty of treason and sentenced to hang. The sentence caused severe bad feeling between French-Canadians and English-Canadians. For a time, the issue threatened to split the confederation. However, Macdonald refused to give in to Riel's supporters. "He shall die though every dog in Quebec bark in his favour," Macdonald declared. Riel was hanged in November, 1885. See **North West Rebellion.**

Macdonald next faced an attack by the provincial premiers against his program for a strong central government. In 1887, five of the premiers met at a conference in Quebec. They proposed changes in the British North America Act that would decentralize the Canadian government. Neither the Canadian government nor British authorities seriously considered the premiers' demands. However, the conference showed the growing strength of provincial opinion against federal centralization.

Still another blow to Macdonald was the depression of 1883. The National Policy had not produced all the expected results. In 1886 and 1887, a demand arose for a change in Canada's financial policy. Some people favored political federation with Britain. Others spoke of a commercial union with the United States. Macdonald opposed both proposals.

In the 1891 election, the Liberals adopted a party platform calling for unrestricted reciprocal trade with the United States (see **Reciprocal trade agreement**). The 76-year-old Macdonald fought this proposal with all the strength he could muster.

"Shall we endanger our possession of the great heritage bequeathed to us by our fathers," he asked the Canadian people, "and submit ourselves to direct taxation for the privilege of having our tariffs fixed at Washington, with the prospect of ultimately becoming a portion of the American Union? . . . As for myself, my course is clear. A British subject I was born, a British subject I will die." With this appeal, Macdonald won his last election.

Death. The strain of campaigning proved severe for Macdonald. He became ill after a long day of speaking, and suffered a stroke on May 29, 1891. He died on June 6 in Ottawa. Macdonald was buried near his mother in Kingston, Ontario. Donald Swainson

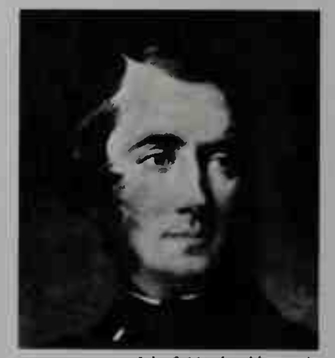
MacDonald, John D. (1916-1986), was an American mystery writer best known for his 21 novels featuring Travis McGee, an amateur detective. He wrote more than 65 novels and over 500 short stories.



The first McGee novel was *The Deep Blue Good-By* (1964). McGee lives off the coast of Florida on a houseboat called *The Busted Flush.* He calls himself a "salvage consultant," but his real business is rescuing people from various kinds of trouble and recovering lost or stolen money. McGee is tough and cynical, but also sensitive and moral, and has a strong sense of honor. MacDonald used the character of McGee to expose the corruption that the author saw in modern American life. Typical McGee novels include *The Dreadful Lemon Sky* (1975) and *Free Fall in Crimson* (1981).

MacDonald's other works also show his skill as a mystery writer. Among his suspenseful thrillers are *The Executioners* (1958), *The Last One Left* (1967), and *Condominium* (1977). John Dann MacDonald was born in Sharon, Pennsylvania. David Geherin

Macdonald, John Sandfield (1812-1872), served as joint prime minister of the Province of Canada from 1862 to 1864. The province was in what are now southern Ontario and southern Quebec. Macdonald was joint prime minister with Louis-Victor Sicotte from 1862 to 1863 and with Antoine-Aimé Dorion from 1863 to 1864. He also served as the first premier of Ontario from 1867 to 1871.

Macdonald belonged to the Reform Party, which eventually became the Liberal Party. In the early 1850's, he became a leader of the radical wing of the Reform Party in Upper Canada, the western part of the Province of Canada. But in 1856, control of the wing shifted to his political rival George Brown (see **Brown, George**).

Macdonald differed with Brown on several key issues. For example, Macdonald opposed the principle of *representation by population*—that is, basing the number of an area's elected representatives on the area's population. He felt this practice would weaken the rights of the French-speaking population in Lower Canada, the eastern part of the Province of Canada. Most of the province's people lived in Upper Canada and spoke English. Macdonald supported a *double majority system,* under which gov-

John S. Macdonald, portrait by Samuel B. Waugh, Public Archives of Canada, Toronto

John S. Macdonald

ernment proposals could be vetoed either by the representatives of Upper Canada or by those of Lower Canada. He also opposed Brown's goal of uniting the Canadian colonies under a central government. Macdonald was born in what is now St. Raphaels, Ontario, near Alexandria. J. M. Bumsted

Macdonald, Ross (1915-1983), was the pen name of Kenneth Millar, an American writer of detective novels. Macdonald's best-known books feature Lew Archer, a private detective. The Archer novels are "hard-boiled" detective fiction, which emphasizes realism and violence. But Macdonald also explored the psychological and social forces that lead to crime. His works are also noted for their highly literate prose style.

Much of Macdonald's work features the theme of a family broken by the loss of the father. Many of his characters seek close personal relationships and the meaning of life in a world that seems impersonal. The action takes place amid southern California's landscapes and changing lifestyles, which he portrayed vividly. Macdonald introduced Archer in *The Moving Target* (1949). Archer appeared in 17 other novels, including *The Chill* (1964), *The Far Side of the Dollar* (1965), *The Goodbye Look* (1969), *The Underground Man* (1971), and *The Blue Hammer* (1976). Macdonald's short stories were collected in *Lew Archer, Private Investigator* (1977).

Macdonald was born in Los Gatos, California, and grew up in Canada. His Canadian-born wife, Margaret Millar, also wrote detective novels. David Geherin

Macdonough, *muhk DAHN uh,* **Thomas** (1783-1825), an American naval officer, became a hero of the War of 1812. In 1814, he defeated the British on Lake Champlain at Plattsburgh, New York, in one of the most decisive battles ever fought by the United States Navy. When he took command of the Lake Champlain naval squadron in 1812, he found small, poorly armed vessels that lacked supplies and had untrained crews. After two years of preparations, he entered the harbor at Plattsburgh, carefully stationed his ships, and awaited the British. By fighting at anchor from an advantageous position rather than in open water, he captured the entire British fleet. His victory halted the British invasion of New York state and forced the British Army to retreat into Canada.

Macdonough was born in New Castle County, Delaware. He became a midshipman at 16. Macdonough became commander of the Mediterranean Squadron in 1824. Michael J. Crawford

See also War of 1812 (Lake Champlain).

MacDowell, Edward Alexander (1861-1908), was an American composer and pianist. During his lifetime, many people considered him the greatest composer in the history of American music. Today, he is primarily known for such short piano pieces as "To a Wild Rose" and "To a Water Lily." Both were part of a collection called *Woodland Sketches* (1896).

MacDowell's works reflect the rich harmonies of the European romantic composers, notably Edvard Grieg of Norway. MacDowell dedicated his *Norse Sonatas* (1900) and *Keltic Sonatas* (1901) to Grieg. MacDowell also composed many songs and a few orchestral works.

MacDowell was born in New York City. He headed the newly formed music department at Columbia University from 1896 to 1904. Leonard W. Van Camp

Mace is a liquid tear gas that can be sprayed from a pressurized container. It causes a burning sensation and makes the eyes fill with tears. When sprayed on the skin or eyes, Mace can cause temporary disability, but it usually has no lasting effects. If inhaled, it may cause severe, though temporary, irritation of the air passages in the lungs, resulting in coughing and choking. Mace can be ineffective when sprayed on a person who is under the influence of stimulant drugs. *Mace* and *Chemical Mace* are trademarks of Mace Security International, But other companies make similar liquid chemical irritants.

Many police departments use Mace and other irritant sprays to help control riots and violent demonstrations. Some civilians carry containers of Mace for self-defense. Such sprays can be used on individual targets without affecting people nearby. Frances M. Lussier

Mace is a club-shaped staff used as a symbol of authority. It is most often seen in legislatures where it is used chiefly to restore order. The mace originally was a weapon of the Middle Ages. It was a long-handled club, heavily weighted at one end. As the science of war developed, the weighted end became an iron ball. Archers and other unmounted warriors used the mace as a hand arm. Sergeants at arms, who guarded kings and other officials, and some church officials carried maces. Gradually the mace gained a ceremonial character. The mace used in the United States House of Representatives is about 3 feet (90 centimeters) long. It consists of ebony rods bound with a silver band. A longer ebony rod in the center of the bundle has a silver globe mounted on it with a silver eagle on top. Whitney Smith

Mace is a highly flavored spice. It is the dried form of the red, netlike *aril,* or membrane, covering the nutmeg seed kernel (see **Nutmeg**). When fresh, this membrane is fleshy and smells and tastes like nutmeg. It is removed from the kernel and dried in the sun for its use as a spice. As it dries, the membrane turns orange-yellow and acquires a strong aroma. Mace is sold in whole or ground form. James E. Simon

Macedonia is a historic region on the Balkan Peninsula of southeastern Europe. It covers all of a country that is also called Macedonia, plus parts of northern Greece and southwestern Bulgaria. The country of Macedonia has an area of 9,928 square miles (25,713 square kilometers). Greek Macedonia covers 13,206 square miles (34,203 square kilometers), and Bulgarian Macedonia 2,502 square miles (6,480 square kilometers). The region of Macedonia became powerful in ancient times, when Macedonian leader Alexander the Great conquered much of Asia and spread Macedonian and Greek culture throughout his empire.

The earliest known settlements in what is now Macedonia were villages established about 6200 B.C. Many different peoples settled in the region over the next several thousand years. The people living there eventually came to be known as *Macedones,* and the region as

WORLD BOOK map
Macedonia

Macedonia. The name *Macedones* comes from the Greek word *makednon,* meaning *high*—a reference to the group's mountainous homeland.

The first known rulers of the Macedonians were members of the Argead *dynasty* (family of rulers), founded by King Perdiccas I about 650 B.C. During the 500's and 400's B.C., the Argeads expanded Macedonian rule into nearby regions.

King Philip II, an Argead, continued this expansion and eventually invaded central Greece. By 338 B.C., Philip controlled all of Greece. With these acquisitions, Macedonia gained valuable natural resources.

Philip was assassinated in 336. His son, Alexander, became king. Crowned King Alexander III, Philip's son became known as Alexander the Great. Alexander conquered the Persian Empire, which stretched from the Mediterranean Sea to India. The arts flourished under Alexander's rule. Macedonia also became extremely wealthy after acquiring the riches of the defeated Persian Empire. Alexander died in 323 B.C., without leaving a strong successor. Political unity soon collapsed, as Macedonia's army generals divided up the empire.

Macedonia became a Roman province in the 140's B.C. When the Roman Empire split into two parts in A.D. 395, Macedonia remained part of the East Roman, or Byzantine, Empire. In the A.D. 500's, Slavs from eastern Europe settled in Macedonian towns. Bulgars from central Asia conquered Macedonia in the late 800's. In 1018, the Byzantine Empire regained control. The region came under Serbian rule in the early 1300's. But in 1371, the Ottoman Empire conquered the region. Macedonia remained part of the Ottoman Empire for over 500 years.

By the late 1800's, the Ottoman Empire had begun to collapse. In 1878, Bulgaria controlled Macedonia briefly. But most of Macedonia was returned to Ottoman rule that same year.

At the end of the Second Balkan War (1913), Macedonia was divided among Serbia, Greece, and Bulgaria. Serbian Macedonia became the Yugoslav republic of Macedonia in 1946. The republic became an independent country in 1991. Sabrina P. Ramet

Macedonia is a country in southeastern Europe. From 1946 to 1991, it was the southernmost of the six republics that made up the federal state of Yugoslavia. In 1991, after the republics of Croatia and Slovenia broke away from Yugoslavia, Macedonia also declared its independence. Macedonia is also referred to as the Former Yugoslav Republic of Macedonia (FYROM) to distinguish it from the region of Macedonia in northern Greece.

The Macedonian ethnic group makes up the largest part of the country's population. Other major ethnic groups include Albanians and Turks. Skopje is Macedonia's capital and largest city.

From 1945 to 1990, Communists controlled all Yugoslavia, including Macedonia. In 1990, non-Communists gained control of Macedonia's government.

Facts in brief

Capital: Skopje.
Official languages: Macedonian and Albanian.
Official name: Republika Makedonija (Republic of Macedonia).
Area: 9,928 mi² (25,713 km²). *Greatest distances*—north-south, 105 mi (170 km); east-west, 135 mi (215 km).
Elevation: *Highest*—Mount Korabit, 9,026 ft (2,751 m) above sea level. *Lowest*—Vardar River at southern border, 230 ft (70 m) above sea level.
Population: *Estimated 2002 population*—2,048,000; density, 206 persons per mi² (80 per km²); distribution, 59 percent urban, 41 percent rural. *1994 census*—1,949,644.
Chief products: *Agriculture*—apples, cattle, corn, cotton, grapes, hogs, peaches, plums, poultry, sheep, tobacco, wheat. *Manufacturing*—cement, iron and steel, refrigerators, sulfuric acid, textiles, tobacco products. *Mining*—chromium, copper, iron ore, lead, manganese, uranium, zinc.
National anthem: "Denes nad Makedonija se ragja" ("A New Sun Rises over Macedonia Today").
Flag: The flag is red and has a yellow disk in the center with eight yellow rays extending from the disk to the flag's edges. See Flag (picture: Flags of Europe).
Money: *Basic unit*—denar. One hundred deni equal one denar.

Government. A president is the highest official in Macedonia and is elected by the people to a four-year term. The Assembly of the Republic of Macedonia, the nation's lawmaking body, consists of 120 members who are elected by the people to four-year terms. The president plays a leading role in establishing foreign policy. The president appoints a prime minister to handle day-to-day operations of the government. The Assembly must approve the appointment. The country's leading political parties include the Internal Macedonian Revolutionary Organization—Democratic Party for Macedonian National Unity, the Social Democratic Alliance of Macedonia (a group of former Communists), and the Party of Democratic Prosperity of Albanians in Macedonia. The country is divided into districts called *opštini* for purposes of local government. Local assemblies govern opštini.

Macedonia's highest court is the Supreme Court. The Assembly appoints justices of the Supreme Court. About 9,000 men and women serve in Macedonia's armed forces.

People. About two-thirds of the people are Macedonian Slavs. About a fifth are Albanians, most of whom live in western Macedonia. The country has smaller numbers of Turks, Gypsies, and Serbs. Most ethnic Macedonians and Serbs are Eastern Orthodox Christians. Most Turks and Albanians are Muslims. The country's official languages are Macedonian, a South Slavic language closely related to Serbo-Croatian and Bulgarian, and Albanian.

Many of Macedonia's city dwellers live in apartments in high-rise buildings. In rural villages, people have homes built of stone, red brick, or concrete brick.

Favorite Macedonian dishes include cold cucumber soup, garlic soup, *sarma* (stuffed grape leaves), and *sataraš*—a pork and veal dish spiced with onions and red peppers. The national drink is *šljivovica,* a plum brandy.

Almost all of the country's adults can read and write. Children are required to attend school from the ages of 7 to 15. Macedonia has a university at Skopje and several other institutions of higher education.

Traditional Macedonian music shows many Turkish features introduced during Ottoman rule from the mid-1300's to the early 1900's. Popular folk dances include

Railroad
National capital
Other city or town
Elevation above sea level

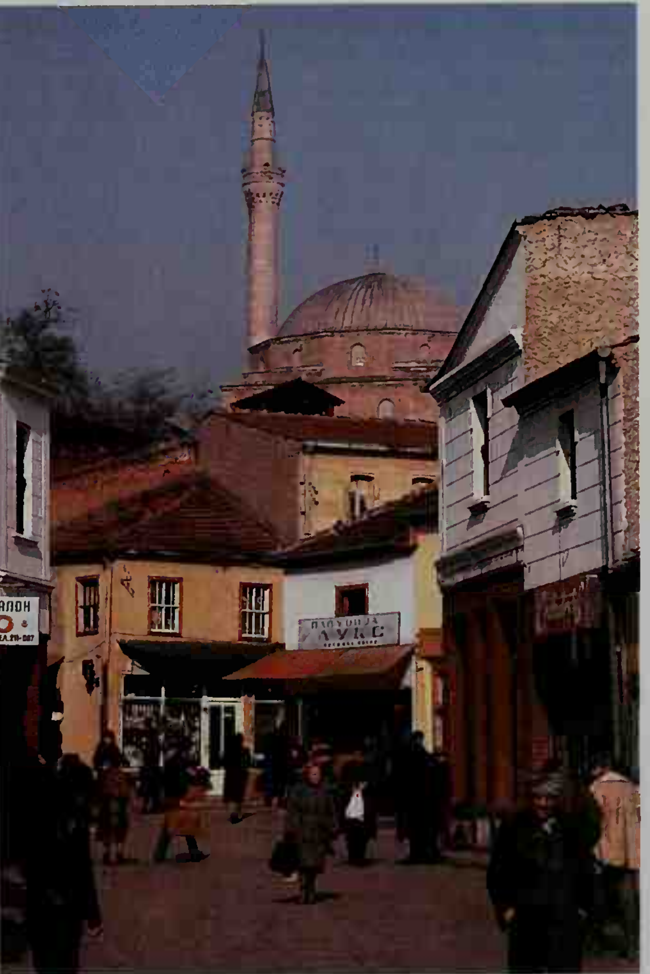
WORLD BOOK maps

the *oro,* a type of circle dance. Soccer is the country's most popular sport.

Land and climate. Macedonia is a rugged country, consisting largely of mountains and hills. Much of it occupies a plateau that lies between 2,000 and 3,000 feet (600 to 900 meters) above sea level. Some of Macedonia's mountains reach heights of more than 8,000 feet (2,500 meters). Mount Korabit, the highest peak, rises 9,026 feet (2,751 meters) along the western border. Forests of beech, oak, and pine grow in many areas of the country, particularly in the west. The Vardar is Macedonia's longest river. It rises in the northwest and flows through central and southern Macedonia.

Macedonia has cold, snowy winters. Summers are hot in the mountain valleys but cooler at higher elevations. Temperatures in Skopje average 34 °F (1 °C) in January and 75 °F (24 °C) in July. The city has an average annual rainfall of 21 inches (55 centimeters).

Economy. The government owns many factories and other businesses in Macedonia. About 40 percent of Macedonians work in industry and less than 10 percent in agriculture. Such service industries as government, health care, and trade employ most other Macedonians.



Macedonian factories produce cement, iron and steel, refrigerators, sulfuric acid, textiles, and tobacco products. The country's mines yield chromium, copper, iron ore, lead, manganese, uranium, and zinc.

Farms cover about a fourth of Macedonia. Chief crops include corn, cotton, tobacco, and wheat. Farmers also grow apples, grapes, peaches, and plums. Some farmers raise cattle, hogs, poultry, and sheep. Logging is also an important economic activity in rural areas.

Paved roads connect most cities and large towns in Macedonia. A railroad system links Macedonia with Yugoslavia and Greece. The country has airports at Skopje and Ohrid. Leading daily newspapers in Macedonia include *Večer* and *Nova Makedonija*—both of Skopje. Most families own a television and one or more radios.

History. Until the early 1900's, the history of what is now the country of Macedonia was tied to that of the larger, historic area, also called Macedonia. The historic region of Macedonia includes the country of Macedonia and parts of northern Greece and southwestern Bulgaria. For information on historic Macedonia, see **Macedonia** (historic region).

By the late 1800's, historic Macedonia had been part of the Turkish-ruled Ottoman Empire for more than 500 years. But the Ottoman Empire had begun to fall apart, and Bulgaria and Serbia competed for possession of Macedonia. Bulgaria claimed that Macedonians were Bulgarians, while Serbia insisted they were "south Serbs." Bulgaria, Greece, and Serbia took Macedonia from the Ottoman Empire in the First Balkan War (1912-1913). In 1913, in the Second Balkan War, Bulgaria fought Greece, Montenegro, Romania, Serbia, and the

Skopje, Macedonia's capital, features many small shops along cobblestoned streets in its old town district, *above.* A domed mosque with a tower called a *minaret* rises in the background.

Ottoman Empire for control of the region. The war left Serbia with north and central Macedonia. Eastern Macedonia came under Bulgarian rule, and Greece gained southern Macedonia.

In 1918, Serbian Macedonia became part of the Kingdom of the Serbs, Croats, and Slovenes, which was renamed Yugoslavia in 1929. After World War II ended in 1945, a Communist government led by Josip Broz Tito took control of Yugoslavia. In 1946, the part of the Macedonia the Serbs had controlled became one of the six republics of the federal state of Yugoslavia.

In the late 1980's, Communist power began to decline. In 1990, the Communists allowed other political parties to form. Later that year, Macedonia held its first multiparty elections, and the Communists lost control of the government. Macedonia, Croatia, and Slovenia declared their independence from Yugoslavia in 1991.

Many nations soon recognized Croatia and Slovenia as independent countries. But Greek protests halted recognition of Macedonia by most other nations. Greece feared that Macedonia would claim land in the region of Macedonia in northern Greece. In 1993, Macedonia and Greece agreed to a compromise by which Macedonia was admitted to the United Nations under the temporary name of the Former Yugoslav Republic of Macedonia.

Greece applied a trade embargo to Macedonia in 1994 which seriously hurt the country's economy. Greece lifted the embargo in 1995 in exchange for Macedonia's pledge to change its flag and to make no claims to territory outside its borders.

In February 2001, rebels began fighting for greater equality for Albanians within Macedonia. Attempts to resolve the conflict through negotiations failed, and the Macedonian government launched attacks on rebel-held villages. In July, both sides agreed to a cease-fire and resumed negotiations. But the violence continued.

In August 2001, leaders from both sides signed a peace accord that called for greater rights for Macedonia's Albanian population. Peacekeeping troops from the North Atlantic Treaty Organization (NATO) then arrived to help disarm the rebels. In November, Macedonia's Assembly approved a new constitution that granted the country's Albanians greater rights. Sabrina P. Ramet

MacGregor, Robert. See **Rob Roy.**

Mach, *mahk,* **Ernst** (1838-1916), was an Austrian physicist and psychologist. He studied the action of bodies moving at high speeds through gases, and developed an accurate method for measuring their speeds in terms of the speed of sound. This method is important in problems of supersonic flight.

Mach's work remained obscure until the speed of aircraft began to approach the speed of sound. Then the term *Mach number* came to be used as a measure of speed. *Mach 0.5* is half the speed of sound, or *subsonic. Mach 1* is the speed of sound, or *transonic. Mach 2* is twice the speed of sound, or *supersonic,* and so on (see **Aerodynamics** [Supersonic aerodynamics]).

Mach studied the historical development of the ideas on which the science of mechanics is based. He taught that a scientific law was only a correlation between observed data. He was born on Feb. 18, 1838, at Turas, Moravia (now in the Czech Republic). Arthur I. Miller

Machado de Assis, *mah SHAH du dih ah SEES,* **Joaquim Maria** (1839-1908), was a Brazilian author. His many novels and short stories combine a realistic style with sensitive psychological analyses of the characters. In his works, he experimented with the use of humor, irony, and different points of view.

Machado wrote chiefly about urban, middle-class Brazilians of the 1800's. In his stories, he explored the universal aspects of human nature, analyzed the reasons for the ways people think and act, and raised questions about life's meaning. His first major novel was *Memórias Póstumas de Bras Cubas* (1881), which was translated as *Epitaph of a Small Winner.* His other novels include *Philosopher or Dog?* (1891), *Dom Casmurro* (1900), *Esau and Jacob* (1904), and *Memorial of Ayres* (1908). Some shorter fiction was translated into English and published after his death in *The Psychiatrist and Other Stories* (1963). Machado was born in Rio de Janeiro on June 21, 1839, and died on Sept. 29, 1908. Earl E. Fitz

Machaut, *ma SHOH,* **Guillaume de,** *gee YOHM duh* (1300?-1377), was a medieval French composer and poet. His best-known composition is his Mass, the earliest complete Mass for four voices by a single composer. He also wrote many French and Latin songs for one to four voices. The songs have elegant and expressive melodies, and often use offbeat rhythmic effects known as *syncopation.* Machaut's songs follow strict poetic forms. A typical song has its chief melody sung by the highest voice, accompanied by one or two voices or instruments in the tenor range. Machaut also wrote many songs for only one voice, like the songs of the poet-musicians called *troubadours* (see **Troubadour**).

Machaut was born near Reims. He often traveled with royal courts and with armies. He was a *canon* (priest attached to a cathedral) at Reims, and he also served the kings of Bohemia and France. Joscelyn Godwin

Machiavelli, *MAK ee uh VEHL ee* or *MAH kyah VEHL lee,* **Niccolò** (1469-1527), was an Italian statesman and writer whom many people consider the father of modern political science. He ranks as one of the most important political thinkers of the Renaissance, a period of great intellectual activity between the 1300's and the 1600's. The experience he acquired as a government official and his study of history led him to view politics in a new way. The political writers of the Middle Ages treated politics idealistically, within a religious framework. But Machiavelli sought to explain politics realistically, based on his view of human nature within a historical framework.

Machiavelli viewed the state as an organism with its ruler as the head and its people as the body. He maintained that a healthy state is unified, orderly, and in balance, and that its people have happiness, honor, strength, and security. But an unhealthy state is disorderly and unbal-

Detail of *Niccolò Machiavelli* (about 1570), an oil painting on canvas by Santi di Tito; Palazzo Vecchio, Florence, Italy (Alinari/EPA)

Niccolò Machiavelli

anced, and may require strong measures to restore it to normal. Machiavelli called for a leader to use any means necessary to preserve the state, resorting to cruelty, deception, and force if nothing else worked. As a result, many people thought he supported the use of cruelty and deceit in politics. The word *Machiavellian* came to mean *cunning* and *unscrupulous.*

Machiavelli explained most of his ideas in *The Prince,* his best-known book, which was written in 1513 and published in 1532. This book describes the methods by which a strong ruler might gain and keep power. Machiavelli's other works include *Discourses upon the First Ten Books of Livy* (1517 or 1518) and *The Art of War* (1520 or 1521). He also wrote plays and poems.

Machiavelli was born in Florence, Italy. In 1498, he was appointed secretary of the second highest governing body in the Florentine republic. His duties consisted mainly of conducting diplomatic missions. He also organized a militia for the republic. In 1512, the republic collapsed. The Medici family, which had ruled Florence earlier, was then restored to power. Machiavelli was arrested, tortured, and imprisoned on suspicion of plotting against Medici rule, but he was released after less than a year. John H. Geerken

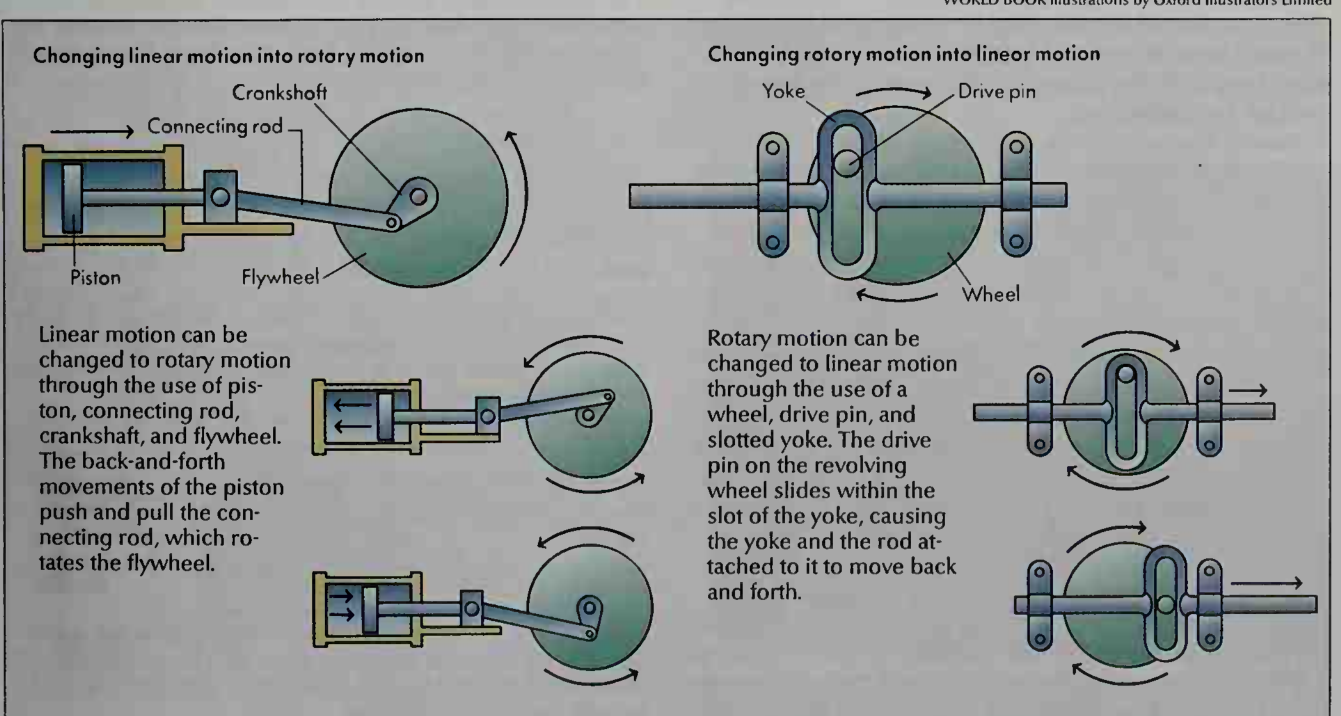
Machine is a device that does work. Machines are designed to make life easier for us. Some machines perform tasks that would be impossible to do without them. We use machines all the time. Industries use giant drill presses, lathes, and presses to make the products we use. Businesses depend on typewriters, computers, and other office machines. Automobiles, buses, and airplanes transport people swiftly over great distances. Trucks, railroads, and ships haul goods to and from markets. Without machines, the residents of our cities would find it more difficult to live, and farmers could not raise enough food to feed us.

People have constructed a wide variety of machines to satisfy their needs. Early people made stone axes that served as weapons and tools. The machines that were gradually developed gave people great control over their *environment* (physical surroundings). To operate these improved machines, people harnessed the energy of falling water and of such fuels as coal, oil, and the atom. Today, we use so many machines that the age we live in is often called the *machine age.*



Principles of machines

A machine produces force and controls the direction and the motion of force. But it cannot create energy. A machine can never do more work than the energy put into it. It only transforms one kind of energy, such as electrical energy, and passes it along as mechanical energy. Some machines, such as diesel engines or steam turbines, change energy directly into mechanical motion. For example, the energy of steam rushing through the wheels of a turbine produces rotary motion. The mechanical energy of the turbine can be used to drive a generator that produces electricity. Other machines simply transmit mechanical work from one part of a device to another part. They include the six simple machines that are described below.

A machine's ability to do work is measured by two factors. They are (1) efficiency and (2) mechanical advantage.

How machines change the direction of motion

WORLD BOOK illustrations by Oxford Illustrators Limited

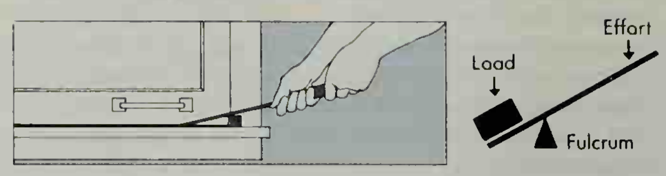
Linear motion can be changed to rotary motion through the use of piston, connecting rod, crankshaft, and flywheel. The back-and-forth movements of the piston push and pull the connecting rod, which rotates the flywheel.

Rotary motion can be changed to linear motion through the use of a wheel, drive pin, and slotted yoke. The drive pin on the revolving wheel slides within the slot of the yoke, causing the yoke and the rod attached to it to move back and forth.

Efficiency. The efficiency of a machine is the ratio between the energy it supplies and the energy put into it. No machine can operate with 100 per cent efficiency because the friction of its parts always uses up some of the energy that is being supplied to the machine. Although friction can be decreased by oiling any sliding or rotating parts, all machines produce some friction. For this reason, a perpetual-motion machine is impossible (see **Perpetual motion machine**).

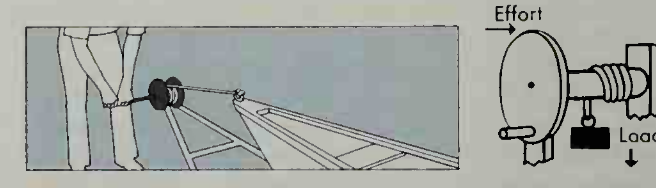
A simple lever is a good example of a machine that has a high efficiency (see **Lever**). The work it puts out is almost equal to the energy it receives, because the energy used up by friction is quite small. On the other hand, an automobile engine has an efficiency of only about 25 per cent, because much of the energy supplied by the fuel is lost in the form of heat that escapes into the surrounding air. See **Efficiency.**

Mechanical advantage. In machines that transmit only mechanical energy, the ratio of the force exerted by the machine to the force applied to the machine is known as *mechanical advantage.* Mechanical advantage can be demonstrated with a crowbar, which is a type of lever. When one end of the crowbar is directly under the weight, a part of the crowbar must rest on a *fulcrum* (support). The closer the fulcrum is to the load, the less the effort required to raise the load by pushing down on the handle of the crowbar, and the greater the mechanical advantage of the crowbar. For example, if the load is 200 kilograms, and the distance from the load to the fulcrum is one fourth of the distance from the handle to the fulcrum, it will take 50 kilograms of effort to raise the load. Therefore, the mechanical advantage will be four to one. But the distance the load will be moved will be only one-fourth of the distance through which the effort is applied.



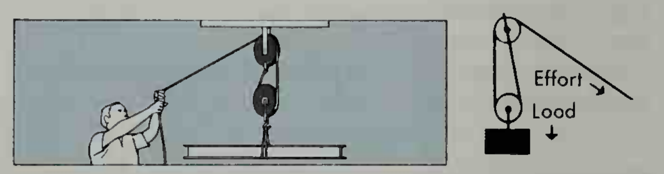
Six simple machines

Most machines consist of a number of elements, such as gears and ball bearings, that work together in a complex way. But no matter how complex they are, all machines are based in some way on six types of simple machines. These six types of machines are the lever, the wheel and axle, the pulley, the inclined plane, the wedge, and the screw.



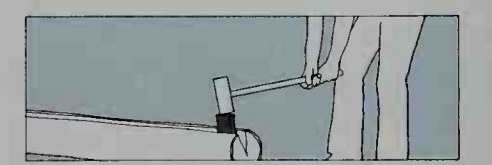
Lever. There are three basic types of levers, depending on where the effort is applied, on the position of the load, and on the position of the fulcrum. In a first-class lever, such as a crowbar, the fulcrum is between the load and the applied force. In a second-class lever, such as a wheelbarrow, the load lies between the fulcrum and the applied force. In a third-class lever, the effort is applied between the load and the fulcrum. For example, when a person lifts a ball in the palm of the hand, the load is at the hand and the fulcrum is at the elbow. The forearm supplies the upward force that lifts the ball. See **Lever.**

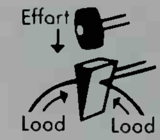
Wheel and axle. The wheel and axle is essentially a modified lever, but it can move a load farther than a lever can. In a windlass used to raise water from a well, the rope that carries the load is wrapped around the axle of the wheel. The effort is applied to a crank handle on the side of the wheel. The center of the axle serves as a fulcrum. The mechanical advantage of the windlass depends upon the ratio between the radius of the axle and



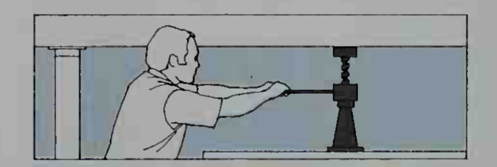
Six simple machines

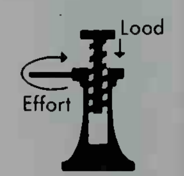
The lever is one of the earliest and simplest machines. Its advantage lies in the short distance between the fulcrum (pivotal point) and load, and in the long distance between the fulcrum and the point where effort is applied.





The wheel and axle has a rope attached to the axle to lift the load. The crank handle is the point where effort is applied. The effort is smaller than the load because it is at a greater distance from the axle which is the fulcrum.





The pulley consists of a wheel with a grooved rim over which a rope is passed. It is used to change the direction of the effort applied to the rope. A block and tackle uses two or more pulleys to reduce the amount of effort needed to lift a load.

The inclined plane makes it easier to slide or skid a load upward than to lift it directly. The longer the slope, the smaller the effort required. The amount of work, however, is no less than if the load were lifted directly upward.

The wedge, when struck with a mallet or sledge, exerts a large force on its sides. A gently tapering, or thin, wedge is more effective than a thick one. The mechanical advantage of the wedge is of great importance.

The screw is a spiral inclined plane. The jackscrew is a combination of the lever and the screw. It can lift a heavy load with relatively small effort. Therefore, it has a very high mechanical advantage for practical purposes.

the distance from the center of the axle to the crank handle. The wheel-and-axle machine has important applications when it is used to transport heavy goods by rolling rather than by sliding. The wheel itself is regarded as one of the most important inventions of all time. It is widely used in all types of machinery and motor vehicles. See **Wheel and axle.**

Pulley. A pulley is a wheel over which a rope or belt is passed. It is a form of the wheel and axle. The mechanical advantage of a single pulley is one, because the downward force exerted on the rope equals the weight lifted by the other end of the rope that passes over the pulley. The main advantage of the single pulley is that it changes the direction of the force. For example, to lift a load, a person can conveniently pull down on a rope, using the weight of the body. When one pulley is attached to a support and another is attached to the load and allowed to move freely, a definite mechanical advantage is obtained. See **Pulley.**

Inclined plane. The inclined plane is such a simple device that it scarcely looks like a machine at all. The average person cannot raise a 200-pound box up 2 feet into the rear of a truck. But by placing a 10-foot plank from the truck to the ground, a person could raise the load easily. If there were no friction, the force required to move the box would be exactly 40 pounds. The mechanical advantage of an inclined plane is the length of the incline divided by the vertical rise. The mechanical advantage increases as the slope of the incline decreases. But the load will then have to be moved a greater distance. By adding rollers, it is possible to make a roller conveyor that will reduce friction and have great efficiency. See **Inclined plane.**

Wedge. The wedge is an adaptation of the inclined plane. It can be used to raise a heavy load over a short distance or to split a log. The wedge is driven by blows from a mallet or sledge hammer. The effectiveness of the wedge depends on the angle of the thin end. The smaller the angle, the less the force required to raise a given load. See **Wedge.**

Screw. The screw is actually an inclined plane wrapped in a spiral around a shaft. The mechanical advantage of a screw is approximately the ratio of the circumference of the screw to the distance the screw advances during each revolution.

A *jackscrew,* such as those used to raise homes and other structures, combines the usefulness of the screw and the lever. The lever is used to turn the screw. The mechanical advantage of a jackscrew is quite high, and only a small effort will raise a heavy load. See **Screw.**

Designing machines

By combining the principles of simple machines, engineers develop new and specialized machines. They choose materials for the various parts of the machine that resist stress, friction, and *corrosion* (wear from chemicals). Engineers also design machines to be safe and efficient. Richard M. H. Cheng

Machine gun is an automatic weapon that can fire from 400 to 1,600 rounds of ammunition each minute. Machine gun barrels range in size from .22 caliber to 20 millimeters. Ammunition is fed into the gun from a cloth or metal belt, or from a cartridge holder called a *magazine.* Because machine guns fire so rapidly, they must be cooled by air. Machine guns are heavy weapons and are usually mounted on a support.

Operation. In all machine guns, extremely high gas pressure provides the operating energy for the firing cycle. The cycle begins when the propellant charge in the cartridge case burns. This combustion creates the gas pressure that is used in the *blowback, gas,* and *recoil* operating systems. All three systems fire the projectile through the *bore* of the barrel, eject the cartridge case, place a new cartridge in the firing chamber, and ready the mechanism to repeat the cycle.

In the *blowback system,* the operating energy comes

William Allen, Photri

from the cartridge case as the case is forced to the rear by the gas pressure. The case moves against the bolt, driving the bolt backward against a spring. The case is ejected, and the compressed spring drives the bolt forward. As the bolt moves forward, it cocks the firing mechanism, picks up a new cartridge, carries it into the chamber, and the cycle begins again.

In the *gas system,* the gas pressure drives a piston against the bolt. The bolt is driven to the rear, providing energy for a cycle like that of the blowback system.

In the *recoil system,* the bolt locks to the barrel when the gun is fired. These parts remain locked together as they are forced to the rear by the gas pressure. This movement provides energy to operate the gun.

Ground weapons. The 7.62-millimeter M60 machine gun is a major infantry weapon. It is air-cooled and gas-operated, and fires about 600 rounds a minute. The M60 replaced the Browning machine gun, an important weapon in World Wars I and II, and the Korean War.

Aircraft weapons. By the close of World War I, several types of machine guns were mounted on airplanes. These types included the Vickers, Maxim, Hotchkiss, Colt-Martin, and Lewis. Some machine guns were synchronized to fire in between the blades of propellers.

During World War II, fighters and bombers carried machine guns as armament. They also carried automatic cannon up to 20 millimeters in size. During the Vietnam War, helicopters called *gunships* carried machine guns or cannon. Today, most fighter planes and gunships carry rockets for air-to-air and air-to-ground use. Bombers use machine guns mounted in groups of two or four in power-driven turrets. The Vulcan 20-millimeter aircraft cannon has six rotating barrels. It can fire more than a ton of metal and explosives each minute.

Antiaircraft weapons. The .50-caliber Browning machine gun was used as an antiaircraft weapon during World War II. It was used alone, or in groups of two or four. Large-caliber automatic cannon that fired explosive shells were also developed as antiaircraft weapons. The 20-millimeter, Swiss-made Oerlikon gun was used on U.S. Navy ships. It was a self-fed, self-firing cannon that could fire 600 rounds a minute.

Early machine guns

WORLD BOOK illustrations by Robert Addison

Gatling gun

Richard Gatling built a hand-cranked machine gun in 1862.

Montigny mitrailleuse

The Montigny mitrailleuse was a 37-barrel machine gun.

Maxim gun

Hiram Maxim made the first fully automatic machine gun.

History. A type of machine gun appeared as early as the 1500's. It consisted of several guns bound together in a bundle or spread out in a row. A device that was fitted to the gun barrels caused them to fire simultaneously or in series. But little success was achieved until the Civil War, when many quick-fire guns appeared. Practical, rapid-fire, mechanical guns were used in the Franco-Prussian War, when soldiers operated them with a crank or lever. The French *Montigny mitrailleuse* and the American *Gatling* were among the more successful of these guns.

In 1883, Hiram Maxim, an American-born inventor, developed the first entirely automatic machine gun to gain wide acceptance. By the time of World War I, many different types of machine guns had come into use.

Joel D. Meyerson

See also **Gatling, Richard J.; Maxim, Sir Hiram Stevens.**

Machine tool is a power-driven machine used to shape metal. Basic machine tools use mechanical power to bend, cut, drill, grind, hammer, plane, and squeeze metal into desired shapes. More advanced machine tools use such power sources as electrical or chemical energy, heat, magnetism, and ultrasound. People who operate machine tools are called *machinists.*

Machine tools play an important part in the manufacture of almost all metal products. Machinists use them in making parts for such products as automobiles, radios, refrigerators, and television sets. Many other products are made by machines that were manufactured by machine tools. These include such products as books, furniture, and textiles.

There are about 500 kinds of machine tools. Some perform a single operation, such as grinding or drilling. Others, called *machining centers,* carry out several kinds of tasks. Machining centers have automatic tool changers and may use more than 100 tools.

Machine tools can be linked together to form a *flexible manufacturing system* (FMS). Each of the tools in an FMS performs a different metalworking operation. The metal being machined, called a *workpiece,* is moved from one tool to the next by conveyors, robots, and other automatic equipment. A single FMS can manufacture a variety of parts.

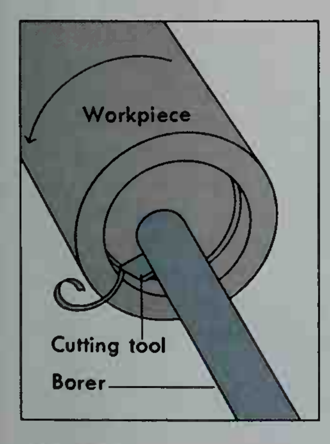
Machine tools come in a wide range of sizes. A machinist's choice of size is based on the size of the largest workpiece to be machined.

Basic machine tool operations

There are two chief kinds of machine tool operations: (1) metal removal and (2) metal forming. Basic metal removal operations involve either the cutting away or the *abrasion* (wearing away) of part of the workpiece. In metal forming, the workpiece is shaped without the removal of any material from it.

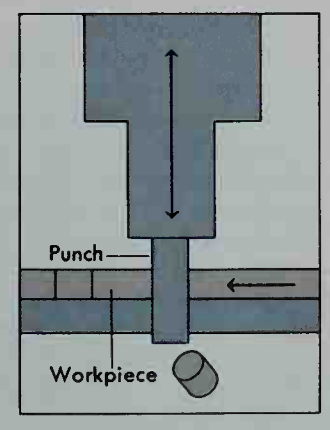
Metal removal. There are six basic types of metal removal processes. They are (1) turning; (2) hole machining; (3) milling; (4) sawing; (5) planing, shaping, and broaching; and (6) abrasive processes.

Turning is used chiefly to cut metal into round shapes. Turning machines are the most common machine tools in the United States. They manufacture gear blanks, shafts, wheels, and many other metal parts.



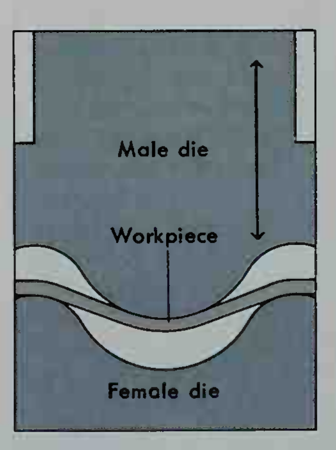
The *lathe* is the basic turning machine. On a lathe, the workpiece is fastened to a rotating spindle, and the cutting tool is mounted at the side of the workpiece. The tool moves against the rotating workpiece, peeling metal until the workpiece has the desired shape. A *turret lathe* has several kinds of cutting tools mounted on a revolving toolholder called a *turret.* This lathe can perform various cutting operations, one after the other.

Some turning machines have several spindles and cutting tools that operate at the same time. Such *multispindle machines* perform various operations at once on several workpieces. The machine moves each workpiece from one cutting tool to the next until all the operations have been performed.

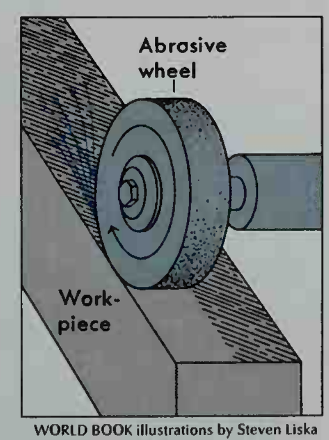


Hole machining includes drilling, boring, reaming, and tapping. In *drilling,* round holes up to 3 inches (7.5 centimeters) in diameter are cut in a piece of metal. These holes, cut by a rotating *twist drill,* may be as small as a few thousandths of an inch in diameter.

In most machine shops, twist drills are mounted on large machines called *drill presses.* The machinist places the workpiece on a table beneath the drill and lowers the drill into the metal. The bit of the drill has several sharp cutting edges. Two or more spiral grooves along the bit help remove metal shavings from the hole.

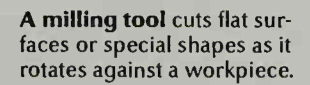


In *boring,* round holes greater than 3 inches (7.6 centimeters) in diameter are cut. Boring is also used to en-

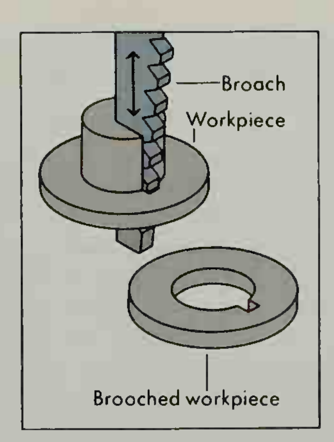


A borer cuts and smooths round holes. Its cutting tool has a single sharp edge.

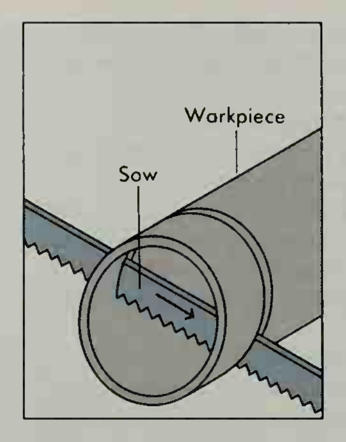
A punch press is a forming machine that stamps holes into sheet metal.



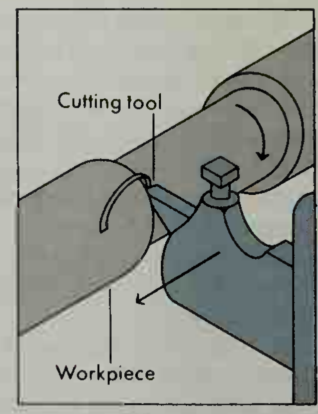
Press brakes form metal into a desired shape by pressing it between two dies.



WORLD BOOK illustrations by Steven Liska



A grinding wheel rubs against the surface of a workpiece to make it smooth.



A milling tool cuts flat surfaces or special shapes as it rotates against a workpiece.

A broach changes the shape of a hole. It is pushed or pulled through a workpiece.

A saw cuts a piece of metal to a certain length or into a desired shape.

WORLD BOOK illustrations by Steven Liska

A turning machine has a cutting tool that peels metal from a rotating workpiece.

large and *finish* (smooth) holes already drilled.

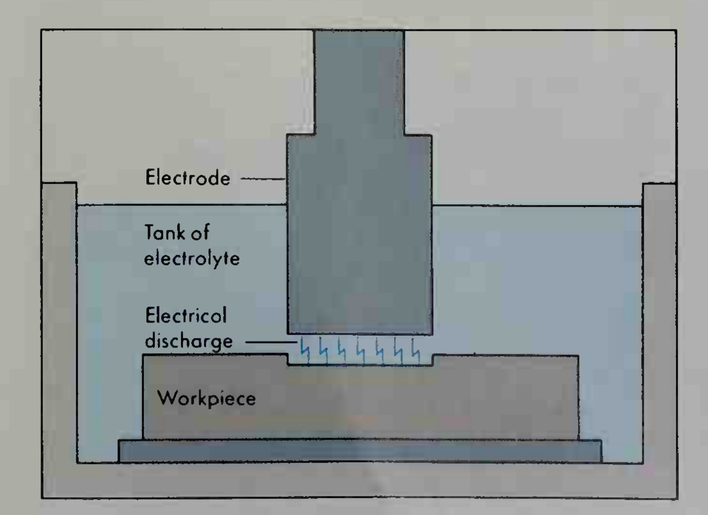
Boring machines have a cutting tool with only one sharp edge. On small boring machines, the tool revolves and the workpiece remains stationary. On large machines, the tool is stationary and the workpiece revolves.

The process of *reaming* consists of smoothing the inside of a hole. *Tapping* involves the cutting of a screw thread inside a hole (see Screw).

To cut deep holes, machinists use special processes in which a single- or multiple-edged tool mounted at the end of a bar is driven into the workpiece. These processes involve the rotation of the tool, the workpiece, or both. During the operation, a fluid is forced into the hole to flush out shavings cut from the workpiece.

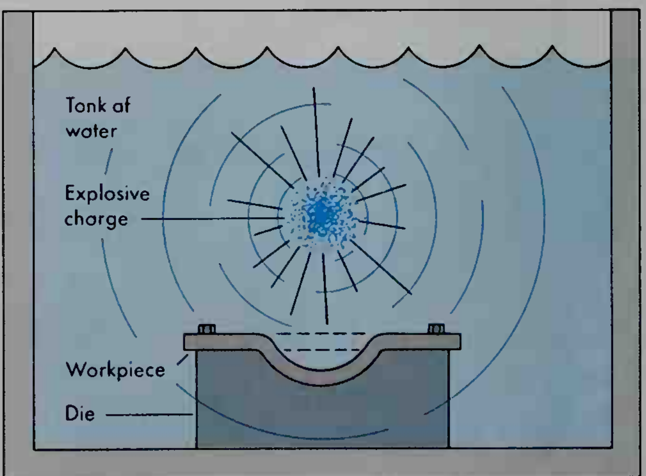
Milling. In this operation, a round tool with several cutting edges rotates against a workpiece. The cutting tool of most milling machines looks like a wheel with teeth projecting out of it. This tool makes flat surfaces on metal. Machinists use special milling tools to cut such shapes as those of bevels, gear teeth, and slots.

Some milling machines manufacture metal parts small enough to fit in a person's hand. Others, such as *special contour milling machines,* produce airplane wing sections as long as 80 feet (24 meters).



Sawing consists of machining a piece of metal with a cutting tool that has sharp teeth along one edge. There are two types of machine-tool sawing, *cutoff sawing* and *contour sawing.* Machinists use cutoff sawing to cut metal bars to a certain length. Contour sawing cuts flat pieces of metal into the desired shape.

Planing, shaping, and broaching. Planing smooths flat surfaces of large pieces of metal. It resembles smoothing wood with a hand plane. But the cutting tool is stationary as the metal moves back and forth beneath it. Shaping flattens uneven surfaces and cuts slots. The cutting tool moves back and forth over a stationary workpiece. Broaching shapes holes in a piece of metal. For example, it can change round holes to square ones. A broach is a long metal bar with rows of teeth on it. Each tooth cuts a little deeper than the one before. A broach is pulled or pushed through a hole, and the teeth cut the metal to the desired shape.



Milling has replaced planing and shaping almost entirely. The cutting tools of milling machines can smooth metal surfaces faster than those of planers or shapers.

Abrasive processes include grinding, lapping, and honing. In *grinding,* metal is removed from the surface of a workpiece to make it smooth. A grinding machine has a *grinding wheel* that spins at high speed against the workpiece. This wheel is made of an abrasive material similar to that on sandpaper.

Two of the main types of grinding operations are *cy-*

Electrical discharge machining (EDM) produces smooth, accurate holes in metal by means of an electric current.

WORLD BOOK illustrations by Steven Liska

High-energy rate forming (HERF) uses an explosive charge to force sheet metal into the contours of a die.

lindrical and *surface.* In cylindrical grinding, a round workpiece rotates against the grinding wheel. A type of cylindrical grinding called *centerless grinding* is widely used in mass production. It involves two rotating wheels. One wheel rubs against the workpiece and turns it while the other grinds the workpiece. In surface grinding, a flat workpiece moves back and forth against a rotating wheel. In both cylindrical grinding and surface grinding, sharp edges of abrasive particles on the grinding wheel cut tiny chips from the workpiece, producing a smooth surface texture.

In *lapping,* an abrasive paste or other substance is used to remove metal. Lapping provides an extremely smooth surface when only a small amount of metal must be removed. A lapping machine has a metal plate covered with an abrasive. *Honing* assures maximum accuracy in finishing holes to precise dimensions. In this process, an abrasive paste is applied to cylindrical parts called *heads,* which are inserted into the hole. The heads rotate while moving up and down.

Metal forming operations include forging, pressing, bending, and shearing. There are four main types of forming machines: (1) forging machines, (2) presses, (3) press brakes, and (4) shears.

Forging machines form metal by hammering and squeezing it. Some of these machines hammer hot metal into any shape. Others squeeze hot metal in a *die* (mold) under great pressure. The metal flows to every part of the die and takes the desired shape. Forging machines produce extremely tough and durable metal parts.

Presses stamp a metal sheet into a certain shape. Then they use a die to squeeze this piece of metal, called a *blank,* into the final shape. *Punch presses* punch holes in metal sheets.

Press brakes bend sheets of metal to make products. These products include hoods and roofs for automobiles and the sides of cabinets and refrigerators.

Shears cut large sheets of metal much as scissors cut sheets of paper. Machinists then work the metal into finished parts of the desired shape and size.

Advanced machine tool operations

Advanced machine tools cut extremely hard metals into complex shapes by means of electrical or chemical energy, heat, magnetism, or other forces. Advanced machine tool operations are used chiefly to make large steel dies for the manufacture of automobile parts and other parts. These methods include (1) electrical discharge machining, (2) electrochemical machining, (3) chemical machining, and (4) high-energy rate forming.

Electrical discharge machining (EDM) cuts holes in extremely hard metals, including steel alloys that cannot be cut by traditional methods. EDM produces smooth, accurate holes, some of which have extremely complex shapes. It is the most widely used advanced machining process.

The energy for cutting comes from an electric current that flows through a part called an *electrode.* Most electrodes used in EDM are made of graphite, which has a high melting point. The electrode has the shape of the hole to be made in the workpiece. The electrode and the workpiece are submerged in an *electrolyte,* a liquid that conducts current. A current is then directed between the electrode and the workpiece, producing a discharge of sparks. This discharge has the shape of the electrode. The sparks therefore erode a hole of the same shape in the workpiece.

Electrochemical machining (ECM) uses electric current to create a chemical reaction that erodes metal from a workpiece. In ECM, current flows from a positively charged workpiece to a negatively charged cutting tool. An electrolyte pumped between the workpiece and the cutting tool conducts the current between them. The workpiece takes the shape of the face of the cutting tool.

Chemical machining. In this operation, the workpiece is covered by a chemically resistant mask. The mask has holes cut in it of the shape of those to be cut in the workpiece. The workpiece is dipped into a strong chemical solution, which dissolves the metal from the workpiece sections not covered by the mask.

High-energy rate forming (HERF) involves transmitting pressure through a liquid, usually water, to force sheet metal into the contours of a die. In most cases, the pressure is created by setting off an explosive in the liquid or by discharging an electric spark in it. HERF is used chiefly to make large metal parts that have an unusual shape, such as a dish-shaped radar antenna.

Other advanced machining operations include (1) *laser cutting* and (2) *magnetic forming.* In laser cutting, machinists aim a thin beam of concentrated light at the workpiece. This light is created by a device called a *laser.* Machinists use laser beams, which produce a great amount of heat, to make small, precise cuts or holes by melting through metal or other materials. See **Laser**. In magnetic forming, an electromagnet is created when an electric current is directed through a coil. If the coil surrounds the workpiece, the electromagnetic force shapes the workpiece by pushing the metal in. If the coil is placed within the workpiece, the force pushes the metal out.

Numerical control of machine tools

Numerical control is a system of automating machine tools. In some systems, instructions are given by means of a *control tape.* This tape, which is made of paper or plastic, contains the instructions in the form of a number code. The numbers are represented on the tape by holes or by magnetized spots. The tape is fed into the machine, which has a control unit that reads the code. This process creates electric signals that correspond to the code. The signals control the direction and speed of the machine as it moves across the workpiece.

In some other machining systems, computers have replaced control tapes. A system known as *computer numerical control* has a number of machine tools, each of which is directed by its own computer. In a system called *direct numerical control,* a single computer controls more than 100 machine tools.

A more highly automated machining system, called *adaptive control,* involves the use of a *microprocessor.* A microprocessor is a tiny electronic device that performs the work of a computer. The microprocessor regulates certain variables in the machining process, such as the speed of a spindle, to make the process as efficient as possible. It also receives information from sensors that measure force, temperature, and other variables. It uses this information to operate the system at a

level that is safe for the machine tool and the workpiece.

Another automated system, called *programmable machine control (PMC),* uses common computer programming languages to control machine tools. Under PMC, machine tools can operate for long periods without manual control.

History

The basic machine tool operations developed from processes originally used with hand tools that cut and shaped wood. The first modern machine tool was invented in 1775 by John Wilkinson, an English ironmaker. Wilkinson's invention, a boring machine, enabled workers to drill precise holes in metal. A number of other machine tools, including the planer, the shaper, and the first successful screw-cutting lathe, were also invented in England during the 1800's.

In the United States, the machine tool industry began about 1800. Machine tools were used chiefly to make guns and cannons for the armed forces. In 1873, C. M. Spencer of the United States developed a completely automatic lathe. In the 1920's, machine tools began to be linked together in series for use in mass production. The number of machine tools in the United States more than doubled during World War II (1939-1945).

In the middle and late 1900's, the development of spacecraft and other aircraft resulted in advanced machining operations. The use of numerical control, machining centers, computers, and microprocessors brought new speed and efficiency to the industry.

Machinists and Aerospace Workers, International Association of, is a labor union affiliated with the American Federation of Labor and Congress of Industrial Organizations. It has local unions in the United States and its territories and in Canada. Membership in the union is open to men and women who work in the metalworking industries, on production lines, in machine shops, garages, toolrooms, and everywhere that machinery and equipment are manufactured, installed, repaired, or operated.

The union was founded in Atlanta, Georgia, in 1888 as the National Association of Machinists. It became the International Association of Machinists in 1891, when it expanded its membership to include Canadian metalworkers. The union took its present name in 1965. It is one of the largest unions in the aerospace industry, as well as one of the largest among the railroad, automobile mechanics, airlines, machine tool, and business machine industry unions. Services include a research and statistical department, a department of safety and health, and a department of community services. The union publishes a monthly newspaper, *The Machinist.* Headquarters are in Washington, D.C. For membership, see **Labor movement** (table). Critically reviewed by the International Association of Machinists and Aerospace Workers

Machu Picchu, *MAH choo PEEK choo,* is an Inca archaeological site in Peru that probably served as a royal estate. The site holds the ruins of buildings constructed in the A.D. 1400's. Machu Picchu is about 50 miles (80 kilometers) northwest of Cusco, the former Inca capital. It stands on a high ridge in a heavily forested part of the Andes Mountains.

Machu Picchu was probably used as a home for members of the Inca royal family when they were away from Cusco. It had palaces where the royalty could stay and entertain their guests. It also had houses for the farmers, weavers, and servants who lived at the site and worked for the royal family. The buildings were made of granite and had steep thatch roofs to protect residents from the frequent rains.

Construction of Machu Picchu began sometime after about 1438, when the Inca ruler Pachacuti defeated enemy tribes in the region. Scholars think Machu Picchu was abandoned shortly after the Spanish began their conquest of the Inca in 1532.

Machu Picchu's archaeological importance was first recognized in 1911, when the American explorer Hiram Bingham visited the site. Peru's government now sponsors research and reconstruction there. The site has become Peru's chief tourist attraction. Susan A. Niles

Macintosh, *MAK ihn tahsh,* **Charles** (1766-1843), a Scottish chemist and inventor, is best known as the inventor of waterproof fabrics. The *mackintosh,* a rubberized, waterproof outer garment, is named after him. Macintosh made many contributions to chemical technology. He opened a factory to manufacture alum and sal ammoniac before he was 20 years old. He also introduced into Britain the manufacture of lead and aluminum acetates and contributed to the technology of dyeing. Macintosh was born in Glasgow. John A. Heitmann

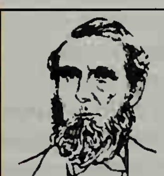
Mack, Connie (1862-1956), became one of the greatest managers in baseball history. He helped organize the American League and served as owner-manager of the Philadelphia Athletics from 1901 to 1950. Mack spent more than 60 years in baseball. He led the Athletics to nine American League pennants and five World Series championships. His sons later sold the team, and it moved to Kansas City, Missouri, in 1955 and later to Oakland, California. Mack was born in East Brookfield, Massachusetts. His real name was Cornelius Alexander McGillicuddy. Mack was elected to the National Baseball Hall of Fame in 1937. Jack Lang

Mackay, *MAK ee,* **John William** (1831-1902), was an American miner and financier. Along with another financier, James Gordon Bennett, Jr., Mackay organized the Commercial Cable Company and the Postal Telegraph Company in 1883. They laid two cables under the Atlantic Ocean and were beginning to lay one under the Pacific Ocean when Mackay died.



Mackay was born in Ireland but came to New York City with his parents as a boy. In 1851, he went to California to seek gold. Mackay made his fortune as one of the owners of the "Big Bonanza" gold and silver mine. This mine, discovered in 1873 at Virginia City, Nevada, was the richest deposit of gold and silver ore ever found. The value of a share in the mine shot up from 15 cents to $1,850. Mackay became a millionaire almost overnight. At their height, his earnings from the "Big Bonanza" were said to have reached $800,000 a month.

Alexander Mackenzie

Prime Minister of Canada
1873-1878

Macdonald
1867-1873

Mackenzie
1873-1878

Macdonald
1878-1891

Detail of a portrait by J. W. L. Forster; Parliament Buildings, Ottawa (John Evans)

Mackenzie, Alexander (1822-1892), served as prime minister of Canada from 1873 to 1878. He was the second person, and the first Liberal, to hold that office.

Mackenzie faced many national economic problems as prime minister, chiefly because he served during a worldwide depression. But he strengthened the new nation by promoting honest, democratic government and greater independence from Great Britain. He won respect for his determination, hard work, and honesty.

Mackenzie, a Scottish immigrant, had little formal education. He worked as a stonemason before entering politics, and his appearance reflected his humble background. He had the muscular body and strong hands of a laborer. A reddish beard emphasized his strong chin. Mackenzie spoke with a Scottish accent.

Early life

Childhood and education. Alexander Mackenzie was born on Jan. 28, 1822, in the village of Logierait, Scotland, about 50 miles (80 kilometers) north of Edinburgh. He was the third of the 10 children—all sons—of Alexander Mackenzie, a carpenter, and Mary Fleming Mackenzie. When Alexander was 10, he began to herd sheep to help support the family. His father, whose health had been poor, died three years later. Alexander then left school to train as a stonemason.

Alexander continued to read on his own and, in time, gave himself a good education. He finished his training as a stonemason when he was about 20 and got a job on a railroad construction project near Irvine, Scotland.

Important dates in Mackenzie's life

1822 (Jan. 28) Born in Logierait, Scotland.
1842 (May) Settled in Kingston, Upper Canada.
1845 (March 28) Married Helen Neil.
1852 (Jan. 4) Helen Neil Mackenzie died.
1853 (June 17) Married Jane Sym.
1861 Elected to the Legislative Assembly of the Province of Canada.
1873 (Nov. 7) Became prime minister of Canada.
1878 (Oct. 17) Resigned as prime minister.
1892 (April 17) Died in Toronto.

Emigration to Canada. In Irvine, Mackenzie fell in love with Helen Neil, the daughter of a stonemason. Her family emigrated to Canada in 1842, and Mackenzie went along. They settled in Kingston, the capital of the Province of Canada. The province consisted of Upper Canada (present-day Ontario) and Lower Canada (present-day Quebec). Mackenzie became a builder and contractor, and he and Helen were married in 1845.

In 1847, the young couple moved to what was then the Far West of Canada. They settled in Sarnia, Upper Canada. Helen and Alexander had three children, but only one, their daughter Mary, survived. Helen died in 1852. The next year, Mackenzie married Jane Sym, whose father was a Sarnia farmer.

Entry into political life

Member of the Reformers. Soon after settling in Canada, Mackenzie joined the Reform Party, a liberal political party. He became a follower of George Brown, a Reform leader and the publisher of the *Globe* in Toronto. In 1851, Mackenzie helped Brown win election to the Legislative Assembly of the Province of Canada.

Brown in time became the leader of the Reform Party. From 1852 to 1854, Mackenzie edited the *Lambton Shield,* a newspaper that supported the Reformers. In 1861, he won election to the Legislative Assembly from Lambton County, Upper Canada.

In 1867, several British colonies in North America united and formed the Dominion of Canada. Sir John A. Macdonald, the leader of the Conservative Party, became the first prime minister after Confederation. The Dominion's first elections took place in 1867. Mackenzie won election to the House of Commons, but Brown was defeated. Mackenzie then replaced Brown as head of the Reform Party. He united Reformers and liberals throughout Canada into a new Liberal Party.

Leader of the Opposition. The Conservatives won a majority in Parliament in the 1872 elections, and Macdonald remained prime minister. Mackenzie had unofficially led the Liberal Party since Confederation. In 1873, the party appointed him to the official position of *leader of the opposition.* This office is held by the head of the second largest party in the House.

Later in 1873, a scandal disgraced the Macdonald administration. Two financial groups had competed for a government contract to build the Canadian Pacific Railway between eastern Canada and the Pacific Coast. The government gave the contract to the group headed by Sir Hugh Allan, the owner of a shipping line. But then it was learned that Allan had contributed $300,000 to the Conservative election campaign of 1872. Mackenzie and other Liberals attacked the Macdonald government about the so-called Pacific Scandal, and Macdonald resigned. On Nov. 7, 1873, Mackenzie became Canada's second prime minister.

Prime minister

Reforms. Mackenzie called for new elections to be held in January 1874. The Liberal Party won a large majority in the House. Under Mackenzie's leadership, Parliament took many steps to promote honest, democratic government. For example, it passed laws to prevent dishonest election practices and allow more citizens to vote. It also introduced the secret ballot, which was first used in 1878.

To guarantee honesty in his administration, Mackenzie himself took charge of the Department of Public Works. This department controlled the construction of such projects as railroads and public buildings. It spent more than any other government department—and thus offered the greatest possibilities for dishonesty.

Strengthening the new nation. Mackenzie's administration strengthened Canadian independence by dealing directly with the United States. Previously, British diplomats had met with representatives of other nations in Canada's behalf. Mackenzie also established the Royal Military College in 1874 and the Supreme Court of Canada in 1875. These institutions enabled Canada to handle more of its own military and legal affairs.

The Pacific Railway dispute occurred when the government ran short of time and money in building the Canadian Pacific Railway. In 1871, British Columbia had become part of Canada on the condition that the transcontinental railroad be started in 2 years and completed within 10 years. Mackenzie asked for more time, and the province threatened to secede from Canada.

The dispute between British Columbia and the Canadian government led to one of Mackenzie's most important achievements as prime minister. At that time, the British statesman Frederick T. Blackwood, Marquess of Dufferin and Ava, was governor general—the British monarch's representative in Canada. Lord Dufferin proposed that an official in London settle the dispute. However, Mackenzie protested against such an arrangement. He insisted that the governor general respect decisions that were made by Canadian officials. As a result, the British government revised the powers of the governor general and allowed Canada to handle its own internal affairs. The Canadian Pacific Railway was completed in 1885.

Economic difficulties and defeat. Mackenzie served as prime minister during a worldwide depression. With the Canadian economy in a slump, taxes did not provide enough income to pay expenses. Mackenzie, following the economic beliefs of his time, reduced government spending and increased taxes. But these steps failed to lift Canada out of the depression.

Hoping to win a vote of confidence, Mackenzie called for new elections to be held in September 1878. In the election campaign, the Conservatives attacked Mackenzie's leadership during the depression. Macdonald called for a "National Policy" that included tariff protection for Canadian industries. This idea appealed to many voters because of the nation's economic difficulties. The Conservatives won a large majority in Parliament, and Macdonald replaced Mackenzie as prime minister on Oct. 17, 1878.

Later years

Mackenzie was reelected to the House of Commons from Lambton County and again became leader of the opposition. But the strain of office had damaged his health, and he resigned as opposition leader in 1880. Mackenzie won reelection to the House three more times. He was still a member of Parliament when he died in Toronto on April 17, 1892. Dale C. Thomson

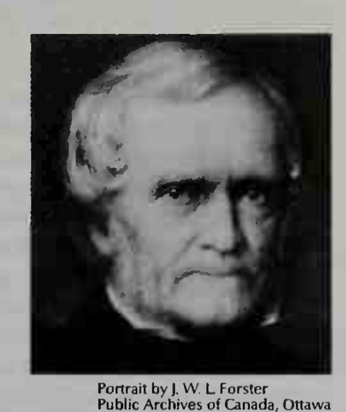
Gough, Barry. *First Across the Continent.* Univ. of Okla. Pr., 1997.
Thomson, Dale C. *Alexander Mackenzie.* Macmillan, 1960. A standard biography.
Xydes, Georgia. *Alexander Mackenzie and the Explorers of Canada.* Chelsea Hse., 1992. Younger readers.

Mackenzie, Sir Alexander (1764-1820), was a Canadian explorer, trader, and businessman. He was the first white man to reach the Mackenzie River and to cross the northern part of North America to the Pacific Ocean.

In 1789, Mackenzie left Fort Chipewyan on Lake Athabasca with a small party of Canadians and Indian guides. He pushed his way north to Great Slave Lake and then followed the river that now bears his name. It took him to the Arctic Ocean. He had hoped the river would lead him to the Pacific Ocean.

Three years later, Mackenzie started on an expedition to the west coast. He followed the Peace River, crossed the Rocky Mountains, and reached the Pacific Ocean in 1793. This trip convinced him that a search for a Northwest Passage to the Orient would prove useless. How-

ever, he promoted the idea of carrying on trade across the Pacific Ocean.



He wrote *Voyages on the River Saint Lawrence and Through the Continent of North America to the Frozen and Pacific Oceans in the Years 1789 and 1793* (1801). This book contains much valuable information on Indian tribes and Canadian history.

Mackenzie was born in Stornoway, on the Scottish island of Lewis with Harris. In 1778, he went to Canada. He later became a partner in the North West Company, a leading Canadian fur-trading company. Mackenzie made a fortune as a fur trader. He spent his last years in Scotland. Barry M. Gough

Mackenzie, Roderick (1760?-1844), was a Canadian frontiersman and fur trader. He accompanied his cousin, Sir Alexander Mackenzie, on a trip to western Canada in 1786. He commanded Fort Chipewyan in northeastern Alberta from 1789 to 1793. Mackenzie was a capable administrator rather than a trailblazer. He returned to eastern Canada in 1797, and became a partner in the North West Company in 1799. Later, he served in the Legislative Council of Lower Canada. Mackenzie was born in Scotland. John Elgin Foster

Mackenzie, William Lyon (1795-1861), was a Canadian political leader and journalist. In the 1830's, he led a revolt against British rule in the North American colony of Upper Canada.

Mackenzie was born in Dundee, Scotland. He moved to Canada in 1820. In 1824, he founded the *Colonial Advocate,* a newspaper. In 1828, Mackenzie won election to the Legislative Assembly of Upper Canada as a member of the Reform Party. He argued for greater local self-government under British rule. In 1834, he became the first mayor of Toronto.

Portrait by J. W. L. Forster
Public Archives of Canada, Ottawa
William L. Mackenzie

Mackenzie and the Reform Party were defeated in elections in 1836, and Mackenzie soon began to doubt the possibility of achieving peaceful reform. In 1837, he led a revolt to seek independence for Upper Canada from Britain. But local militia easily defeated the few hundred rebels. Mackenzie's revolt was one of the two unsuccessful Rebellions of 1837. In the other rebellion, Canadians in the colony of Lower Canada also fought against British rule.

Mackenzie escaped to the United States. He established a temporary government on Navy Island in the Niagara River. U.S. authorities soon arrested him for breaking the neutrality laws. He was tried and imprisoned in 1839 but pardoned in 1840.

Mackenzie worked as a journalist in New York until 1849, when he was allowed to return to Canada. In 1851, he won election to the Legislative Assembly of the Province of Canada, a colony formed by a union of Upper and Lower Canada. J. M. Bumsted

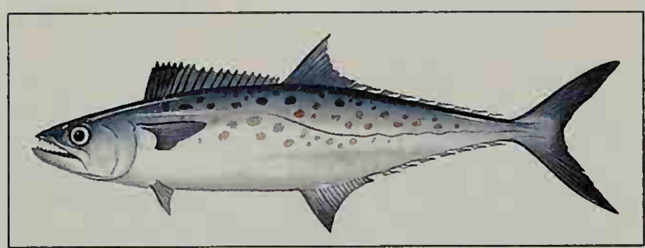
WORLD BOOK map

Location of the Mackenzie River

Mackenzie River, in the Northwest Territories, is the longest river in Canada. It flows north and west for about 1,071 miles (1,724 kilometers) from Great Slave Lake to the Beaufort Sea. Much of the river is more than 1 mile (1.6 kilometers) wide. Water flows into the Mackenzie from many tributaries, including the Liard, Great Bear, Arctic Red, and Peel rivers. Water also enters from Great Slave Lake. It reaches the lake through the Slave River, which collects water from the Peace and Athabasca rivers. The Mackenzie was named for the Canadian explorer Sir Alexander Mackenzie (see **Mackenzie, Sir Alexander**).



All the rivers mentioned above are part of the *Mackenzie River System,* Canada's largest river system. This vast system drains water from about 682,000 square miles (1,766,000 square kilometers). Its most distant water source is high in Alberta's Rocky Mountains, 2,635 miles (4,241 kilometers) from the Arctic mouth of the Mackenzie. In North America, only the Mississippi-Missouri system in the United States is longer than the Mackenzie system.

Barges carry cargo over much of the Mackenzie River system. The Mackenzie River basin is rich in natural resources. The Peace River area of Alberta and British Columbia includes abundant farmland. The area also has petroleum and natural gas deposits and water for hydroelectric power.

In the northern part of the Mackenzie basin, the delta at the mouth of the river is a muskrat-trapping area. Hundreds of thousands of ducks, geese, swans, and cranes migrate to nesting grounds in the Mackenzie delta annually. The delta has little agriculture, but the region has important deposits of petroleum, radium, and uranium.
G. Peter Kershaw

Mackerel, *MAK uhr uhl* or *MAK ruhl,* is the name of a number of valuable food fish that live in coastal areas of the Atlantic, Pacific, and Indian oceans. Mackerels have long, tapered bodies and forked tails. They swim in schools and are constantly on the move. Four common species of mackerel are the *Atlantic, chub, king,* and *Spanish.*

The Atlantic mackerel, also called the *common mackerel,* lives in temperate parts of the North Atlantic

WORLD BOOK illustration by Colin Newman, Linden Artists Ltd.

The mackerel has blue-green skin and a forked tail.

Ocean. On the North American side of the Atlantic, this fish is found from North Carolina to Newfoundland. On the European side, it ranges from the Mediterranean Sea to Norway. Most Atlantic mackerel measure from 10 to 18 inches (25 to 46 centimeters) long. The fish *spawn* (reproduce) in the spring and summer near shore. Females can produce up to 200,000 eggs in a season.

The king and Spanish mackerels live mostly in tropical parts of the Atlantic. The king mackerel is found from Cape Cod to Rio de Janeiro, Brazil, and the Spanish mackerel ranges from Cape Cod to the Yucatán Peninsula in Mexico. Both species inhabit waters north of Florida only during the summer. They eat large quantities of small fish and smaller amounts of shrimp and squid. The largest king mackerels grow more than 5 $\frac{1}{2}$ feet (170 centimeters) long. Spanish mackerels can grow more than 2 $\frac{1}{2}$ feet (76 centimeters) long.

The chub mackerel, also called the *Pacific mackerel,* has a wide geographic distribution. Along the Pacific Coast of North America, chub mackerels range from southeastern Alaska to Baja California. Along the Atlantic Coast, they are found from Cape Cod to Cuba. Chub mackerels that live in the Atlantic have spots or wavy broken lines on their bellies. Chub mackerels grow to about 20 inches (51 centimeters) long. Gary T. Sakagawa

Scientific classification. Mackerels belong to the family Scombridae. The scientific name for the Atlantic mackerel is *Scomber scombrus.* The chub mackerel is *S. japonicus.* The king mackerel is *Scomberomorous cavella,* and the Spanish mackerel is *Scomberomorous maculatus.*

Mackinac, *MAK uh NAW* or *MAK uh NAK,* **Straits of,** is an important link in the water route between Lake Michigan and the Atlantic Ocean. The straits connect Lake Michigan and Lake Huron. They are at the northern end of the Lower Peninsula of Michigan (see **Michigan** [physical map]). Mackinac Island lies in the straits. The straits are about 40 miles (64 kilometers) long and about 5 miles (8 kilometers) wide at the narrowest point. The Mackinac Bridge across the straits is one of the world's longest suspension bridges. Its main span is 3,800 feet (1,160 meters) long. The bridge links Mackinaw City in the Lower Peninsula with the city of St. Ignace in the Upper Peninsula. Richard A. Santer

Mackinac Island, *MAK uh NAW* or *MAK uh NAK,* is a north Michigan island summer resort in the Straits of Mackinac (see **Michigan** [political map]). It covers an area of about 4 square miles (10 square kilometers) and has a year-round population of about 500 The Chippewa Indians called the island *Michilimackinac,* which is usually defined as *Great Spirits* or *Great Turtle.* No passenger cars are permitted on Mackinac. Ferries link the island with the mainland. In the winter, when an "ice bridge" forms, snowmobiles deliver supplies from the mainland. The world's longest freshwater yachting event is the Chicago-to-Mackinac Island race, held each July.

In 1671, Father Jacques Marquette established a mission at nearby Point St. Ignace. The French built forts at St. Ignace and Mackinaw City, on the Michigan mainland. In 1761, the French surrendered the area to the British. The British built Fort Mackinac on the island in 1780. In 1796, the United States gained the island. The British captured it during the War of 1812 but returned it to the United States in 1815. The island became the headquarters of John Jacob Astor's American Fur Company. After the fort was abandoned in 1894, the federal

Dwight Ellefsen, Shostal

Mackinac Island is an important summer resort in the Straits of Mackinac in northern Michigan. The island's fine harbor is a popular destination for owners of yachts and sailboats.

government transferred much of the island to the state of Michigan. Most of this land became Mackinac Island State Park. The island and its surrounding area have become a center of archaeological research and historical reconstruction. Peter Gavrilovich

See also **Henry, Alexander.**

MacLeish, *mak LEESH* or *muh KLEESH,* **Archibald** (1892-1982), was an American poet, dramatist, and critic. He also served as librarian of Congress from 1939 to 1944 and assistant secretary of state in 1944 and 1945.

MacLeish's early work is lyrical and thoughtful, using free verse and other technical methods of such older poets as Ezra Pound and T. S. Eliot. *Conquistador* (1932) is a strong, individual achievement, describing in epic terms the Spanish exploration of the New World. The work gained MacLeish the first of his three Pulitzer Prizes. With social unrest in America and the rise of fascism abroad, MacLeish turned to more direct expression of the issues of his day. He particularly explored these issues in *Public Speech* (1936) and his two radio dramas, *The Fall of the City* (1937) and *Air Raid* (1938).

MacLeish's later work became less topical and more philosophic in tone. His verse drama *J.B.* raises the eternal problem of humanity's suffering, treating the Biblical story of Job in terms of modern American life. The play won the 1959 Pulitzer Prize for drama. His *Collected Poems, 1917-1952* won the 1953 Pulitzer Prize.

MacLeish's most mature reflections on the value of poetry as a means of knowledge are developed in *Po-*

etry and Experience (1961). He concludes, "To face the truth of the passing away of the world, and make song of it, make beauty of it, is not to solve the riddle of our mortal lives but perhaps to accomplish something more."

MacLeish was born in Glencoe, Illinois. He received a law degree from Harvard, where he graduated first in his class. He practiced law from 1920 to 1923, when he decided to devote himself to literature. MacLeish lived in Europe from 1923 to 1928. He was professor of rhetoric and oratory at Harvard from 1949 to 1962.

Bonnie Costello

MacLennan, *muh KLEHN uhn,* **Hugh** (1907-1990), was a Canadian author known for his novels about historic events and public issues in Canada. His strengths are his ability to convey the texture and tensions of society and his descriptions of places.

MacLennan based his first novel, *Barometer Rising* (1941), on an explosion that destroyed much of the city of Halifax, Nova Scotia, in 1917. *Two Solitudes* (1945) and *Return of the Sphinx* (1967) deal with conflicts between English Canadians and French Canadians. *Each Man's Son* (1951) is set in his native Cape Breton Island. *The Watch That Ends the Night* (1959) describes how a group of characters were affected by the Great Depression of the 1930's and by World War II (1939-1945).

MacLennan wrote many essays, including analyses of Canadian culture and sensitive descriptions of landscape. His collections of essays include *Cross Country* (1949), *Rivers of Canada* (1974), and *The Other Side of Hugh MacLennan* (1978). John Hugh MacLennan was born in Glace Bay, Nova Scotia. Laurie R. Ricou

MacMillan, Donald Baxter (1874-1970), an American polar explorer, added much to our knowledge of Greenland and the Canadian Arctic. He found coal deposits 9 degrees from the North Pole. These deposits contained the remains of 36 kinds of trees, showing that the climate there had once been milder.

MacMillan's 1924 Arctic expedition used radio extensively. His 1925 expedition was one of the first to use airplanes in the Far North. His men made many special aerial photographs. MacMillan received the Special Congressional Medal for surveying and charting Greenland and the Canadian Arctic for the U.S. Army during World War II (1939-1945). In 1957, at the age of 82, MacMillan went on his 31st trip to the Arctic. He wrote several books about his experiences, including *Four Years in the White North* (1918), *Etah and Beyond* (1927), and *How Peary Reached the Pole* (1932).

MacMillan was born in Provincetown, Massachusetts. He studied at Bowdoin College and at Harvard University. MacMillan taught school until 1908, when he made his first polar expedition as assistant to Commander Robert Peary. On his voyages to the Arctic, MacMillan helped to train many younger explorers, including Richard Evelyn Byrd. William Barr

Macmillan, Harold (1894-1986), served as prime minister of the United Kingdom from 1957 to 1963. Macmillan succeeded Sir Anthony Eden in that office.

Macmillan was elected to the House of Commons in 1924 as a Conservative. In the 1930's, he became more progressive. He criticized British Prime Minister Neville Chamberlain and the Munich settlement with Nazi Germany in 1938 (see **Munich Agreement**). He also urged action to combat Britain's economic depression.

From 1942 to 1945, Macmillan served in Prime Minister Winston Churchill's World War II government as British resident minister at Allied headquarters in northwest Africa. Macmillan served as Churchill's minister of housing and local government from 1951 to 1954 and as minister of defense in 1954. He became foreign secretary under Eden in April 1955 and chancellor of the exchequer, the United Kingdom's chief financial officer, in December 1955.

Maurice Harold Macmillan was born in London. His grandfather founded the Macmillan publishing company. Harold Macmillan attended Eton College and Oxford University. He fought and was wounded in World War I (1914-1918). In 1984, he was granted the title Earl of Stockton. Keith Robbins

Macon, *MAY kuhn* (pop. 97,255; met. area pop. 322,549), is a center of manufacturing and trade and one of the largest cities in Georgia. Macon lies on the Ocmulgee River in central Georgia and is called the *Heart of Georgia.* Its location helped Macon become a convention center for state and regional meetings. For location, see **Georgia** (political map).

Macon is the home of the Georgia Academy for the Blind, Macon State College, Mercer University, and Wesleyan College. The Cherry Blossom Festival each March celebrates the city's more than 250,000 Japanese cherry trees. Macon's Hay House, a historic mansion, and Ocmulgee National Monument, the site of prehistoric Indian mounds, draw many visitors. Other attractions include the birthplace of poet Sidney Lanier, the Georgia Music Hall of Fame, the Georgia Sports Hall of Fame, and the city's six national historic districts.

Macon serves as the trading center for the famous peach region of Georgia and is a large poultry processor. One of the world's largest kaolin deposits lies near Macon. Macon's most important industries are the manufacture of food products, textiles, and tobacco products. Other products made in the city include aircraft parts, chemicals, furniture, paper products, and zippers. Two railroads provide freight service for Macon, and two interstate highways intersect there. Macon is a regional health center with six hospitals. The Macon area also has many companies in the aerospace industry.

Creek Indians first settled the Macon area. Thomas Jefferson established Fort Hawkins there in 1806. The city was chartered in 1823 and named for Nathaniel Macon, a North Carolina congressman. During the 1840's and 1850's, Macon became an important railroad center. Confederates repulsed a Union attack on Macon in 1864, during the American Civil War.

Macon has a mayor-council form of government. It is the county seat of Bibb County. Bill Boyd

Macphail, *muhk FAYL,* **Agnes Campbell** (1890-1954), was the first woman ever elected to the Canadian House of Commons. She served in the federal Parliament from 1921 to 1940, and in the Ontario Legislature from 1943 to 1945 and from 1948 to 1951. She represented Canada in the Assembly of the League of Nations. Macphail was elected to Parliament as a United Farmers of Ontario candidate. She later supported the Co-operative Commonwealth Federation. She was born in Grey County, Ontario, and taught in Canadian schools before entering politics. David Jay Bercuson

Macramé by Mary Walker Phillips; American Craft Council

A macramé wallhanging is made by knotting together different colored yarn and string into decorative patterns.

Macramé, *MAK ruh may,* is the art of creating practical and decorative articles by knotting cord, rope, or string. It can be used to make clothing and such accessories as belts and purses, as well as sculptures, wallhangings, and other ornamental items.

Many individual cords are knotted together to make a macramé article. The two basic knots used are the clove hitch and the square knot (see **Knots, hitches, and splices** [illustrations]). These knots may be combined with each other or with different knots in an unlimited number of arrangements. Beads, bells, feathers, and other small objects can be tied into the work for variety.

Arabian weavers probably developed knotting in the 1200's. The word *macramé* comes from an Arabic or Turkish word for *towel,* or *napkin.* In the 1970's, macramé had a revival as a handicraft. Fiber artists and craftworkers developed new uses for the finished fabrics. Macramé was often combined with basketmaking, embroidery, and knitting. Dona Z. Meilach

Macready, *muhk REE dee,* **William Charles** (1793-1873), was a famous English tragic actor. He encouraged the dramatic works of poets Lord Byron and Robert Browning and restored integrity and accuracy to the staging of William Shakespeare's plays. Macready's acting was restrained, dignified, and intellectual. A rivalry with American actor Edwin Forrest led to a riot in 1849 at the Astor Place Opera House in New York City, where Macready was performing in *Macbeth.* In the riot, 31 people were killed and about 150 were injured.

Macready was born in London. He made his stage debut in London in 1816. Macready's diaries are an important source of theater history. J. P. Wearing

Mad cow disease is a brain disease in cattle that causes odd behavior, difficulty walking, and then death. It is also called *bovine spongiform encephalopathy (BOH vyn SPUHN jih fawrm ehn sehf uh LAHP uh thee).* Mad cow disease and related *prion diseases* produce damaged brain tissue that looks spongelike under a microscope. Mad cow disease was first identified in 1986 in the United Kingdom, where sheep suffer from a similar disease called *scrapie.* Scientists think mad cow disease arose when cattle were fed supplements containing brains and spinal cords from scrapie-infected sheep. In 1988, the British government banned use of cattle and sheep by-products to feed other cattle and sheep.

In 1996, British experts announced that beef from "mad cows" might be linked to a new form of Creutzfeldt-Jakob disease (CJD), a rare prion disease in human beings. Scientists believe the new variant, termed vCJD, can be transmitted to people by eating infected beef. Since 1996, hundreds of thousands of cattle have been destroyed in Britain to prevent further contamination of the food supply. Most nations banned beef imports from Britain after 1996. But in 2000, cases of vCJD were found in France, Germany, and Spain. Stanley B. Prusiner

Madagascar is an African country with one big island and many tiny ones. It is in the Indian Ocean, about 240 miles (386 kilometers) southeast of the African mainland. The large island, also called Madagascar, is the world's fourth largest island. Only Greenland, New Guinea, and Borneo are larger islands. Most of the people are farmers or herders of mixed black African and Indonesian descent. Antananarivo is the capital and largest city.

Madagascar was a favorite base for sea pirates in the 1600's and 1700's, including the famous Captain William Kidd. Later, it became a haven for slave traders. In the early 1800's, most of Madagascar became part of the local Merina kingdom. The Merina kingdom fell to the French in 1896, and all of Madagascar became a French colony. Madagascar gained independence from France in 1960. It was called the Malagasy Republic until 1975, when its name was changed to Madagascar. Its official name is the Republic of Madagascar.

Government. The head of state is the president, who is elected to a term of five years. The president appoints a prime minister and, on the recommendation of the prime minister, the other members of the Council of Ministers. The 150 members of the National Assembly, the lower house of the nation's legislature, are elected by the people to five-year terms. Sixty members of the 90-seat Senate are chosen by an *electoral college* of mainly local officials. The president appoints the other 30. Senate members serve six-year terms.

People. The people of Madagascar are called the Malagasy. The population is made up of several ethnic groups of mixed Indonesian and black African descent. Ethnic groups of the central and south-central highlands tend to resemble Indonesians. Many raise rice in irrigated fields just as do farmers in Indonesia. The coastal groups more closely resemble black Africans. Many herd cattle as do peoples of eastern Africa. Political rivalries exist between the coastal and the highland peoples, but the two groups share control of the government.

Malagasy is the language spoken throughout the nation. It resembles Malay and Indonesian. French and Malagasy are the official languages. About half the people are Christians. About a tenth are Muslims. The rest—especially those living along the coasts—practice local African religions. They worship ancestors and spirits.

The Malagasy have great respect for their ancestors. They devote much effort to caring for their graveyards. Many tombs look like painted houses. Other tombs have beautifully carved wooden ornaments on top. The Malagasy who practice local African religions perform cattle sacrifices and other ceremonies at family tombs.

Many people of Madagascar wear European-style

Alain Le Garsmeur, Panos Pictures

Antananarivo, Madagascar, is the country's capital and largest city. Narrow, hilly streets lead people to the city's downtown area, which has many modern buildings.

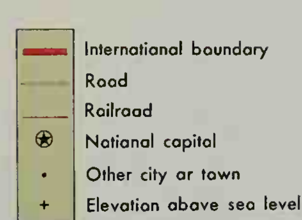
clothing. The country's markets sell many American T-shirts and blue jeans. But each region in Madagascar has a distinctive straw hat that the people wear on special occasions. The people who live in isolated southern regions often wear little clothing. Most houses in the country are built of brick, and many are several stories high. They have tile or thatched roofs. The people eat rice, vegetables, fruit, and sometimes meat and fish.

Most of Madagascar's adults can read and write. For the country's literacy rate, see **Literacy** (table: Literacy rates for selected countries). Almost all the children attend primary schools, but only about a fifth of the children attend high school. The University of Madagascar's main campus is in Antananarivo.

Land. Northern Madagascar has fertile soil. Mountains separate it from the rest of the island. Western Madagascar has wide plains, some fertile river valleys, and a fairly sheltered coast. A narrow plain lies along the east coast. Some coastal shipping uses the Ampanalana Canal, which runs along the east coast between Mahavelona and Farafangana. The climate is warm and humid on the coast. The southern end of the island is mainly desert and has a hot, dry climate.

Central Madagascar consists of highlands with altitudes of 2,000 to 4,000 feet (610 to 1,200 meters) and some higher mountains. The region is *deforested* (cleared of trees) and the soil is *eroded* (worn away), but it has the densest population. In some places, farmers cut down the trees to make room for crops. Elsewhere, people turned forested land into pasture for their cattle, most of which are zebus. Many people in Madagascar measure their wealth by the number of cattle they own. In fact, Madagascar has nearly as many zebus as it has people. But overgrazing by livestock has caused much of the country's soil erosion. The highlands are cool, and temperatures at Antananarivo generally range from 48 to 81 °F (9 to 27 °C).

Facts in brief



Capital: Antananarivo.
Official languages: Malagasy and French.
Area: 226,658 sq. mi. (587,041 km²). *Greatest distances*—north-south, 980 mi. (1,580 km); east-west, 360 mi. (579 km). *Coastline*—2,600 mi. (4,180 km).
Population: *Estimated 2002 population*—16,811,000; density, 74 persons per sq. mi. (29 per km²); distribution, 78 percent rural, 22 percent urban. *1993 census*—12,092,157.
Chief products: *Agriculture*—cassava, cloves, coffee, livestock, rice, sugar cane, vanilla. *Mining*—bauxite, chromite, coal, graphite. *Manufacturing*—food processing.
Flag: A white vertical stripe appears at the left, with a red horizontal stripe over a green one at the right. White is for purity, red for sovereignty, and green for hope. See **Flag** (picture: Flags of Africa).
National anthem: "Ry Tanindrazanay Malala O" ("Our Beloved Country").
Money: *Basic unit*—franc.

Gerald Cubitt, Bruce Coleman Ltd.

In southern Madagascar, people often use cattle like these zebus to transport goods and do heavy farm work.

Madagascar

WORLD BOOK maps

Animal and plant life. Most kinds of animals and plants in Madagascar do not exist anywhere else in the world, except on the nearby Comoros Islands. The best-known wild animals in Madagascar are the lemurs. The country has about 20 species of these relatives of monkeys, most of which live in trees. Madagascar's other animals include the tenrecs. Some of these small mammals resemble hedgehogs, and some resemble shrews. Other native animals include the Malagasy mongoose and local species of chameleons, tortoises, and moths and butterflies. The amazing elephant bird, which probably became extinct about 1,000 years ago, lived only in Madagascar. The bird, which could not fly, grew up to 10 feet (3 meters) tall and weighed about 1,000 pounds (450 kilograms). See **Lemur; Tenrec; Elephant bird.**

Madagascar's forests, which formerly covered most of the island, now survive mostly near the coast. Nevertheless, many unique plants still grow on the island. About 1,000 orchid species live in the wet forests of the east. In the drier interior, grass has replaced most trees. But the region still has several varieties of baobab trees, which store water in their thick, bulging trunks. Wildlife preserves help protect some wild animals and plants.

Economy. Madagascar has a developing economy. About three-fourths of the people are farmers and herders. Rice is their chief food crop. Bananas, cassava, and sweet potatoes are also grown. Cattle are the country's most important livestock. Coffee is the chief export. Madagascar is the world's greatest producer of natural vanilla and cloves. Other exports include sugar and *sisal,* which is used to make binding twine. Bauxite, chromite, coal, and graphite are mined in Madagascar.

Most of the country's few industries process hides, meat, sisal, and sugar for export. In 1989, Madagascar's government began a policy of encouraging foreign companies to build industrial plants in the country. Most foreign trade is with France. The United States buys coffee, cloves, and vanilla from Madagascar.

Roads, most of which are unpaved, link the chief cities and towns of Madagascar. But many roads have bad ruts and are impassable during the rainy season. Air Madagascar provides air service between the major cities and makes international flights from Antananarivo. Toamasina and Mahajanga are the leading seaports.

Several daily newspapers, representing a variety of political opinions, are published in Madagascar. The government sometimes restricts what they may print.

History. Immigrants from Indonesia moved to the island in successive waves starting long before the time of Christ and lasting until the A.D. 1400's. They settled in the central highlands. Immigrants from Africa and the Arabian Peninsula settled on the coasts. Many king-

Lemurs are the best-known wild animals of Madagascar. They are relatives of monkeys. Like much of the country's wildlife, lemurs live only on Madagascar and the nearby Comoros Islands.

doms developed, but in the early 1800's the Merina kingdom gained control of most of the island.

Radama I, who became king in 1810, outlawed a foreign slave trade that had developed in Madagascar. However, he kept many local people in domestic slavery. The king and his successors welcomed English and French traders and missionaries. The missionaries opened churches and schools, but Merina rulers allowed only the Merina people to attend the schools. In the 1840's, Queen Ranavalona I tried to end European influence and expelled Europeans from the island. Europeans returned after she died in 1861. The French expanded their political influence in Madagascar after 1869. The French forces gained control, and France made all of Madagascar a French colony in 1896.

During World War I (1914-1918), Merina leaders began to demand independence. In 1945, France gave the colony's people some control of financial matters and the right to elect an assembly. It also allowed them to elect representatives to the French Parliament. But this did not satisfy the people. An armed revolt that lasted almost two years broke out in 1947.

Madagascar became a self-governing state in the French Community in 1958. It gained independence in 1960. French influence remained strong in the country, which was called the Malagasy Republic. Philibert Tsiranana was elected the country's first president in 1959. He was reelected president in 1965 and 1972.

In May 1972, demonstrations caused Tsiranana to resign. Army officers then took control of the government. In 1975, Didier Ratsiraka became the fourth in a series of military rulers to head the government. Under Ratsiraka and the earlier military leaders, the government took control of important parts of the country's economic activity, including many businesses owned by the French and other foreigners. In late 1975, the country changed its name from Malagasy Republic to Madagascar.

A presidential election was held in 1982, and the people elected Ratsiraka president. He was reelected in 1989. In 1991, a coalition of parties opposed to Ratsiraka called for his resignation. In 1991, Ratsiraka allowed Albert Zafy to take charge of a transitional government. In 1993, the people elected Zafy president. But in October 1996, Zafy resigned after he was impeached by the National Assembly on charges that he had engaged in unconstitutional acts. Ratsiraka was reelected president in a special election held in December 1996.

In December 2001, Ratsiraka faced Marc Ravalomanana in a presidential election. Neither man received a majority of votes. Ravalomanana claimed the election was rigged against him. In February 2002, he declared himself president and formed a government that took over Antananarivo. Ratsiraka moved his government to Toamasina. Clashes between supporters of the two men became violent. In April, the High Constitutional Court declared that Ravalomanana had won the election. Ratsiraka rejected the ruling. Ravalomanana kept control of the capital and extended control over other areas. But some areas remained loyal to Ratsiraka. Bruce Fetter

Madder is a plant that was once commonly grown in Europe and Asia for use in making dyes. The madder has rough, prickly leaves and small greenish-yellow flowers. The fruit is black. The roots of the madder produce coloring extracts, such as alizarin and purpurin, that manufacturers can use to make dyes. These extracts are treated with a chemical solution to produce colors ranging from pink and red to yellow, purple, and brown. A madder that grows in the eastern Mediterranean region produces a dye called *Turkey-red.* People in ancient Egypt used Turkey-red dye for burial wrappings. Dyes made from madder have largely been replaced by synthetic dyes. Howard L. Needles

Scientific classification. Madder belongs to the family Rubiaceae. It is *Rubia tinctorum.*

Maddux, Greg (1966-), became the first pitcher in baseball history to win the Cy Young Award four consecutive seasons. Since 1967, the award has been given each season to the best pitcher in each of the two major leagues. Maddux plays in the National League. He won the award for the 1992, 1993, 1994, and 1995 seasons. He also had the lowest earned run average in major league baseball for the 1993, 1994, and 1995 seasons. He is a right-handed pitcher known for his ability to change the speed of his pitches and to pitch with excellent control.

In 1995, he walked less than one batter for every nine innings he pitched. Maddux also won 12 consecutive Gold Glove awards, from 1990 through 2001, as the National League's best-fielding pitcher. He holds the major league career record for most putouts by a pitcher.

Gregory Alan Maddux was born on April 14, 1966, in San Angelo, Texas. He made his major league pitching debut with the Chicago Cubs in 1986. He pitched for the Cubs through 1992, when he became a free agent. He then signed with the Atlanta Braves. Dave Nightingale

Madeira Islands, *muh DEER uh,* are a group of islands that belong to Portugal. The islands, of volcanic origin, lie in the Atlantic Ocean off the northwest coast of Africa (see **Atlantic Ocean** [map]). The islands cover 307 square miles (794 square kilometers). Most of the about 264,000 residents live on Madeira, the larger of the two inhabited islands. The other inhabited island is Porto Santo. About 5,000 people live there. The Desertas and Selvagens are groups of tiny, uninhabited isles.

The island of Madeira, largest and most important of the group, is a great ocean mountain range rising to a height of 6,104 feet (1,860 meters) above sea level in the Pico Ruivo. Madeira is known as the *Rock Garden of the Atlantic* because its settlements and farms rise in terraces, covered with exotic flowers and trees. There are lush growths of orchids, bougainvillea, bignonia, hibiscus, camellias, hydrangeas, wisteria, and jacaranda. Trees include the mimosa, eucalyptus, Brazilian araucaria, Indian fig, West Indies coral, and Japanese camphor, bamboo, laurel, and palm.

Chief crops include sugar cane, corn, vegetables, bananas, oranges, mangoes, pomegranates, and the grapes that have made Madeira famous for wine.

Wine production is the principal industry of Madeira. Next in importance are the making of willow wicker furniture and baskets, and embroidering. Most women embroider at home. Fishing also contributes to the economy. Britons handle much of Madeira's trade.

Funchal is the capital of the Madeira Islands. It is also the largest city, main seaport, and chief resort center of the group. Funchal has ship connections with Lisbon, Portugal, and English ports, and air links with European and North African cities. See **Funchal.**

The harbor of Funchal, Madeira, makes a picturesque sight with its old fortress. Ocean liners and freighters travel from Funchal to several European ports. The town is the main seaport and capital of the island group.

Bernard Regent, Hutchison Library

History. The Romans called the Madeiras the *Purpuriarae,* or "Purple" islands. The Portuguese first sailed to the island of Madeira in 1419. They gave the island that name—which means *wood*—because it was heavily forested. The Portuguese cleared some of the land by burning trees, the ashes from which gave the soil increased fertility. Funchal was founded in 1421. Porto Santo also was settled about that time. The Spaniards seized and held the islands from 1580 to 1640. The British occupied the Madeira Islands twice during the early 1800's. Douglas L. Wheeler

Madeira River, *muh DEER uh,* is a large branch of the Amazon River and an important trade waterway of South America. *Madeira* in Portuguese means *wood* or *timber.* The river was named for the great amount of driftwood that floats on its waters.

The Madeira begins where several large streams meet on the Brazil-Bolivia boundary. It flows northeast for about 2,000 miles (3,200 kilometers) before emptying into the Amazon River about 100 miles (160 kilometers) east of Manaus (see **Brazil** [terrain map]).

The mouth of the Madeira River is nearly 2 miles (3 kilometers) wide. Ships can sail upstream about 700 miles (1,100 kilometers) until they reach a series of rapids. Twenty of these rapids extend for 230 miles (370 kilometers), with a drop of 475 feet (145 meters). The area near the northern part of the river has rich gold deposits. One branch of the Madeira is the Rio Teodoro, once called Rio Duvida. This stream is 1,000 miles (1,600 kilometers) long. Theodore Roosevelt explored the Rio Teodoro in 1914. Gregory Knapp

Madero, *mah THAY roh,* **Francisco Indalecio,** *frahn SEES koh een dah LEH syoh* (1873-1913), led the Mexican Revolution of 1910 and was president of Mexico from 1911 to 1913. He is called the "Apostle of Mexican Democracy."

Madero was born in October 1873 into a wealthy family in the state of Coahuila. He opposed the Mexican dictator Porfirio Díaz and believed that democracy would solve the country's economic problems. In 1910, Madero ran against Díaz in a presidential election. When Madero gained popular support, Díaz imprisoned him in San Luis Potosí. Madero fled to the United States upon his release.

From San Antonio, Madero issued the Plan of San Luis Potosí, a call for armed struggle against Díaz's government. In February 1911, Madero returned to Mexico. The revolutionaries soon forced Díaz to resign. In October of that year, Madero was elected president.

As president, Madero struggled to meet conflicting demands. Some people wanted social and economic reforms, but others wanted no change. In February 1913, Madero was forced to resign. Opponents of the revolution assassinated him on Feb. 22, 1913. Ward S. Albro

Madison, Wisconsin (pop. 208,054; met. area pop. 426,526), is the capital and second largest city of the state. Only Milwaukee has more people. Madison is the home of the largest campus of the University of Wisconsin System. It also is a center of medicine, dairy-based agribusiness, and recreation. Madison is the trade center of a rich agricultural region. It lies in south-central Wisconsin. For location, see **Wisconsin** (political map).

Downtown Madison lies between Lakes Mendota and Monona, and Lake Wingra is in the western part of the city. These lakes help make Madison one of the nation's most beautiful state capitals.

Two land investors, James D. Doty and Stevens T. Mason, founded Madison in 1836. They named it for James Madison, the fourth president of the United States. Doty and Mason chose the site for the beauty of its lakes.

Description. Madison covers about 69 square miles (179 square kilometers), including about 21 square miles (54 square kilometers) of inland water. It is the county seat of Dane County. Madison's metropolitan area includes the county—1,233 square miles (3,193 square kilometers). The dome of the white granite State Capitol towers 286 feet (87 meters) above the heart of downtown Madison (see **Wisconsin** [picture: The State Capitol]). Federal, state, and municipal government buildings stand nearby. The University of Wisconsin campus lies about 1 mile (1.6 kilometers) west of the Capitol on the south shore of Lake Mendota. The campus and Capitol are connected by State Street, a pedestrian mall with many shops and restaurants.

©Kenn JeSchonek, PhotoGraphic Creations

Madison is the capital of Wisconsin and the home of the largest campus of the University of Wisconsin. The State Capitol rises in the heart of the downtown area, near the university campus.

The University of Wisconsin-Madison is one of the nation's largest universities. Madison is also the home of Edgewood College and the Madison Area Technical College. The city serves as a medical center, with the University Medical School, three hospitals, and a number of clinics.

Madison's cultural attractions include the State Historical Society of Wisconsin, Elvehjem Museum of Art, the Monona Terrace Community and Convention Center, and the Madison Civic Center. The Civic Center includes two theaters and the Madison Art Center, an art gallery. The University of Wisconsin operates the 1,200-acre (486-hectare) Arboretum in Madison. A zoo is located in Henry Vilas Park. Lakes in and near Madison provide boating, fishing, swimming, and water-skiing.

Economy of Madison depends heavily on government operations and on trade. Federal, state, and local government agencies and the University of Wisconsin employ about a third of Dane County's workers. Another third hold jobs in retail and wholesale trade and in such services as finance, insurance, and research. The city has over 100 research and testing laboratories.

About a tenth of the county's workers are employed in the area's more than 400 manufacturing plants. Farming and cattle raising in the area have helped make food processing the city's largest industry. The Oscar Mayer Division of Kraft Foods Incorporated is the city's largest private employer. American Family Mutual Insurance Group is the second largest employer. Madison's other major industries include the production of batteries, dairy equipment, and hospital supplies.

Railroad freight lines and bus and trucking companies serve Madison. Airlines use Dane County Regional Airport on Madison's east side.

Government and history. Madison has a mayor-council form of government. Voters elect the mayor to a four-year term and the 20-member Common Council to two-year terms.

Winnebago Indians lived in what is now the Madison area before white settlers came. In 1835, the site was bought by James D. Doty, a federal judge who later became governor of the Wisconsin Territory, and Stevens T. Mason, the governor of Michigan Territory. In 1836, the first Wisconsin Territory legislature made Madison the capital, even though the community did not yet exist. Its first white settlers, Eben and Rosaline Peck, arrived from nearby Blue Mounds in 1837. They erected a hotel for the workers who built the first Capitol.

Madison began functioning as the capital in 1838 and remained the capital when Wisconsin gained statehood in 1848. Madison was incorporated as a village in 1846 and became a city in 1856.

The Oscar Mayer company opened its meat-packing plant in the city in 1919 and helped make Madison a major food-processing center. During the 1920's, the city became the headquarters of the Progressive Party, led by the La Follette family of Madison. This party pioneered in social reform legislation.

During the 1960's, a rapid increase in employment by the federal, state, and municipal governments in Madison created a population boom. Since the early 1970's, many buildings in downtown Madison have been rehabilitated. One major rehabilitation project was the creation of the Civic Center, a performing arts complex completed in 1980. The Monona Terrace Community and Convention Center, completed in 1997, was built according to plans by the famous American architect Frank Lloyd Wright.

In 2001, Madison's city council approved plans for the construction of a downtown arts district. The plans included the expansion and renovation of the Civic Center and the Madison Art Center. Completion was scheduled for 2005. Doug Moe

Madison, Dolley Payne (1768-1849), a famous Washington hostess, was the wife of United States President James Madison. She is best known for her pleasant, open direction of White House social life. She relaxed the formal etiquette that had been practiced before her.

She and Madison married in 1794, when he was a congressman. While Madison served as secretary of state under President Thomas Jefferson, a widower, Mrs. Madison often helped Jefferson entertain guests. She also entertained frequently on her own. Mrs. Madison was noted for her charm and tact. At her home, people of strongly differing views could meet at ease.

Mrs. Madison was born in Guilford County, North Carolina, the third child of Quaker parents. She spent her childhood in Scotchtown, Virginia. In 1783, the family moved to Philadelphia. Dolley and John Todd, Jr., a lawyer and a Quaker, were married in 1790. They had two sons. Todd and one of the sons died in 1793. When she married Madison in 1794, she was expelled from the Society of Friends because of her marriage to a non-Quaker. The couple had no children. After Madison's two terms as president, the couple retired to Montpelier, his Virginia plantation. In 1837, after his death, she returned to Washington to live. There she resumed her social leadership, opening her home to large public receptions on New Year's Day and Independence Day.

Detail of an oil painting on wood (about 1810) by Gilbert Stuart; National Gallery of Art, Washington, D.C., Ailsa Mellon Bruce Fund.

Madison, James (1751-1836), the fourth President of the United States, is often called the Father of the Constitution. He played a leading role in the Constitutional Convention of 1787, where he helped design the checks and balances that operate among Congress, the President, and the Supreme Court. He also helped create the U.S. federal system, which divides power between the central government and the states.

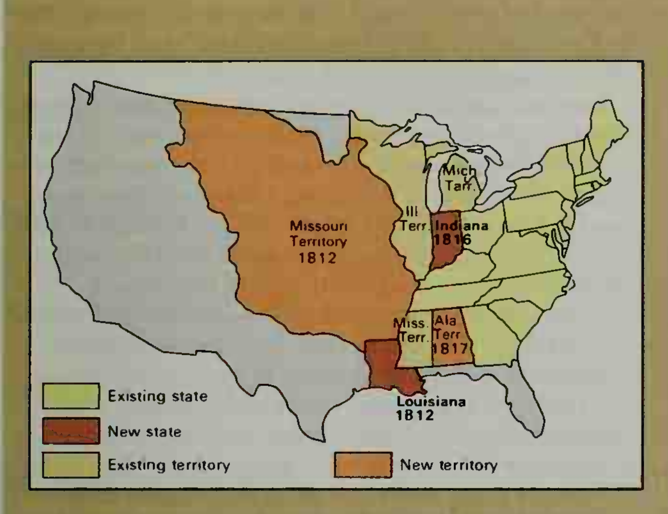
Madison served his home state—Virginia—and the United States in many roles over his 40 years in public life. Before he became President, Madison had served as secretary of state under President Thomas Jefferson. Both as secretary of state and as President, Madison tried to keep the United States from being drawn into conflicts between European countries. In 1812, however, President Madison led the United States into a war against Great Britain after Britain had interfered with U.S. shipping. During the war, British troops captured Washington, D.C., where they burned the Capitol, the White House, and other government buildings. As President, Madison followed policies that generally resulted in U.S. economic growth and westward expansion.

Madison was a close friend of Thomas Jefferson, who also was a Virginian. The two men formed an important political partnership. During the Revolutionary War in America, they worked together for American independence.

After the United States won independence, Madison favored the formation of a strong federal government. In the 1790's, however, he and Jefferson resisted the efforts of Alexander Hamilton to establish a national bank and so make the central government even stronger. Hamilton was President George Washington's treasury secretary.

Madison and Jefferson also opposed Hamilton's attempts to promote the growth of manufacturing in the United States. They wanted the country to remain a farming republic. They organized people who opposed Hamilton's policies into the Democratic-Republican Party, the forerunner of today's Democratic Party.

Early life



James Madison was born in the home of his mother's parents on March 16, 1751 (March 5 by the calendar then in use). They lived at Port Conway, Va., about 12 miles (19 kilometers) from Fredericksburg. James was the eldest of 12 children. The families of his father, James Madison, and his mother, Nelly Conway Madison, had settled in Virginia during the 1600's. Many slaves worked on the Madison plantation, Montpelier, near what is now Orange, Va.

James was a frail and sickly child. He studied with private tutors and attended the Donald Robertson School in King and Queen County. At the age of 18, he entered the College of New Jersey (now Princeton University). He took an active interest in politics and was an early member of the American Whig Society. Madison studied very hard and completed the regular course at the college in two years. He graduated in 1771.

Madison spent the next six months studying Hebrew, philosophy, and other subjects that showed his deep interest in religious questions. A weak speaking voice prevented him from taking up a career as a minister. He soon turned his attention to politics.

Political and public career

Entry into politics. Madison entered politics in 1774, when he was elected to the Committee of Safety in Or-

Two new states—Louisiana in 1812 and Indiana in 1816—joined the United States during Madison's presidency, making a total of 19 states in the Union. Congress established the Missouri Territory in 1812 and the Alabama Territory in 1817.

The world of President Madison

Construction of the National Road began in 1811. The road stretched from Maryland to Illinois and provided a major route to the West.
The steam-powered printing press, invented by the German printer Friedrich Koenig in 1811, enabled newspapers to print large numbers of copies cheaply.
The War of 1812 was fought by the United States and Great Britain from 1812 to 1815. British troops captured Washington, D.C., and burned the Capitol and other buildings. However, the war ended without a victory for either side.
Jane Austen's novels established her as one of the great writers in English literature. Her works included *Pride and Prejudice* (1813), *Mansfield Park* (1814), and *Emma* (1816).
"The Star-Spangled Banner," which became the national anthem of the United States, was written by Francis Scott Key in 1814. Key, an American lawyer, wrote the song after watching a British attack on Baltimore during the War of 1812.
The Hartford Convention, a meeting of New England leaders, took place in Hartford, Conn., in 1814 and 1815. The participants met to discuss their opposition to the War of 1812.
The Battle of Waterloo in 1815 brought defeat to the French Emperor Napoleon I and ended his plans to rule Europe.
The stethoscope, used to listen to the heart and other organs, was invented by French doctor René Laënnec in 1816.
The first savings banks in the United States were founded in Philadelphia and Boston in 1816. Such banks, which are nonprofit organizations created to promote saving, became the most common type of thrift institution in the Northeast.

WORLD BOOK map

ange County, Virginia. Committees of this kind provided local government in the days when the British colonial government was crumbling. In 1776, Madison helped draft a new Virginia constitution and the Virginia Declaration of Rights. Other colonies later drew upon these documents in writing their own constitutions.

Madison served in Virginia's revolutionary assembly in 1776, when he met Thomas Jefferson. The two men soon began a lifetime friendship.

Madison was defeated for reelection in 1777. But in 1778, the Virginia Assembly elected Madison to the Governor's Council, an advisory group. He held this post until December 1779, when he was elected to the Continental Congress.

Madison took his seat in Congress in March 1780. In those days, Congress had no power to raise taxes and found it difficult to pay national debts. Madison strongly favored increasing the powers of Congress in financial matters. He also advocated many other measures to stabilize and dignify the government.

Virginia assemblyman. Madison returned to Virginia in 1783. By that time, Americans generally recognized him as the ablest member of Congress. He planned to study law, history, and the sciences. Madison's studies were partially interrupted when the people of Orange County elected him to the state assembly for three successive one-year terms.

In the assembly, Madison continued the struggle Jefferson had begun for separation of church and state in Virginia. Madison's chief opponent was Patrick Henry, who favored state support for teachers of the Christian religion. In 1786, the assembly passed Virginia's Statute of Religious Freedom. Madison wrote to Jefferson that thus in Virginia "was extinguished forever the ambitious hope of making laws for the human mind."

Constitutional Convention. Madison represented Virginia at the Constitutional Convention of 1787. Although only 36 years old, he took a leading part. Madison fought for a stronger central government and drafted the Virginia Plan for the union. This plan, also called the Randolph Plan, foreshadowed the constitution that the convention finally adopted (see **Constitution of the United States** [The compromises]).

Madison proved valuable to the convention in many ways. He had read deeply in political history and knew firsthand the weaknesses of the Articles of Confederation, the basic law that the Constitution later replaced. Madison also kept a more complete record of the debates that took place at the convention than did anyone else who attended them.

Madison next served as a member of the convention that was called in Virginia to consider whether the state should ratify the new Constitution. He also joined Alexander Hamilton and John Jay of New York in writing *The Federalist,* a series of proratification letters to newspapers. Scholars still consider these letters the most autho-

Important dates in Madison's life

1751 (March 16) Born at Port Conway, Va.
1779 Elected to the Continental Congress.
1787 Served at the Constitutional Convention.
1789 Elected to the U.S. House of Representatives.
1794 (Sept. 15) Married Dolley Payne Todd.
1801 Appointed secretary of state.
1808 Elected President of the United States.
1812 Recommended war with Britain. Reelected President.
1829 Served at the Virginia Constitutional Convention.
1836 (June 28) Died at Montpelier, his family estate.

ritative explanation of the American constitutional system. See **Federalist, The.**

Congressman. Madison's efforts on behalf of the Constitution cost him the support of Virginians who opposed a stronger union. They united in the Virginia legislature to defeat him in 1788 for a seat in the first United States Senate. Early the next year, Madison defeated James Monroe in an election for the U.S. House of Representatives.

Madison, one of the ablest members of the House, proposed resolutions for organizing the Departments of State, Treasury, and War. He also drafted much of the first tariff act. Most important, he was largely responsible for drafting the first 10 amendments to the Constitution, the Bill of Rights (see **Bill of rights**).

At first, Madison supported many policies of President George Washington's first Administration. But he gradually came to oppose the financial plans of Washington's treasury secretary, Alexander Hamilton. Madison believed that Hamilton's plans favored wealthy Easterners at the expense of ordinary citizens, particularly small farmers in what were then the Southern and Western United States. As a result, Madison turned against the Washington Administration and Hamilton's Federalist Party. In 1791 and 1792, Madison and Jefferson formed the Democratic-Republican Party to oppose the Federalists.

In Philadelphia in 1794, Madison met and married Dolley Payne Todd, a young widow. By 1797, he had become weary of politics and retired to his estate. In 1798, Congress passed the Alien and Sedition Acts (see **Alien and Sedition Acts**). Madison was outraged. He drafted the Virginia Resolutions of 1798, proposing joint action by the states in declaring these laws unconstitutional. He was elected to the Virginia legislature in 1799 and 1800 and led the fight against what he considered Federalist efforts to undermine basic human rights.

Oil portrait on canvas (1817) by Bass Otis; New-York Historical Society, New York City

Dolley Madison, the President's wife, was famous for her hospitality. She served as White House hostess during the Administrations of both Madison and Thomas Jefferson, a widower.

Secretary of state. Thomas Jefferson became President in 1801 and appointed Madison secretary of state. The purchase of Louisiana was the most important success in foreign relations during Jefferson's presidency (see **Louisiana Purchase**). War with the Barbary pirates between 1801 and 1805 caused excitement throughout the country. The peace treaty signed with Tripoli brought only brief satisfaction. The pirates soon began preying on U.S. shipping again (see **Barbary States**).

Madison and Jefferson failed to force Great Britain and France to respect the rights of Americans on the high seas. The British and French were fighting each other in the Napoleonic wars, and each had blockaded the other's coast. American ships that tried to trade with either country were stopped by warships of the other. Many American seamen were seized and forced to serve on British or French warships. The Embargo Act of 1807 attempted to protect American ships by prohibiting them from sailing into foreign ports. It also barred exports from the United States. But the loss of trade brought widespread economic distress to the United States, and many Northern merchants evaded the embargo. In the end, the embargo hurt Americans more than it did the British or French.

The Embargo Act was repealed in 1809. In its place, Congress passed the Non-Intercourse Act, which opened trade with all countries except Great Britain and France. Congress hoped this law would force the British and French to recognize American commercial rights.

Jefferson favored Madison to succeed him as President. Madison received 122 electoral votes to 47 for the Federalist candidate, former minister to France C. C. Pinckney. For votes by states, see **Electoral College** (table). Madison's running mate was George Clinton of New York.

Madison's first Administration (1809-1813)

Events leading to war. Trade with Britain and France was still the government's greatest problem when Madison became President. In spite of the Non-Intercourse Act, American merchants continued to trade with those two countries, and British and French warships continued to interfere with American shipping. In 1810, Congress passed a bill that reopened trade with Britain and France. This act stated that if either Britain or France ended its attacks on American ships, the United States would stop trading with the other country. But the plan backfired. The French Emperor Napoleon I announced that he would revoke the French blockade against neutral trade with Great Britain. But at the same time, he issued secret orders that maintained the French blockade against American shipping. Madison halted all trade with Great Britain, but the French continued to stop American ships.

Americans were angered by France. Reports that the British were stirring up Indians in the West also aroused feelings against the British. These reports seemed to be confirmed when Tecumseh, chief of the Shawnee tribe, tried to organize an Indian alliance to fight the Ameri-

cans. The alliance dissolved after Governor William Henry Harrison of the Indiana Territory defeated the Indian forces in the Battle of Tippecanoe on Nov. 7, 1811 (see **Harrison, William Henry** [Entry into politics]). But people throughout the West believed the British as well as the Indians were their enemy.

Adding to the war feeling was a strongly nationalistic generation that had arisen in politics. It included many people who felt a war would result in the annexation of Canada and Spanish Florida. Henry Clay of Kentucky, Felix Grundy of Tennessee, and John Calhoun of South Carolina acted as its spokesmen in the House.

"Mr. Madison's War." Madison knew the United States was unprepared for war, and that New England merchants feared war would destroy trade. But he also knew people outside New England wanted it, and that the nation could tolerate no more insults from Britain. He finally recommended war, and Congress approved it on June 18, 1812. The Federalists opposed the conflict and called it "Mr. Madison's War." A few months later, Madison was reelected President by 128 electoral votes to 89 for Mayor DeWitt Clinton of New York City (see **Electoral College** [table]). Madison's running mate was Governor Elbridge Gerry of Massachusetts.

Madison's second Administration (1813-1817)

Progress of the war. At the start of the war, the British Navy clamped on a blockade that the pitifully small U.S. Navy could not break. American land forces attacked Canada in 1812 but were defeated. The fight for Canada continued for two years, with no decisive victories on either side. In 1814, Napoleon was defeated in Europe. Britain then sent experienced troops to Canada, ending American hopes for conquest.

In the summer of 1814, General Winfield Scott fought the British to a standstill at Chippewa and Lundy's Lane in southern Ontario. British troops invaded Maryland and, on August 24, burned the Capitol and other public buildings in Washington. Only heroic resistance at Fort McHenry kept the British from capturing Baltimore.

In September 1814, American forces stopped an invasion of British troops that were moving south down the western shore of Lake Champlain. Early in 1815, Andrew Jackson won a stunning victory at New Orleans. The war ended with the Treaty of Ghent, which went into effect in February 1815. It settled none of the problems that had caused the war. But it did preserve American territorial integrity (see **Ghent, Treaty of; War of 1812**).

In 1814 and early 1815, before the end of the war, New England Federalists had held a closed meeting known as the Hartford Convention. The convention passed resolutions against the war and proposed making New England more independent of the federal government. Many people believed that the convention was planning secession of the New England states. As a re-

sult, the Federalist Party was branded as unpatriotic, and it fell apart as a national organization shortly after James Monroe was elected president in 1816. See **Hartford Convention.**

The growth of nationalism. Albert Gallatin, Madison's first secretary of the treasury, believed that the War of 1812 had "renewed and reinstated the national feeling of character which the Revolution had given and which was daily lessening. The people ... are more American; they feel and act more as a nation." The end of the war ushered in "the era of good feeling." With the end of the Federalist Party, political conflicts were submerged within the Democratic-Republican Party.

During the two years after the war, trade expanded, and the country experienced great economic growth. In 1816, Madison signed a bill that created the country's second national bank. The first such bank had operated from 1791 to 1811. Changes in federal policy also made it easier for settlers to buy frontier land, and the rate of westward migration increased. In addition, Madison approved the tariff of 1816, which introduced the principle of protecting American industries.

Life in the White House. Mrs. Madison began an extravagant round of parties as soon as her husband took office. She served elaborate dinners and delighted in surprising her guests with delicacies.

The British invasion of the capital and the burning of the White House ended social gaiety. The Madisons fled Washington. When they returned, they established a new residence in the Octagon House, a private home just west of the White House. In 1815, they moved to a house on the corner of Pennsylvania Avenue and 19th Street. Dolley Madison resumed her busy social life but longed to reoccupy the White House. However, reconstruction work proceeded slowly, and the Executive Mansion was not ready for occupancy until nine months after Madison left office in 1817.

Later years

In retirement at Montpelier, Madison busied himself with the affairs of his estate. After Jefferson's death in 1826, he became *rector* (president) of the University of Virginia. Madison died at Montpelier on June 28, 1836. His widow returned to Washington, where she lived until her death in 1849. The Madisons are buried in a family plot near Montpelier. They had no children, but they reared the son of Mrs. Madison by her first husband.

Questions

Why is Madison called "the Father of the Constitution"?
What were some important principles that Madison supported in the Continental Congress?
What effect did Madison have on the relationship of church and state in Virginia?
How did Madison prove valuable in the first U.S. Congress?
How did the War of 1812 affect American nationalism?
Why did Madison draft the Virginia Resolutions of 1798?
What was Madison's relationship to *The Federalist?*
Why did Madison oppose the growth of manufacturing in the United States?
How did Dolley Madison shine as first lady?

Quotations from Madison

The following quotations come from some of James Madison's speeches and writings.

Those who hold and those who are without property have ever formed distinct interests in society.
The Federalist, Number 10, November 1787

If men were angels, no government would be necessary.
The Federalist, Number 47, January 1788

The accumulation of all powers, legislative, executive, and judiciary, in the same hands, whether of one, a few, or many, and whether hereditary, self-appointed, or elective, may justly be pronounced the very definition of tyranny.
The Federalist, Number 47, January 1788

I believe there are more instances of the abridgment of the freedom of the people by gradual and silent encroachments of those in power than by violent and sudden usurpations.
Speech at the Virginia Ratifying Convention, June 16, 1788

Peace, at all times a blessing, is peculiarly welcome ... at a period when the causes for the war have ceased to operate, when the government has demonstrated the efficiency of its powers of defense, and when the nation can review its conduct without regret and without reproach.
Message to Congress announcing the end of the War of 1812, Feb. 18,1815

The advice nearest to my heart and deepest in my convictions is that the Union of the states be cherished and perpetuated.
"Advice to my Country," 1834

Madonna (1958-), an American singer, dancer, and actress, is one of the world's best-known rock music performers. She also writes many of her own songs and has helped produce her own records and music videos.

Madonna was born in Bay City, Michigan. Her full name is Madonna Louise Veronica Ciccone. She studied dance at the University of Michigan but left school in 1978 to pursue a dancing career in New York City. She soon switched to singing and songwriting. Her album *Like a Virgin* (1984), which included the hit single "Material Girl," became the first album by a woman artist to sell more than 7 million copies.

Madonna's bold lyrics and flashy costumes gave her a sexy, independent, often shocking image. Some of her songs, including "Like a Virgin" from her 1984 album and "Like a Prayer" (1989), became controversial for mixing sexual and religious references. The sexual content of her 1992 album *Erotica* and a book of photographs of her called *Sex* (1992) stirred additional controversy.

Madonna acted in David Mamet's play *Speed-the-Plow* (1988) in New York City. She appeared in several motion pictures, including *Desperately Seeking Susan* (1985) and *A League of Their Own* (1992). In 1996, she starred as Eva Perón, Argentina's first lady, in the film version of Andrew Lloyd-Webber's *Evita.* Don McLeese

Madonna and Child are the Virgin Mary and the infant Jesus in works of art. The Madonna and Child rank among the most important art subjects that the Christian religion has inspired.

Madonna means *my lady* in Italian. But the term has come to mean *the Virgin Mary.* Painters and sculptors produced some of their greatest works on the Madonna during the Renaissance (see **Renaissance**). Michelangelo's *Medici Madonna* is one of the finest sculptures of the Madonna. Terra-cotta figures of the Madonna by the sculptor Luca della Robbia are well known (see **Della Robbia, Luca** [picture: Luca della Robbia created *Madonna and Child Jesus*]). For other pictures of sculptures of the Madonna, see **Sculpture** (Medieval sculpture; picture); **Stoss, Veit.**

Painters of the Madonna. Saint Luke painted the first Madonna picture, according to legend. But the Virgin Mary and Child became symbols of the accepted Christian faith only after the Council of Ephesus, in present-day Turkey, in A.D. 431. Then the number of Madonna pictures began to increase. The oldest Madonna pictures are those found in the catacombs of the early Christians.

The Alba Madonna, an oil painting on canvas; © Board of Trustees, National Gallery of Art, Washington, D.C.

The Madonna and Child were painted in a pastoral setting by the Italian Renaissance artist Raphael. The painting shows the Christ Child clutching a cross as the Virgin Mary and John the Baptist look on. Raphael completed the circular painting in about 1509.

Stiff images set against a gold background from the Byzantine period served as models for other artists until the 1200's. Then the painters of the early Renaissance introduced a style that featured more background scenery. Giovanni Cimabue, the first of these painters, tried to put natural life into his paintings instead of copying the Byzantine types of figures.

The Madonna and Child was one of the most popular subjects for painters in the later Renaissance period. Raphael produced some of the greatest paintings of the Madonna. His painting *Sistine Madonna,* completed in 1515, hangs in Dresden, Germany. It shows the Virgin Mary carrying the infant Jesus in her arms. On one side, Pope Sixtus II kneels in prayer. Saint Barbara kneels on the other side. Below, two cherubs lean forward. Raphael originally painted this work as an altarpiece for the Church of San Sisto in Piacenza.

Other great painters who portrayed the Madonna included Giovanni Bellini, Leonardo da Vinci, Giorgione, Fra Filippo Lippi, Andrea del Sarto, and Titian.

Types of Madonna paintings. Paintings of the Madonna are usually divided into five classes, according to the general styles of treatment:

(1) *Portrait of the Madonna.* In this class, the Madonna usually appears as a half-length figure against a background of solid gold leaf, or with cherubs. She wears a blue robe, starred or marked with gold, often draped over her head. The first paintings of the Madonna, in the Greek or Byzantine period, belong to this group. This type evolved into the *Madonna of Humility,* in which the Madonna sits humbly on the ground while holding the Child. Baldovinetti's *Madonna,* exhibited in the Louvre, Paris, is an example from the late Renaissance.

(2) *The Madonna enthroned.* The Madonna sits on a throne or platform in this largest class of paintings. The treatment varies widely. Examples include *Virgin and Child Enthroned with Angels and Saints* by an unknown Byzantine artist in the **Painting** article and *The Madonna Enthroned with Angels* by the Italian artist Cimabue in the **Renaissance** article. For another example, see **Lippi, Filippo** (picture: *Madonna and Child*).

(3) *The Madonna in glory.* The Madonna and her attendants hover in the sky in paintings of this group. Heaven is suggested by a *halo* (circle of light), clouds, or cherubs, or by posing the figures in air just above the earth. The halo originally surrounded the entire figure, instead of only the head. It was generally oval in shape. Examples of this type of painting include *The Sistine Madonna* by Raphael; and *Madonna of the Stars* by Fra Angelico, in the monastery of San Marco in Florence. El Greco's *The Virgin with Saint Inés and Saint Tecla* is another example of this type of painting.

(4) *The Madonna in pastoral scenes.* Paintings in this class have a landscape background. Two well-known examples are reproduced in the **Painting** article: *Madonna of the Goldfinch* by Raphael and *Madonna of the Rocks* by Leonardo da Vinci.

(5) *The Madonna in a home environment.* This type of composition shows the Madonna and Child receiving homage in a realistic setting. It was especially popular in northern European art. *Madonna* by Quentin Massys pictures a Flemish bedroom of the 1400's. In *The Madonna and Child with Chancellor Rolin,* Jan van Eyck pictured the Madonna in Flemish scenery of the 1430's (see **Renaissance** [picture: A northern Renaissance painting]). In the 1600's, Rembrandt followed this tradition by showing the Holy Family in Joseph's carpenter shop.

Madrid, *muh DRIHD* (pop. 2,909,792), is the capital and largest city of Spain. It stands on a plateau about 2,150 feet (655 meters) above sea level and is one of the highest capitals in Europe. Madrid became the capital largely because of its location near the exact geographic center of Spain. For the location of Madrid, see **Spain** (political map).

Spain had reached its height as a colonial power when King Philip II made Madrid the capital in 1561. The Spanish colonial empire began to decline during the 1600's, but Madrid remained an important center of government and culture. In the last half of the 1900's, Madrid also became one of Spain's leading industrial cities.

The city covers about 234 square miles (606 square kilometers). The northwest part of Madrid suffered severe damage during the Spanish Civil War (1936-1939), but the area and its buildings have since been reconstructed and restored.

A large, crescent-shaped plaza called the Puerta del Sol (Gate of the Sun) marks the center of downtown Madrid. One of the city's main streets, the Calle de Alcalá, extends northeastward from the Puerta del Sol. The old section of Madrid lies west of the Puerta del Sol. A number of the buildings that line the narrow, winding streets of this area were built during the 1500's and 1600's.

Madrid's modern business district stretches along the Calle de la Castellana. Banks, hotels, restaurants, stores, and theaters line the Gran Vía, the main street of the shopping and tourist section. The Salamanca district, a residential area built chiefly in the late 1800's and the 1900's, occupies the near northeast part of the city. A huge park called the Retiro covers more than 350 acres (142 hectares) just southeast of the center of Madrid.

Nearly all of Madrid's famous buildings, museums, and monuments are in or near the old section and the business district. The Royal Palace, built in the 1700's, stands at the western edge of the old section. The Spanish royal family lived in the palace until 1931, when King Alfonso XIII was forced to leave the country. Elaborate gardens border the palace, which is now a museum. In addition, Madrid has a number of lovely old churches and impressive public squares with fountains and statues.

Since 1950, rapid population growth has caused Madrid to expand in all directions. Today, residential areas and industrial suburbs surround the central city. Like other rapidly growing cities, Madrid has such problems as air pollution and crowded living conditions. Many of the city's trees have been cut down to widen streets and to provide parking space for the increasing number of automobiles.

The people of Madrid are called *Madrileños* (pronounced *MAH druh LAYN yohs).* They speak Castilian

James Davis Travel Photography

Madrid's Gran Vía is the main street of the city's shopping and tourist district. Banks, hotels, restaurants, stores, and theaters line both sides of this busy avenue.

Spanish, the official language of Spain. Most people live in apartments because there are few houses in the crowded city.

Most stores and offices in Madrid open at 9 a.m. and close at about 1:30 p.m., when Madrileños leave work to eat a leisurely lunch. The business places are open again from 5 p.m. to about 8 p.m. Like other Spaniards, most Madrileños have dinner between 9 p.m. and midnight. They like to dine at Madrid's many fine restaurants, which feature beef, lamb, and seafood dishes. Sidewalk cafes throughout the city are favorite meeting places, where Madrileños chat with friends.

Soccer ranks as Madrid's most popular sport. The Santiago Bernabéu stadium is the largest of three soccer stadiums in the city. It is home to Real Madrid, the city's premier soccer team. Large crowds also attend the bullfights held at the Plaza de Toros.

Education and cultural life. Madrid's educational institutions, museums, and libraries make the city the cultural center of Spain. The University of Madrid, the nation's largest university, occupies a section of Madrid called University City. The city also has a number of technical institutes.

Madrid is the home of one of the world's outstanding art museums, the Prado, which is also called the National Museum of Painting and Sculpture. The Prado houses a collection of more than 2,000 paintings by Spanish and foreign masters. The Prado's exhibits of Spanish paintings include more than 30 works by El Greco and more than 100 works by Francisco Goya. In addition, the museum displays 50 paintings by Diego Velázquez, including *Las Meninas,* which appears in the **Painting** article in *World Book.*

The Reina Sofia art museum houses Picasso's famous painting, *Guernica,* which appears in the **Picasso, Pablo** article in *World Book.* Other museums in Madrid feature exhibits on Spanish culture, natural history, and science. In addition, the city is the home of Spain's National Library and the National Historical Archives.

Climate. Madrid has a dry climate, with hot summers and cool winters. It receives an average of less than 17 inches (43 centimeters) of rain a year. Temperatures average about 40 °F (4 °C) in January and about 74 °F (23 °C) in July. During August, which is usually the hottest month in Madrid, Madrileños customarily leave Madrid for vacations at the beach or in the mountains.

Economy. From the mid-1500's to the mid-1900's, the economy of Madrid depended on the city's role as a government center. Most of the workers in Madrid had jobs related to politics or government administration. The city had almost no industry.

In the last half of the 1900's, the Spanish government encouraged large-scale industrial development in Madrid and its suburbs. Today, the city ranks second to Barcelona as a Spanish industrial center. Factories in the Madrid area manufacture automobiles, chemicals, clothing, electronics, trucks, and other products.

Highways and railroads link Madrid to other Spanish

Robert Frerck, Odyssey Productions

Apartment buildings overlook a park on Madrid's north side. Most of the city's people live in apartments.

cities. Barajas International Airport lies about 7 miles (11 kilometers) northeast of downtown Madrid.

History. In the A.D. 900's, the Moors, a Muslim people, built a fortress called Magerit on the site of what is now Madrid (see **Moors**). Spanish Christians, under King Alfonso VI of León and Castile, gained control of the area in 1083.

Madrid remained a small, unimportant town until 1561, when Philip II made it the capital of Spain. Philip, who ruled a huge colonial empire, chose Madrid primarily because of its central location. During the late 1500's and early 1600's, Madrid grew rapidly and became one of the great cities of western Europe. Wealthy aristocrats and royal officials built homes there. But the rapid population growth created problems. Most Madrileños were poor and lived in shabby, crowded neighborhoods. Epidemics and a high crime rate made the city unsafe. During the 1700's, the government took steps that made Madrid a cleaner and safer city.

French forces under Napoleon I occupied Madrid from 1808 to 1813. On May 2, 1808, a group of Madrileños staged an unsuccessful revolt against the French. This uprising started a Spanish resistance movement that in time helped drive the French out of Spain.

Madrid, unlike many cities in a number of countries, failed to develop large industries during the 1800's. As a result, it did not attract large numbers of workers, and its rate of population growth dropped.

Madrid attracted worldwide attention during the Spanish Civil War, which began in 1936. The city was the scene of fierce fighting between the Loyalists, who supported the government, and the rebel forces of General Francisco Franco. The Loyalists moved the capital to Valencia in 1936 and to Barcelona in 1937. After the defeat of the Loyalists in 1939, Franco reestablished Madrid as the capital.

In the last half of the 1900's, Madrid again experienced rapid population growth. Government programs to develop industry and to build modern housing and office buildings in the city helped contribute to Madrid's growth. Jesus Cruz

Madrid Hurtado, Miguel de la. See De la Madrid Hurtado, Miguel.

Madrigal, *MAD ruh guhl,* is a type of music in which two or more voices sing separate melodies to a literary text. Madrigals generally are sung with one voice per part and without instrumental accompaniment.

The term *madrigal* is applied to two types of Italian songs. The first developed in the early 1300's. Most of the songs had *pastoral* (rural) love texts, with melodies for two or three voices. This type died out by the middle 1400's. In the early 1500's, a new musical and poetic form developed. The texts to these madrigals were refined, serious poems. By the mid-1500's, madrigals had become more complex. They were characterized by as many as six different musical lines sung simultaneously, often in imitation of each other. A close connection existed between the music and the emotional content of the words.

By the early 1600's, the madrigal had become almost obsolete in continental Europe. However, the form became popular in England following the publication of a collection of Italian madrigals with English words called *Musica Transalpina* (1588). English madrigals took on their own characteristics, including frivolous lyrics and refrains of nonsense syllables. Katherine K. Preston

Madroña, *muh DROHN yuh,* also called *madrone,* is a small tree with white, urn-shaped flowers and leathery evergreen leaves. The rough, berrylike fruit has mealy flesh and hard seeds. It grows along the Pacific coast of North America, from southern California to British Columbia. James L. Luteyn

Scientific classification. Madroña belongs to the heath family, Ericaceae. It is *Arbutus menziesii.*

See also **Heath.**

Maelstrom, *MAYL struhm,* is a swift and dangerous current in the Arctic Ocean. This current sweeps back and forth between two islands of the Lofoten group off the northwestern coast of Norway. It has been a menace to sailors for hundreds of years. The Maelstrom becomes more dangerous when the wind blows against it between high and low tide. The waters then form immense whirlpools that destroy small ships.

Writers, including the Norwegian poet Peter Dass and the American author Edgar Allan Poe, have greatly exaggerated the Maelstrom's power. As a result, the meaning of the word *maelstrom* has come to include any kind of whirlpool or any turmoil of widespread influence.

Maeterlinck, *MAY tuhr lihngk,* **Maurice,** *moh REES* (1862-1949), was a Belgian dramatist, poet, naturalist, and philosopher. He won the 1911 Nobel Prize for literature.

His literary works are symbolic and philosophical. Their stories suggest the soul's search for perfection and understanding. In his most famous play, the fairy talelike *The Blue Bird* (1908), a child searches the world for happiness, only to find it in his own home. The more realistic short plays *The Blind* and *The Intruder* (both 1891) are stories of unhappiness that also stress the need to find love and happiness in everyday life. *Pelléas and Mélisande* (1893) is a symbolic drama about ideal lovers destroyed by their search for perfection.

Maeterlinck also wrote two novels and four volumes of poetry. He turned from symbolic writing to direct expression of his philosophy in essays, such as the collection *The Treasure of the Humble* (1896). He often drew on his close study of nature in these essays. In *The Life of the Bees* (1901) and *Life and Flowers* (1907), he used his appreciation and understanding of nature as the basis for analysis of human behavior.

Maeterlinck was born in Ghent. He lived much of his life in France, and he wrote in French.

Maeve, Queen, was the legendary warrior queen of Connacht in Ireland. Her exploits are recorded in the tale of *The Cattle Raid of Cooley* in which the hero Cuchulainn defended Ulster from Maeve's attack. Maeve, also spelled *Mave,* is said to have lived in the first 100 years after Christ's birth and to have held her court at Cruachan, now Rathcroghan, in Roscommon. She was the daughter of the high king of Ireland, Eochaid Feidlech, and the wife of King Ailill. Maeve ruled Connacht for about 80 years. The legends of Mab, the fairy queen, were possibly based on stories told about her. See also **Cuchulainn; Mythology** (The Irish cycles).

Maffei galaxies, *mah FAY ee,* often called *Maffei 1* and *Maffei 2,* are two large star systems. They probably belong to the group of galaxies that includes the earth's galaxy, the Milky Way. The Maffei galaxies are less than 12 million light-years from the earth. A light-year is the distance that light travels in a year. It equals about 5.88 trillion miles (9.46 trillion kilometers).

Each of the Maffei galaxies measures from 50,000 to 100,000 light-years in diameter. Maffei 1, the brighter of the two systems, may consist of as many as 100 billion stars. Maffei 2 has only about 10 billion stars. Astronomers classify Maffei 1 as an *elliptical galaxy* because of its oval shape. Maffei 2, like the Milky Way, resembles a flattened coil and is therefore classified as a *spiral galaxy.*

The Maffei galaxies remained unknown until 1968 because they are hidden from the earth by dense clouds of cosmic dust and gas in the Milky Way. The galaxies were discovered that year by the Italian astronomer Paolo Maffei, for whom they were named. Maffei photographed the galaxies through a telescope by using film that was sensitive to *infrared rays,* the invisible heat rays given off by the galaxies. Infrared rays, unlike light rays, can penetrate dust clouds. In 1971, astronomers at several California observatories determined the approximate size and shape of the Maffei galaxies.

Mafia, *MAH fee ah,* is a secret criminal society in Sicily. Crime groups stemming from the original Sicilian Mafia operate in the United States and other countries. *Mafia* is also used as a general term for any underworld criminal organization.

The Mafia is made up of extended kinship groups called *mafiosi.* A Mafia member is called a *mafioso.* These groups originally maintained an ideal of manliness developed during the 1600's, when Sicily was ruled by Spain. The ideal called for refusal to cooperate with authorities and self-control in the face of hardships. In personal quarrels, a mafioso took the law into his own hands and gained respect by using violence. Any offense might trigger a campaign of vengeance called a *vendetta.* Mafiosi unofficially ruled part of western Sicily in the 1800's and early 1900's. Similar crime groups, such as the Camorra in Naples and the *Onorata Società* (Honored Society) in Calabria, developed in other parts of Italy.

In the late 1800's, southern Italians attempted to reproduce the Mafia in the United States. These groups did not have much power until Prohibition in the 1920's. Then, they greatly profited from *bootlegging*—the illegal making, selling, or transporting of alcoholic beverages. Also during this time, Italian dictator Benito Mussolini opposed mafiosi in western Sicily. Many fled to the United States and eventually became leaders of American organized crime.

After the end of Prohibition in 1933, these Italian-American groups, also called *crime families,* became active in other illegal practices. Their activities included gambling, *loan sharking* (lending money at unlawful rates of interest), and drug dealing. Authorities estimate that thousands of Mafia members and associates operate in the United States, particularly in New York City and Chicago.

Since the end of World War II (1939-1945), the Mafia in Italy has undergone major changes. Its rural base has moved into urban areas. It also has faced increased government opposition and feuds between Mafia groups.

Magarac, *MAG uh rak,* **Joe,** is a legendary hero of steelworkers. Folk tales about Magarac originated among Hungarian and other eastern European immigrants who settled in the steelmaking region of western Pennsylvania.

There has been a rich exchange of story elements between popular published versions of these legends and the oral traditions. Most of the legends about Magarac involve his great strength and physical endurance. Stories tell how he worked day and night at an open-hearth furnace. Magarac could squeeze hot steel through his fingers to make railroad rails and could forge horseshoes and cannonballs with his bare hands. According to one story, Magarac's life ended when he melted himself down to make the finest steel in the world. *Magarac* is a Slavic word that means *jackass,* but steelworkers used it as a term of admiration. Ellen J. Stekert

Magazines reach millions of people. Most readers buy them at newsstands or have them delivered at home. A large readership helps a magazine attract advertising, a major source of income.

Magazine is a collection of articles or stories—or both—published at regular intervals. Most magazines also include illustrations.

Magazines provide a wide variety of information, opinion, and entertainment. For example, they may cover current events and fashions, discuss foreign affairs, or describe how to repair appliances or prepare food. Subjects addressed in magazines include business, culture, hobbies, medicine, religion, science, and sports. Some magazines seek simply to entertain their readers with fiction, poetry, photography, cartoons, or articles about television shows or motion-picture stars. Thousands of magazines are published in the United States and Canada.

Magazines, like newspapers, represent the work of many writers. But magazines differ from newspapers in form and content. Magazines are designed to be kept much longer than newspapers. For this reason, most magazines have a smaller page size and are printed on better paper. Many have a binding of staples or stitching. In content, magazines often have less concern with daily, rapidly changing events than do newspapers. Most magazines have a cover featuring a photograph or a drawing rather than news stories like the first page of a newspaper.

Some periodicals that appear in newspaper form are really magazines. On the other hand, some weekly newspapers feature long, detailed articles like those found in many magazines.

Writing of different types—ranging from factual or practical reporting to a more personal or emotional style—regularly appears in magazines. Some of the best writers and thinkers in the nation write either occasionally or regularly for magazines. Many well-known authors published their early works in magazines.

Kinds of magazines

Magazines are usually divided into several large categories, including consumer magazines and specialized business magazines.

Consumer magazines appeal to the broad interests of the general public and are the ones usually seen on newsstands and in stores. Consumer magazines include children's magazines, hobby magazines, intellectual magazines, men's magazines, women's magazines, and news magazines. *Service magazines* include advice, how-to, medical, self-help, and religious publications. *Digests* reprint material, in a shorter form, that has appeared in other magazines or in books.

Specialized business magazines, also called *trade magazines,* appeal to the special interests of business, industrial, and professional groups. For example, *Aviation Week & Space Technology* focuses on the informational and product needs of people in the aerospace industry. Many highly specialized trade magazines control their circulation by mailing free copies to people whose jobs make them potential readers. By controlling their circulation, trade magazines limit their costs and attract particular advertisers. As a result, they can succeed with circulations that are much smaller than those of consumer magazines.

Other magazines include *association magazines,* which are published for the membership of organizations. They are often distributed free to dues-paying members. *Modern Maturity,* the magazine of the American Association of Retired Persons, has a circulation of

more than 20 million, higher than any magazine available on the newsstand. *Sponsored magazines* and *custom publications* are developed from the needs of one or more advertisers. These magazines publish stories to attract readers who are likely to be interested in a sponsor's products. Advertising is restricted primarily or entirely to those products.

Magazines may also be grouped by the *demographics* or *psychographics* of their readership. Demographics refers to such information as the age, race, sex, education, income, location, and hobbies of a group. For example, *Rolling Stone* appeals to an audience that is mainly male and white, has an average age in the mid-20's, and enjoys rock music. Psychographics refers to people's attitudes and personality traits. *Rolling Stone* attracts readers who identify with young people and who have liberal political or social views.

How magazines are produced

Magazines must meet regular publishing deadlines. A newspaper may have one or more deadlines a day, but a magazine's deadlines are days or weeks apart.

Planning a magazine. Every issue of a magazine must be planned thoroughly before publication. Most monthlies, for example, are planned several months in advance. The editors and staff members first decide what major articles, stories, and other items will appear in the issue. They plan the illustrations, if any, at the same time. Regular columns and editorials must also be planned.

Making assignments. The editors assign articles to staff members or free-lance writers. Each article has a deadline and a specified length. Photographs may be taken by staff or free-lance photographers or purchased from picture agencies. Special drawings may be used to illustrate certain kinds of articles. Magazines sometimes publish unassigned articles and photographs by free-lance journalists who offer material for sale.

Scheduling the advertising. Ads are planned for an issue of a magazine while the writers work on their assignments. The editors and staff artists create a *layout,* which shows how the advertising and editorial material will be arranged on each page.

Editing and assembling an issue. After the articles have been written, one or more editors go over them to check their accuracy and readability. At most magazines, all the written material, called *copy,* is stored on a computer. Magazines use special computer programs called *page layout programs* to arrange the electronic copy in columns and to create a final page design.

If a magazine has the necessary equipment, it can also convert illustrations into electronic form and insert them into the page layout program. If a magazine does not have such equipment, it sends the original illustrations to the printer. The printer then converts them and combines them with the electronic text.

Magazines use a laser printer or some other device to print copies of the pages created by the page layout program. Editors review these copies, called *proofs,* and check for errors. After the editors have made all necessary revisions, the final version of the pages is sent to the printer.

In most cases, the printer, or sometimes the magazine itself, uses the electronic files of copy and illustrations to create film negatives or positives. The printer then uses the film to make printing plates or cylinders. In some cases, the printer can produce the plates or cylinders directly from the electronic files.

The most common method of magazine printing is *offset lithography.* Some magazines with large circulations are printed by the *gravure* process. See **Printing.**

How magazines earn income

Most magazines receive income from two sources: (1) advertising and (2) sales of the publication by subscriptions or by newsstand purchases.

Advertising ranks as the most important source of income for many magazines. Advertisers put their messages in magazines because these publications are read by certain groups. For example, a photography magazine attracts camera fans who may find its ads helpful in choosing certain photographic equipment. Advertisers of such equipment can reach many potential customers by putting ads in such a magazine. Advertisers must spend many thousands of dollars for one page of advertising space in a magazine that has a large circulation.

Many publishers conduct surveys to find out what groups of people read their magazines. These surveys can identify reader groups by age, income, occupation, race, sex, and other characteristics. Advertisers study such surveys to decide which magazines are read by the people most likely to buy their products.

Sales. Readers get many consumer magazines by subscription through the mail. Readers also buy many magazines at newsstands. Magazines to be sold on newsstands are shipped by airplane, train, and truck to local communities. Distribution companies then deliver them to newsstands.

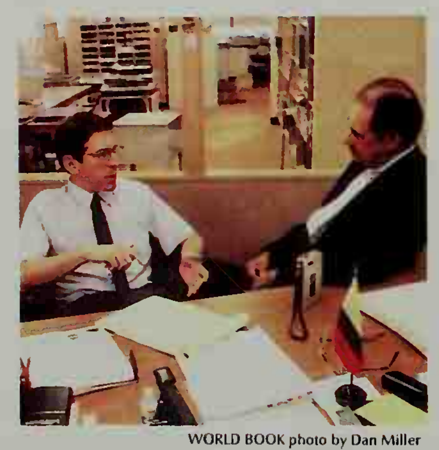
Subscription and newsstand sales cannot cover the production costs of most magazine publishers. The actual selling of a magazine is also expensive. Attracting subscribers, for example, may involve an expensive promotional campaign that attracts only a small number of new subscriptions. In newsstand sales, the publisher gets paid only for the magazines actually sold.

History

The earliest magazines probably developed from newspapers or from bookseller catalogs. Such catalogs, which reviewed books on sale, first appeared during the 1600's in France. Pamphlets published at regular intervals appeared in England and America in the 1700's, primarily as literary publications. They included *The Tatler* and *The Spectator,* both published in England.

One of the first English magazines, *The Gentleman's Magazine,* was published from 1731 to 1914. Edward Cave, an English printer, started it as a collection of articles from various books and pamphlets. Later, the magazine published original material. Samuel Johnson, a famous English writer and critic, contributed to it.

The first magazine published in America, the *American Magazine, or A Monthly View of the Political State of the British Colonies,* was published in 1741 in Philadelphia and lasted only three months. Mathew Carey, a Philadelphia printer and bookseller, started two early American magazines, *The Columbian* in 1786 and *The American Museum* in 1787.



In 1830, Louis A. Godey founded *Godey's Lady's Book,*

the first American magazine for women. Sarah Josepha Hale edited the magazine, which helped shape the tastes of thousands of women. Among the first influential intellectual magazines was *The Dial,* published in the early 1840's by New England transcendentalists and edited by Margaret Fuller (see **Transcendentalism**). In the mid-1800's, a number of important magazines were started. Frank Leslie began *Leslie's Weekly,* which was one of the first magazines to feature many illustrations. *The Atlantic Monthly,* launched in 1857, was first edited by the famous poet James Russell Lowell. During the American Civil War (1861-1865), many people read *Harper's Weekly* for its drawings of the battlefront.

In the late 1800's and early 1900's, reformers who exposed conditions in business, industry, and politics wrote for *Everybody's Magazine* and *McClure's Magazine.* These writers, called *muckrakers,* included Ray Stannard Baker, Lincoln Steffens, and Ida M. Tarbell. *McClure's Magazine,* founded by S. S. McClure, became one of the first successful inexpensive magazines. Before this time, magazines had been published mainly for wealthy people. *The Nation,* founded in 1865 as a liberal weekly newspaper, later became a magazine. The *Ladies' Home Journal,* founded in 1883, worked for social causes under editor Edward W. Bok after 1889. Important literary publications started in the early 1900's included *Vanity Fair* in 1914 and *The New Yorker* in 1925.

Trade magazines developed with and influenced the growth of American business. Important trade magazines founded since the 1800's include *The American Rail-Road Journal* in 1831, *Textile World* in 1868, *Motor Age* in 1899, *Advertising Age* in 1930, and *Computerworld* in 1967.

Henry R. Luce, who founded *Life, Time, Sports Illustrated,* and other magazines, was one of the leading magazine publishers of the 1900's. Another leading publisher, John H. Johnson, began publishing *Negro Digest* in 1942. Johnson later founded *Ebony* and other magazines written chiefly for African American readers.

Editors have also had major impact in shaping magazines. Clay Felker defined the modern city magazine with *New York.* Helen Gurley Brown with *Cosmopolitan* and Gloria Steinem with *Ms.* established new visions of women outside the home during the 1960's.

During the 1920's and 1930's, such general magazines as the *Saturday Evening Post* ranked as the major means of nationwide communication. These publications featured text and photographs on a wide range of subjects. But after the widespread growth of television in the 1950's, advertisers began to promote their products on TV rather than in general magazines. Television enabled the advertisers to reach larger audiences and to emphasize their message with motion. Since that time, the lack of advertising and an increase in overall costs have caused many general magazines to stop publishing or to publish less frequently.

As general magazines dwindled, specialized magazines called *niche publications* flourished. These targeted magazines, made possible by sophisticated market and circulation research, are designed to attract particular audiences and advertisers who want to reach them. Niche publications also cut postage and production costs by being better able to estimate sales. In the late 1980's, British-born editor Tina Brown reinvigorated the general magazine by reviving *Vanity Fair.* In 1992, she became editor in chief of *The New Yorker.*

A magazine publisher once needed relatively little money to launch a publication. For example, two prominent American magazines, *The New Yorker* and *Time,* were started in the 1920's with little funds. But today, high costs—particularly those involving production and mailing—can require a great deal of money to start and maintain a magazine. Hundreds of new and older magazines cease publication each year, but as many as 750 new magazines appear annually to meet the needs of groups of readers and advertisers. Abe Peck

Magazine is a military and naval term for a protected building or storage room for ammunition. The term comes from an Arabic word meaning *storehouse.* The ammunition supply chamber of a repeating rifle or machine gun is also called a magazine.

Shore magazines are usually concrete buildings shaped like beehives. They are half buried in the ground and are covered with earth. Some powder magazines are built in many compartments, each of which is covered with a light roof. If an explosion occurs, the damage will be confined to a small space and the force will move upward when the roof gives way.

On ships, magazines are placed as far as possible from the engines and firerooms and far below the water line. They are made up of many watertight rooms with steel walls. In the tropics, magazines are cooled by ventilators that pipe cool air from a refrigerator. Other pipes take away hot air. Ann Alexander Warren

Magdalene. See Mary Magdalene.

Magellan, *muh JEHL uhn,* **Ferdinand** (1480?-1521), was a Portuguese sea captain who commanded the first expedition that sailed around the world. His voyage provided the first positive proof that the earth is round. Magellan did not live to complete the voyage, but his imaginative planning and courageous leadership made the entire expedition possible. Many scholars consider it the greatest navigational feat in history.

Early life

Magellan was born about 1480 in northern Portugal. His name in Portuguese was Fernão de Magalhães. His parents, who were members of the nobility, died when he was about 10 years old. At the age of 12, Magellan became a page to Queen Leonor at the royal court. Such a position commonly served as a means of education for sons of the Portuguese nobility.

At the court, Magellan learned about the voyages of such explorers as Christopher Columbus of Italy and Vasco da Gama of Portugal. He also learned the fundamentals of navigation. In 1496, Magellan was promoted to the rank of squire and became a clerk in the marine department. There, he helped outfit ships for trade along the west coast of Africa.

Magellan first went to sea in 1505, when he sailed to India with the fleet of Francisco de Almeida, Portugal's first viceroy to that country. In 1506, Magellan went on an expedition sent by Almeida to the east coast of Africa to strengthen Portuguese bases there. The next year, he returned to India, where he participated in trade and in several naval battles against Turkish fleets.

In 1509, Magellan sailed with a Portuguese fleet to Melaka, a commercial center in what is now Malaysia. The Malays attacked the Portuguese who went ashore, and Magellan helped rescue his comrades. In 1511, he took part in an expedition that conquered Melaka. After this victory, a Portuguese fleet sailed farther east to the Spice Islands (also called the Molucca Islands). Portugal claimed the islands at this time. Magellan's close personal friend Francisco Serrão went along on the voyage to the Spice Islands and wrote to Magellan, describing the route and the island of Ternate. Serrão's letters helped establish in Magellan's mind the location of the Spice Islands, which later became the destination of his great voyage.

Magellan returned to Portugal in 1513. He then joined a military expedition to Morocco. On this expedition, Magellan suffered a wound that made him limp for the rest of his life.

Voyage around the world

Planning the expedition. After returning to Portugal from Morocco, Magellan sought the support of King Manuel I for a voyage to the Spice Islands. The best maps available had convinced Magellan that he could reach the Spice Islands by sailing south of South America. Magellan believed such a route would be shorter than the eastward voyage around the southern tip of Africa and across the Indian Ocean. However, Manuel disliked Magellan and refused to support the proposed voyage.

Magellan then studied astronomy and navigation for about two years in Porto in northern Portugal. In Porto, he met Ruy Faleiro, an astronomer and geographer who strongly influenced his ideas. Magellan and Faleiro concluded from their studies that the Spice Islands lay in territory that had been awarded to Spain in 1494 (see **Line of Demarcation**). Therefore, Magellan decided to seek support for his plans from the king of Spain.

In 1517, Magellan went to Spain. There, he presented his proposal for visiting the Spice Islands as part of a westward circumnavigation of the earth. The next year, Magellan convinced Charles I of Spain to support such a voyage. The king promised Magellan a fifth of the profits from the voyage to the Spice Islands, plus a salary.

Preparations for the expedition took more than a year. The Spaniards became suspicious of Magellan, partly because he recruited many Portuguese sailors. As a result, the king forced Magellan to replace most of the Portuguese with Spanish crewmen.

The voyage begins. On Sept. 20, 1519, Magellan set sail from Sanlúcar de Barrameda in southern Spain. Magellan commanded a total of 241 men and a fleet of five ships, the *Concepción, San Antonio, Santiago, Trinidad,* and *Victoria.* Dissatisfaction among the crewmen plagued the voyage from the beginning, and hostility among the Spaniards toward Magellan grew rapidly. About a month after the voyage began, the Spanish captain of the *San Antonio* challenged Magellan's authority, and Magellan had the captain arrested.

The fleet sailed across the Atlantic Ocean to the coast of Brazil. The ships then followed the South American coast to the bay where Rio de Janeiro now stands. They remained there for two weeks and then sailed south in search of a passage to the Pacific Ocean. However, the ships could not find a passage before the end of summer in the Southern Hemisphere. In late March 1520, Magellan's fleet anchored for the winter at Puerto San Julián in what is now southern Argentina.

Real Academia de Bellas Artes de San Fernando, Madrid, Spain
Ferdinand Magellan

During the winter, a storm destroyed the *Santiago.* In addition, a mutiny broke out shortly after the men set up their winter quarters. Magellan and loyal crew members put down the mutiny and executed the leader. They also marooned two other mutineers when the fleet sailed again.

Magellan and his crew resumed their voyage on Oct. 18, 1520. Three days later, they discovered the passage to the Pacific—a passage known ever since as the Strait of Magellan. As the fleet sailed through the strait, the crew of the *San Antonio* mutinied and returned to Spain. On November 28, the three remaining ships sailed out of the strait and into the ocean. Magellan named the ocean the Pacific, which means *peaceful,* because it appeared calm compared with the stormy Atlantic.

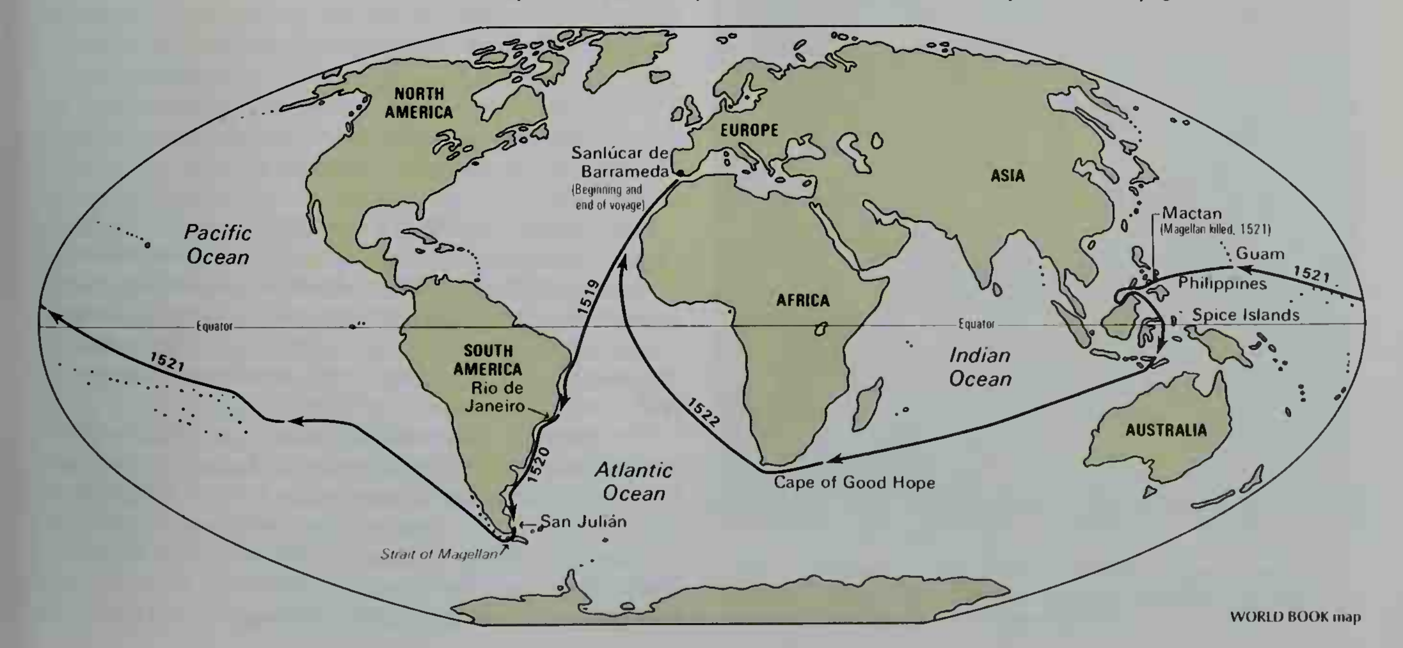
Sailing across the Pacific involved great hardship for Magellan and his crew. They were the first Europeans ever to sail across the Pacific, and it was far larger than anyone had imagined. They sailed for 98 days without seeing any land except two uninhabited islands. Their food gave out and their water supply became contaminated. They ate rats, ox hides, and sawdust to avoid starvation. Most of the crew suffered from scurvy, a disease caused by the lack of fresh fruits and vegetables. Nineteen men died before the fleet reached Guam on March 6, 1521.

Conflicts with the people of Guam and the nearby island of Rota prevented Magellan from fully resupplying his ships. But the crew seized enough food and water to continue on to the Philippines.

Magellan and his crew remained in the Philippines for several weeks, and close relations developed between them and the islanders. Magellan took special pride in converting many of the people to Christianity. Unfortunately, however, he involved himself in rivalries among the people. On April 27, 1521, Magellan was killed when he took part in a battle between rival Filipino groups on the island of Mactan.

The end of the voyage. After the battle on Mactan, only about 110 of the original crew members remained—too few to man three ships. Therefore, the men abandoned the *Concepción,* and the two remaining vessels sailed southward to the Spice Islands. There, the ships were loaded with spices. The leaders of the fleet then decided that the two ships should make separate return voyages.

The *Trinidad,* under the command of Gonzalo Gómez de Espinosa, tried to sail eastward across the Pacific to the Isthmus of Panama. Bad weather and disease disrupted the voyage, and more than half of the crew of the *Trinidad* died. The surviving members of the crew were forced to return to the Spice Islands, where the Portuguese imprisoned them.



The *Victoria,* commanded by Juan Sebastián del Cano, continued its westward voyage back to Spain. Like the *Trinidad,* the *Victoria* experienced great hardship, and many of the crew died of malnutrition and starvation. The *Victoria* finally reached Sanlúcar de Barrameda on Sept. 6, 1522, nearly three years after the voyage had begun. Only Del Cano and 17 other survivors returned with the ship.

Results of the voyage. One of the crew members who returned with Del Cano was an Italian named Antonio Pigafetta. He had faithfully written down the events of the voyage, and his journal is the chief source of information about the expedition. According to Pigafetta, the voyage covered 14,460 leagues (50,610 miles or 81,449 kilometers). Pigafetta praised Magellan for his courage and navigational skill. However, nearly everyone else at the time gave Del Cano the credit for the voyage. The Portuguese considered Magellan a traitor, and the Spanish condemned Magellan after they received reports of his harshness and of his errors in navigation.

Magellan failed to find a short route to the Spice Islands, but his voyage contributed greatly to knowledge about the earth. In addition, the discovery of the Strait

The voyage of Magellan 1519 to 1522

This map traces Magellan's search for a western passage to the Spice Islands. He became the first European to sail across the Pacific Ocean. Magellan was killed on the island of Mactan in 1521. One of his ships, commanded by Juan Sebastián del Cano, completed the voyage.

Detail of an engraving (1800's); Granger Collection

Magellan died in battle on the island of Mactan in the Philippines. Although he is remembered for leading the first naval expedition around the world, he did not complete the voyage.

of Magellan led to future European voyages to explore the vast Pacific. John Parker

Magellan, *muh JEHL uhn,* **Strait of,** is a narrow, rough waterway that separates the islands of Tierra del Fuego from the mainland of South America. The Strait of Magellan is almost at the southern end of the continent.

The Strait of Magellan is located at the southern tip of South America. The strait experiences high winds and heavy rains throughout the year.

WORLD BOOK maps

In 1520, Ferdinand Magellan, the Portuguese explorer, led the first European expedition through the strait during the first voyage around the world.

The Strait of Magellan is 350 miles (563 kilometers) long and varies from 2 to 20 miles (3 to 32 kilometers) in width. Before the Panama Canal opened, the strait and Cape Horn were the shortest water routes from the Atlantic Ocean to the Pacific Ocean. Jerry R. Williams

Magellanic Clouds, *MAJ uh LAN ihk,* are two galaxies visible in the Southern Hemisphere as small, hazy patches of light. They are the galaxies closest to the Milky Way, the galaxy that contains the sun, the earth, and the rest of our solar system. The Large Magellanic Cloud is about 160,000 light-years away from the earth, and the Small Magellanic Cloud is about 180,000 light-years away. A light-year is the distance that light travels in one year—about 5.88 trillion miles (9.46 trillion kilometers).

Astronomers classify the Magellanic Clouds as *irregular galaxies* because the distribution of the stars within them does not follow a particular pattern. The Magellanic Clouds contain billions of stars, but individual stars can be distinguished only with the most powerful telescopes. As a result of these stars' apparent closeness, the galaxies appear cloudy to the naked eye. The Magellanic Clouds also contain a huge quantity of gas. New stars are constantly forming from this gas, which is composed mainly of hydrogen. In addition, much of the light from the Magellanic Clouds comes from young, extremely luminous, hot blue stars that are surrounded by glowing clouds of this gas.

Because they are visible only in the Southern Hemisphere, the Magellanic Clouds were long unknown to astronomers in the Northern Hemisphere. They were first recorded in the early 1500's during the circumglobal voyage of the Portuguese explorer Ferdinand Magellan, after whom they were named. However, it was not until the early 1900's that the clouds were recognized as galaxies outside the Milky Way. Mark Morris

Maggiore, Lake. See **Lake Maggiore.**

Maggot, *MAG uht,* is the larva, or young, of many kinds of flies. The maggot has a soft body that usually tapers toward the front. It looks somewhat like a worm or caterpillar. It has no legs and no distinct head. Maggots move by wriggling or flipping their bodies. They are usually white but may be colored. Most maggots live buried in their food. Some are scavengers and live in dead or decaying matter. Others are parasites in animal and plant tissue. Still others prey on insects.

Magi, *MAY jy* or *MAJ eye,* were the hereditary members of a priestly class from Media, an ancient kingdom located in what is now northern Iran. A single member of the class was called *Magus.* The Magi were known for practicing magic, interpreting omens and dreams, and offering astrological sacrifices.

The Magi's vast knowledge of rituals gained them the reputation as the only true priests of Zoroastrianism, an ancient Persian religion founded by a prophet named Zoroaster. It is not known whether the Magi influenced Zoroaster, or if they became his followers. The Magi were said to keep watch upon a "Mount of the Lord" from generation to generation until a great star ap-

peared that would signal the coming of a savior.

The Bible describes how the Three Wise Men, or Magi, followed a star to Bethlehem and presented gifts of gold, frankincense, and myrrh to the baby Jesus (Matthew 2). Later tradition gave the three men the names of Melchior, Balthasar, and Gaspar. The Magi are frequently connected with Persian religious tales and are often shown in early Christian art wearing Persian clothes. Robert William Smith

See also **Epiphany**.

Magic is the supposed use of unnatural or superhuman power by a person to try to control human actions or natural events. Magic often seems to achieve results, but the results actually have other causes. For example, a person might cast a magic spell to make an enemy sick. The enemy may learn about the spell, become frightened, and actually feel ill.

People throughout the world have practiced magic from the dawn of history. But beginning in the 1600's, science has provided an increasingly greater understanding of the true causes of natural events. This increased scientific knowledge has reduced people's dependence on magic. But many people in nonindustrial societies still believe in magic. Even in industrial societies, many people still trust in such forms of magic as astrology and fortunetelling.

The word *magic* also refers to entertainment in which the performer does tricks of so-called magic. In such entertainment, neither the magician nor the audience believes that the performer has supernatural powers. For information on magical performances, see **Magician**.

Elements of magic

The practice of magic includes special words, actions, and objects. Most magic involves a person called a magician, who claims to have supernatural powers.

Magic words. To work most magic, the magician sings or speaks special words in a certain order. These words are called *incantations* or *spells.* Some spells form prayers to demons, spirits, or other supernatural forces. Many societies believe the magic will not work unless the magician recites the spells perfectly. Other magic words have no meaning, though they supposedly possess power when spoken by a magician.

Magic actions accompany the words spoken in performing much magic. Many of these movements act out the desired effect of the magic. For example, a magician trying to make rain fall may sprinkle water on the ground. The magician's combined words and actions form a ceremony called a *rite* or *ritual.*

Magic objects include certain plants, stones, and other things with supposed supernatural powers. Any such object may be called a *fetish* (see **Fetish**). But this term often refers to an object—for example, a carving or a dried snake—honored by a tribe for its magic powers. Many tribes believe fetishes have magic power because spirits live in these objects.

Many people carry magic objects called *amulets, charms,* or *talismans* to protect themselves from harm (see **Amulet**). Many amulets and talismans are stones or rings engraved with magic symbols.

The magician. In some societies, nearly everyone knows how to work some magic. In other societies, only experts practice magic. Magicians may be called *medicine men, medicine women, shamans, sorcerers,* or *witch doctors* (see **Shaman**). In many societies, magicians must inherit their powers. In others, any person may become a magician by studying the magical arts.

Many societies believe magicians must observe certain rules and *taboos* (forbidden actions) for their spells to work. For example, they may be required not to eat various foods or to avoid sexual activity for a certain period before the ceremony.

Kinds of magic

Many anthropologists classify magic as *homeopathic* or *contagious,* according to its basic principle. The Scottish anthropologist Sir James G. Frazer first described these types in his book *The Golden Bough* (1890).

Some people divide magic into *black magic* and *white magic.* Black magic harms people, but white magic helps them. Witches usually practice black magic. But a saint may cure a sick person using white magic.

Homeopathic magic is based on the belief that like produces like. In this type of magic, also called *imitative magic,* magicians act out or imitate what they want to happen. They often use a model or miniature of whatever they want to influence. For example, a fisherman may make a model of a fish and pretend he is netting it. He believes this ritual will assure him a good catch. In some European folk dances, the dancers leap high into the air to make their crops grow tall. People once believed that yellow flowers would cure *jaundice,* a yellowish discoloration of the body.

Many taboos come from homeopathic magic. People avoid certain harmless things because they resemble various harmful things. Among the Inuit (Eskimos), for example, parents have traditionally warned their sons against playing a string game, such as *cat's cradle,* in which children loop string around their fingers. They feared that playing such games might cause the children's fingers to become tangled in the harpoon lines they will use as adults.

Ray Manley, Shostal

A witch doctor is an important member of many African communities. Witch doctors perform magical ceremonies to heal the sick and protect people from harm.

Contagious magic comes from the belief that after a person has had contact with certain things, they will continue to influence that person. The most common examples of contagious magic involve parts of the body that have been removed, such as fingernails, hair, and teeth. A person's nails and hair supposedly can affect the rest of that person's body long after they have been cut off. A person can injure an enemy by damaging a lock of hair or a piece of clothing from the victim. A magician can even cripple an enemy by placing a sharp object in that person's footprint.

People who believe in contagious magic fear that an enemy can gain power over them by obtaining parts of their body. Therefore, they carefully dispose of their nails, hair, teeth, and even their body wastes.

Witches and voodoo magicians often practice a type of homeopathic magic called *envoûtement.* The magician makes a doll or some other likeness of an enemy. The magician harms the enemy by sticking pins into the doll or injuring it in some other way. In some societies, the doll includes a lock of hair or a piece of clothing from the enemy. This type of envoûtement is a combination of homeopathic and contagious magic.

Why people believe in magic

People turn to magic chiefly as a form of insurance—that is, they use it along with actions that actually bring results. For example, hunters may use a hunting charm. But they also use their hunting skills and knowledge of animals. The charm may give hunters the extra confidence they need to hunt even more successfully than they would without it. If they shoot a lot of game, they credit the charm for their success. Many events occur naturally without magic. Crops grow without it, and sick people get well without it. But if people use magic to bring a good harvest or to cure a patient, they may believe the magic was responsible.

People also tend to forget magic's failures and to be impressed by its apparent successes. They may consider magic successful if it appears to work only 10 per cent of the time. Even when magic fails, people often explain the failure without doubting the power of the magic. They may say that the magician made a mistake in reciting the spell or that another magician cast a more powerful spell against the magician.

Many anthropologists believe that people have faith in magic because they feel a need to believe in it. People may turn to magic to reduce their fear and uncertainty if they feel they have no control over the outcome of a situation. For example, farmers use knowledge and skill when they plant their fields. But they know that weather, insects, or diseases might ruin the crops. So farmers in some societies may also plant a charm or perform a magic rite to ensure a good harvest.

History

Ancient times. The use of magic goes back at least as far as 50,000 B.C. About that time, prehistoric people buried cave bears, probably as a magic rite. Scientists believe that much prehistoric art had magical purposes. Hunters, for example, probably used cave paintings of animals in rites intended to help them hunt the animals.

Magic was important to the ancient Egyptians, who used amulets, magic figures, and rites. The ancient Greeks and Romans tried to tell the future from dreams. They also consulted priests called *oracles,* who interpreted advice from the gods (see **Oracle**).

According to one legend, the Three Wise Men who visited the baby Jesus were astrologers who located Him by magic use of the stars (see **Magi**). The Bible has many references to magic, sorcery, and witchcraft.

During the Middle Ages, nearly all Europeans believed in magic. The clergy considered magic sinful but believed in its power. The so-called science of *alchemy* included much magic (see **Alchemy**). Alchemists hoped to discover the *philosopher's stone,* a magic substance that could change iron, lead, and other metals into gold. They also sought the *elixir of life,* a miraculous substance that could cure disease and lengthen life.

Many men joined a secret brotherhood called the *Rosicrucians,* an early version of the present-day Rosicrucian Order. The Rosicrucians studied magic lore and devoted themselves to curing the sick and helping people in other ways. The Masons, another secret group, also had elements of magic in their rituals.

From the 1500's to the 1700's, belief in magic continued widespread. Even highly educated people believed in its power. The Swiss physician Philippus Paracelsus, for example, experimented with alchemy and believed in the power of talismans. Sir Isaac Newton,

Bettmann Archive

Tarot cards are used in fortunetelling. The cards above are from a French deck of the Middle Ages. The lovers card, *left,* usually indicates harmony. The strength card, showing a woman taming a lion, often stands for the power of gentleness.

the famous English astronomer and mathematician, studied alchemy. Thousands of persons were tried and executed as witches during this period.

Many forms of magic tried to predict the future. People believed a person's character could be described or the future foretold in various ways. These methods included studying the palm of a person's hand, facial features, or even the moles on a person's skin. Some people used *tarot cards,* a set of playing cards with special pictures, for fortunetelling.

After about 1600, advances in science gradually weakened people's belief in magic. But as late as the 1700's, the Italian magician Count Allesandro di Cagliostro won fame for his powers. Cagliostro traveled through Europe selling love potions and elixirs of life.

Magic today still plays an important role in the life of many ethnic groups. Even among modern peoples, magic has many followers with an interest in such subjects as astrology, fortunetelling, and witchcraft. For example, many people who have faith in astrology read their daily horoscope in a newspaper.

Countless people believe in superstitions that involve forms of magic. Some persons carry a fetish, such as a rabbit's foot or a lucky penny. They believe these articles have magic power to bring good luck. Homeopathic magic appears in the superstition that a newborn baby must be carried upstairs before it is carried down. This act supposedly guarantees that the child will rise in the world and have a successful life.

Magic also survives in much of today's advertising. The manufacturers of such products as gasolines and headache remedies boast of new, secret ingredients. Advertisements may indirectly suggest that a mouthwash or a toothpaste will magically transform an unpopular person into a popular one. Many people buy these and other products for the magic qualities suggested by such advertising. Alan Dundes

Magician is an entertainer who performs tricks that seem impossible. Magicians make audiences believe they can pluck dollar bills out of the air and change one orange into three. They appear to read people's thoughts and produce bowls of goldfish from a scarf. Magicians even seem to make people disappear.

Many people think a magician's hands move so quickly that the audience cannot follow the actions and see how tricks are performed. But the hand is not quicker than the eye. Most magicians avoid rapid hand movements because they know such motions confuse people and weaken the effect of the trick.

Magicians base their tricks upon a variety of techniques from science and the arts that they cleverly use to deceive the mind and eye. The magician creates a drama designed to create the illusion that impossible things are happening. Creating this illusion involves acting ability, skillful physical movements, and the basic principles of such fields as chemistry, optics, psychology, and physics. Magicians use carefully planned actions and words to distract the audience by centering its attention on the wrong place at the right time. In addition, the spectators do not know that a magician uses various secret devices.

Professional magicians perform on television, in theaters, comedy clubs, nightclubs, and restaurants. They frequently appear at trade shows, banquets, business sales meetings, and conventions. Many young people find magic a fascinating hobby, and some earn money by doing tricks at birthday parties and other gatherings. Young magicians can gain poise and self-confidence by performing before an audience. They also may develop mental alertness and skill in using their hands.

Kinds of magic

Magic includes a number of types of tricks. The most common kinds of magic are (1) sleight of hand, (2) close-up magic, (3) illusions, (4) escape magic, and (5) mentalist magic.

Sleight of hand, also called *conjuring, legerdemain,* and *prestidigitation,* requires especially skillful hand movements. The oldest known sleight-of-hand routine, which was performed in ancient Egypt and remains popular today, involves several small balls. The magician makes the balls appear, disappear, or change size while they are hidden under inverted cups or dishes. Gali Gali, a modern Egyptian magician, ended the trick by changing the balls into baby chicks. Paul Rosini, an American magician, turned the cups right side up and then poured out wine.

More varieties of sleight-of-hand tricks can be performed with a deck of cards than with any other objects. Cardini, a British magician, produced fans of cards at his fingertips. Then he made lighted cigarettes appear, followed by cigars and a pipe. Other magicians have used doves, handkerchiefs, clocks and watches, jewels, and lighted electric bulbs.

Close-up magic is performed with spectators close to the performer, sometimes surrounding the magician or at a table only a short distance away. In close-up magic, magicians work with cards, coins, sponges, and other small objects. For example, every time the magician Albert Goshman lifted a saltshaker, a silver coin appeared beneath it. Johnny Paul, another magician, borrowed a piece of paper currency from a spectator and put it at one end of the table. Then he made the money move across the table into his hand.

Illusions. Magicians called *illusionists* perform large-scale tricks with the aid of human assistants, animals, and elaborate equipment. One of the most famous illu-

Milbourne Christopher Collection

The "fantastic suitcase" was an amazing illusion developed by Robert-Houdin, a famous French magician of the 1800's. Robert-Houdin pulled birds, cages, hats, and pans from a thin suitcase. He ended the trick by lifting out his young son.

Ken Baker's Magicland (WORLD BOOK photos by Steinkamp/Ballogg)

One ball changes into two in this sleight-of-hand trick. The magician uses a rubber ball and a metal shell that fits over it, as shown in the first photo above. The spectators believe they see one actual ball. The next two photos show the magician secretly separating the shell from the ball. The magician then displays the shell and the ball as if they were really two balls.

sions is sawing a woman in half. In 1921, magician Horace Goldin placed his assistant in a wooden box with her head, hands, and feet extending out through holes. He then sawed through the box without harming the body. Harry Blackstone, Jr., a modern illusionist, performs the same illusion by placing a young lady on a thin table without any covering. He then saws through her with a huge electric buzz saw. Although a board placed beneath her is cleanly cut in half, the lady is unharmed.

The first great modern illusionist was Robert-Houdin, a French magician who performed in the mid-1800's. Robert-Houdin became known as the father of modern magic because he contributed so many new tricks. For example, he suspended his young son in the air horizontally, with the boy's arm resting on the top of an upright pole. Later, Adelaide Herrmann, a British illusionist, also performed this trick.

Houdini Museum, Niagara Falls, Ontario

Harry Houdini, an American magician, specialized in escaping from apparently impossible predicaments. In the water torture trick, *shown here,* he freed himself from a box filled with water.

The three best-known illusionists in the United States during the 1900's were probably Harry Blackstone, Harry Kellar, and Howard Thurston. Blackstone made a camel disappear. Kellar featured an illusion in which he made a cage containing a live canary disappear in full view of the audience. Thurston fired a pistol, and an automobile on the stage immediately vanished. Notable illusionists of the late 1900's and early 2000's have included David Copperfield, Lance Burton, and the team of Siegfried and Roy.

Escape magic. Some magicians specialize in making apparently impossible escapes from various predicaments. The most famous escape performer was Harry Houdini, an American, who freed himself from police handcuffs, leg irons, and locked jail cells. He also let himself be handcuffed and placed in a crate that was nailed shut and lowered into a river. Houdini escaped in a few seconds. See **Houdini, Harry.**

Mentalist magic. Some magicians, called *mentalists,* perform mind-reading tricks and predict future events. Mentalists call out the names of strangers in an audience and duplicate designs drawn on a piece of paper by spectators and then sealed in envelopes. They also write the correct total of numbers selected later by volunteers. During a television broadcast, Dunninger, a famous American mentalist, seemingly read the mind of a stranger in a submerged submarine.

Becoming a magician

People enjoy magic because of its mystery. If they know how a trick is done, it loses its appeal—and so magicians seldom reveal the secrets of their tricks. But basic methods can be learned from books on magic. Some of these books can be obtained from general bookstores or from public libraries. Other such books are sold by stores specializing in equipment for magicians.

Two organizations—the Society of American Magicians (S.A.M.) and the International Brotherhood of Magicians (I.B.M.)—have clubs in many cities throughout the world. Both groups have headquarters in St. Louis, Missouri. Each publishes a monthly magazine and holds an annual convention. At the annual convention, magicians give lectures and demonstrate new tricks, and dealers in magicians' supplies display new equipment.

Maginot Line, *MAZH uh noh,* is a fortified line of defense along the eastern border of France. It was constructed after World War I (1914-1918). Forts stand aboveground, flanked by pillboxes and barbed-wire entanglements. Underground chambers provide space for communications systems, hospitals, storerooms, garages, and living quarters for officers and people. In May 1940, the Germans invaded France through Belgium, passing north of the Maginot Line. In three weeks, they swept past and then behind the line. Today, some of the forts on the Maginot Line are tourist attractions.

Magna Carta, *MAG nuh KAHR tuh,* is a document that marked a decisive step forward in the development of constitutional government and legal ideas in England. In later centuries, much of the rest of the world also benefited from it because many countries followed English models in creating their own governments. These countries include the United States and Canada. The Latin words *Magna Carta* mean *Great Charter.*

English barons forced King John to approve the charter in June 1215 at Runnymede, southwest of London. In the charter, the king granted many rights to the English aristocracy. The ordinary English people gained little. But many years later, Magna Carta became a model for those who demanded democratic government and individual rights for all. In its own time, the greatest value of Magna Carta was that it limited royal power and made it clear that even the king had to obey the law.

Reasons for the charter. From the Norman invasion of England in 1066 through the 1100's, most of the kings who ruled England were able and strong. They usually tried to govern justly and respected feudal law. Under feudal law, nobles called *barons* received land in return for military and other services to the king. Law and custom established the barons' duties and what was expected of the king. But there was no actual control over the king's power. When John became king in 1199, he exercised his power even more forcefully than earlier kings. He demanded more military service than they did. He sold royal positions to the highest bidders. He demanded larger amounts of money without consulting the barons, which was contrary to feudal custom. He decided cases according to his wishes, and people who lost cases in his court had to pay crushing penalties.

English barons and church leaders began to express dissatisfaction with John's rule early in his reign. Their unhappiness grew when he lost most of the English possessions in France in warfare lasting from 1202 to 1206. In 1213, a group met at St. Albans, near London, and drew up a list of demands based in part on the coronation charter of Henry I, who had been king from 1100 to 1135. After John lost an important battle against France at Bouvines (in what is now western Belgium) in 1214, civil war broke out in England. John saw that he could not defeat his opponents' army, and so he agreed to a set of articles on June 15, 1215. Four days later, the articles were *engrossed* (written out in legal form) as a royal charter. Copies of the charter were distributed throughout the kingdom.

Promises in the charter. Magna Carta contained 63 articles, most of which pledged the king to uphold feudal customs. These articles chiefly benefited the barons and other landholders. One article granted the church freedom from royal interference. A few articles guaranteed rights to residents of towns. Ordinary free people and peasants were hardly mentioned in the charter, even though they made up by far the largest part of England's population.

Some articles that in 1215 applied only to feudal landholders later became important to all the people. For example, the charter stated that the king could make no special demands for money without the consent of the barons. Later, this provision was used to support the argument that no tax should be raised without the consent of Parliament.

Still other articles became foundations for modern justice. One article says that the king will not sell, deny, or delay justice. Another says that no freeman shall be imprisoned, deprived of property, exiled, or destroyed, except by the lawful judgment of his *peers* (equals) or by the law of the land. The idea of due process of law, including trial by jury, developed from these articles. In John's time, however, there was no such thing as trial by jury in criminal cases.

The charter tried to make the king keep his promises by establishing a council of barons. If the king violated the charter and ignored warnings of the council, it could raise an army to force the king to live by the charter's provisions. But these measures were unsuccessful.

The charter after 1215. Magna Carta did not end the struggle between John and the barons. Neither side intended to abide by the charter completely. Pope Innocent III canceled the charter at the king's request, and war broke out immediately. After John's death in 1216, however, his son Henry III and later English kings promised to abide by the charter. The most famous of these promises was that of Edward I in 1297. Through these promises, the charter came to be recognized as part of the fundamental law of England.

In the 1600's, members of parliament used Magna Carta to rally support in their struggle against the strong rule of the Stuart kings. These lawmakers came to view the charter as a constitutional check on royal power. They cited it as a legal support for the argument that there could be no laws or taxation without the consent of Parliament. These members of Parliament used the charter to demand guarantees of trial by jury, safeguards against unfair imprisonment, and other rights.

In the 1700's, Sir William Blackstone, a famous lawyer, set down these ideals as legal rights of the people in his famous *Commentaries on the Laws of England* (see **Blackstone, Sir William**). Also in the 1700's, colonists carried these English ideals on legal and political rights to America. The ideals eventually became part of the framework of the Constitution of the United States.

Four originals of the 1215 charter remain. Two are in the British Library in London, one in Salisbury Cathedral, and one in Lincoln Cathedral. For many years, the document was commonly known as *Magna Charta.* But in

1946, the British government officially adopted the Latin spelling, *Magna Carta.* Emily Zack Tabuteau

Holt, James C. *Magna Carta.* 2nd ed. Cambridge, 1992.
Pallister, Anne. *Magna Carta.* Oxford, 1971.
Turner, Ralph V. *King John.* Longman, 1994. Includes background on the origins of Magna Carta.

Magnesia, *mag NEE shuh* or *mag NEE zhuh,* is a white, tasteless substance. It is a chemical compound made up of magnesium and oxygen and is also called *magnesium oxide.* A form of magnesia is used in medicines to aid digestion. Manufacturers also use magnesia in refining metals from their ores and in making crucibles, insulating material, and special cements.

After magnesia is swallowed, it is converted by water in the digestive system to *magnesium hydroxide.* Magnesium hydroxide is a good antacid because it neutralizes excess stomach acid without releasing carbon dioxide. This property also makes it a good antidote against poisoning by acids. In acid poisoning, a build-up of gas in the stomach may cause a rupture. Doctors may also recommend *milk of magnesia,* a mixture of water and magnesium hydroxide, as a laxative. Barbara M. Bayer

Magnesium, *mag NEE shee uhm* or *mag NEE zhee uhm,* a silver-white metal, is the lightest metal that is strong enough to use in construction. It weighs only about two-thirds as much as aluminum, another widely used light metal. Magnesium was discovered in 1808 by the English chemist Sir Humphry Davy.

Magnesium is a fairly abundant metallic element. But pure magnesium does not occur in nature. Various minerals contain magnesium compounds. A few of these compounds, primarily magnesium chloride and magnesium sulfate, occur in dissolved form in seawater and in some pools of underground water. Seawater contains 0.13 percent magnesium and provides a practically unlimited source of the metal. Magnesium occurs in the minerals magnesite, brucite, and dolomite, as well as in amphibole asbestos, olivine, serpentine, talc, and in certain of the other silicate minerals (see **Silicate**).

Magnesium plays a vital role in the life processes of plants and animals. Chlorophyll, which green plants use in photosynthesis, contains magnesium. Plants produce carbohydrates, a class of foods essential to living things, by means of photosynthesis. Magnesium also takes part in the duplication of substances called DNA and RNA, which have a key part in determining the heredity of all organisms (see **Heredity** [The flow of genetic information]). Magnesium also activates many of the enzymes that speed up chemical reactions in the human body.

Uses. Magnesium and its alloys are used in manufacturing many products. Their light weight makes them suitable for aircraft and automobile parts and for tools and equipment. Most magnesium alloys contain aluminum and zinc. These materials make magnesium alloys stronger and easier to shape. Some alloys may also contain small amounts of such elements as manganese, thorium, and zirconium that provide other properties.

Magnesium is used for a variety of nonstructural purposes because it is extremely active chemically. For example, pieces of magnesium are placed next to buried steel pipelines and water tanks. If magnesium were not present, oxygen and other chemicals in the earth would corrode the steel. Instead, the magnesium reacts with the chemicals. The pieces of magnesium can easily be replaced periodically at a cost much lower than that of replacing or repairing the steel. Protective strips of magnesium are also attached to the hulls of ships.

Steel manufacturers add magnesium to steel to remove sulfur and other impurities. In addition, magnesium is used in fireworks and flares because it burns with a brilliant white light. It also produces intense heat when it burns, making it useful for incendiary bombs.

Magnesium combines with other elements to form many useful compounds. These compounds include two commonly used medicines—milk of magnesia and Epsom salt (see **Magnesia**). Magnesium oxide resists heat and is used to line special types of furnaces. Also, magnesium oxide forms on the surface of magnesium metal and prevents it from corroding readily at low temperatures. If it were not for this protective layer, magnesium would not be a suitable structural material. Magnesium chloride is an important *catalyst* (substance that speeds up a chemical reaction) in the preparation of organic compounds. Other magnesium compounds are used in tanning leather; in dyeing textiles; and in making cement, fertilizer, and insulating materials.

Properties. Magnesium's chemical symbol is Mg. The metal belongs to the group of elements called *alkaline earth metals* (see **Element, Chemical** [Periodic table of the elements]). It has a density of 1.738 grams per cubic centimeter at 20 °C. Its atomic number is 12, and its atomic weight is 24.3050. Magnesium melts at 650 °C and boils at 1090 °C.

Magnesium never occurs in nature as a pure metal because it is so active chemically. It readily combines with most acids and with many nonmetals, including nitrogen. When heated with the salts or oxides of many metals, magnesium replaces the other metal. In this process, called *reduction,* the magnesium purifies the other metal, preparing it for various uses.

How magnesium is obtained. Much of the magnesium used in the United States is recovered from seawater by the *Dow process.* In this process, lime obtained from the rock dolomite is mixed with seawater, which contains magnesium chloride. The lime and the magnesium chloride react to form magnesium hydroxide and calcium chloride. The magnesium hydroxide separates from the rest of the mixture. It is filtered out and mixed with hydrochloric acid, forming magnesium chloride and water. The water evaporates, leaving highly concentrated magnesium chloride, which is melted by being heated to a temperature above 708 °C. Then an electric current is passed through the melted compound. This kind of process is called *electrolysis* (see **Electrolysis**). The current changes the magnesium chloride into magnesium and chlorine gas. The molten magnesium is poured off and cast into forms called *ingots.*

A less widely used method of refining magnesium is known as the *ferrosilicon process* or *Pidgeon process.* This method, used primarily in Canada, involves heating dolomite in a vacuum with an alloy consisting of silicon and iron. The magnesium in the dolomite vaporizes, and then it condenses as crystals. The magnesium crystals are melted and cast into ingots. Emily Jane Rose

Magnetic amplifier, also called a *saturable reactor,* is a device used to control large amounts of electric power. It is used where currents are too large, or other conditions are too severe, for transistor or vacuum tube amplifiers. For example, magnetic amplifiers are often used to control the speed of large motors or the brightness of airport runway lights.

A magnetic amplifier consists of two coils of wire—a *main coil* and a *control coil*—wound around an iron core. An alternating current flows through the main coil and creates a changing magnetic field around the core. This changing field limits the amount of current that can flow. But if direct current is passed through the control coil, the core becomes *saturated* (completely magnetized). The saturation cancels the limiting effect of the changing field, and enables much more current to flow through the main coil. Glenn A. Burdick

Magnetic equator is an imaginary band that circles the earth near the geographic equator. The earth acts like a huge bar magnet whose poles lie close to the north and south geographic poles. The straight line between the poles of this imaginary magnet is called the *geomagnetic axis.* The magnetic equator lies on a plane that is at right angles to the geomagnetic axis.

An instrument called a *dipping needle* indicates the direction of the earth's magnetic equator. A dipping needle is a magnetized needle mounted on a horizontal pivot so that it can swing up and down freely. At any point on the magnetic equator, the needle is horizontal. North of the magnetic equator, the north tip of the needle points downward. South of the magnetic equator, this tip points upward. William C. Mahaney

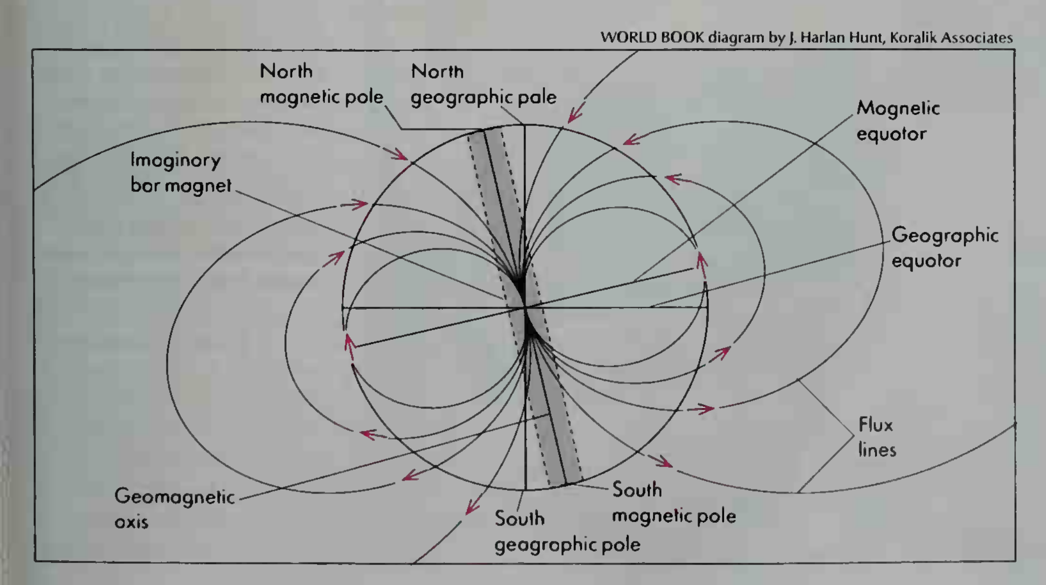
Magnetic field. See Magnetism.

Magnetic levitation train, also called *maglev train,* is a vehicle that uses magnetic forces to travel at high speeds. Maglev trains float above a fixed track called a *guideway,* but do not touch the track. A maglev train's speed is not limited by the friction or vibration that contact with a track would cause. Maglev trains have exceeded 340 miles (550 kilometers) per hour on test tracks.

Maglev trains have several advantages over other high-speed trains. For example, they can reach higher speeds and operate more quietly. Their guideways need little maintenance. In addition, maglev trains use electric power and therefore produce little pollution themselves.

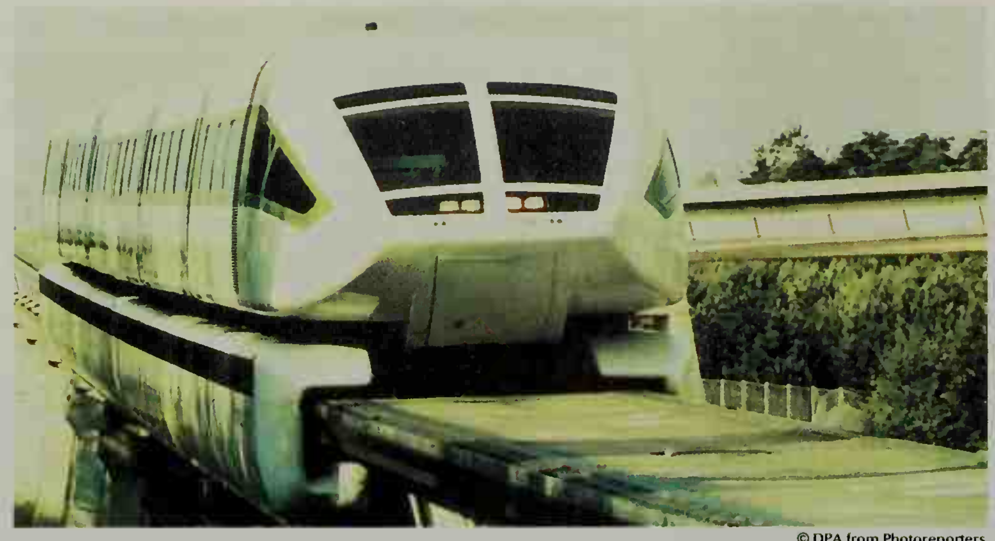
There are two kinds of maglev technology—*electrodynamic* and *electromagnetic.* Electrodynamic maglev uses magnetic *repulsion* (pushing away) to make the train float. Electromagnetic maglev uses magnetic attraction.

Electrodynamic maglev was invented in the early 1960's by the nuclear engineer James R. Powell and the physicist Gordon T. Danby of the United States. Since then, Japanese researchers have developed full-sized test models that can reach speeds over 340 miles (550 kilometers) per hour. Electrodynamic maglev trains use superconducting magnets—that is, magnets that are cooled to extremely cold temperatures and so conduct electric current without resistance. The magnets are placed on the bottom of the train. As the train moves, the magnets *induce* (create) currents in wire coils or metal sheets that are set in the guideway. The opposing magnetic force between the magnets and the induced currents lifts the vehicle. The train runs on wheels until it gains enough speed to lift off the guideway. It travels about 4 inches (10 centimeters) above the guideway.



Separate electric currents pass through other coils in the guideway. The currents produce a magnetic field that travels along the guideway and pushes the maglev train forward, much as an ocean wave pushes a surfer. The speed of the maglev train remains constant as the magnetic force adjusts, even during travel uphill or downhill.

Electromagnetic maglev was developed by a group of West German companies, beginning in the early 1970's. The Germans have tested full-sized trains that run as fast as 310 miles (500 kilometers) per hour.



The underside of an electromagnetic maglev train carries electromagnets that ride beneath a T-shaped guideway. When current flows through the magnets, they are attracted upward to steel rails on the guideway. Currents flowing in wires in the steel rails create a shifting magnetic field that pushes the train forward.

An electromagnetic maglev train that uses conventional magnets travels only about $\frac{3}{8}$ inch (1 centimeter) above the track. To prevent the magnets from hitting the guideway, the lifting current must continually be adjusted by a fast-acting control system. Scientists have designed an electromagnetic maglev train that would use

WORLD BOOK diagram by J. Harlan Hunt, Koralik Associates

The magnetic equator is at right angles to the earth's *geomagnetic axis,* the straight line between the north and south magnetic poles. The earth's magnetic field, shown by imaginary *flux lines,* is shaped as if the earth were a bar magnet. The arrows show how a compass needle that can swing up and down aligns itself with this field.

A maglev train floats above a fixed track but does not touch it. Maglev trains like this one are lifted into the air when magnets that ride beneath the track are attracted upward to iron rails in the underside of the track.

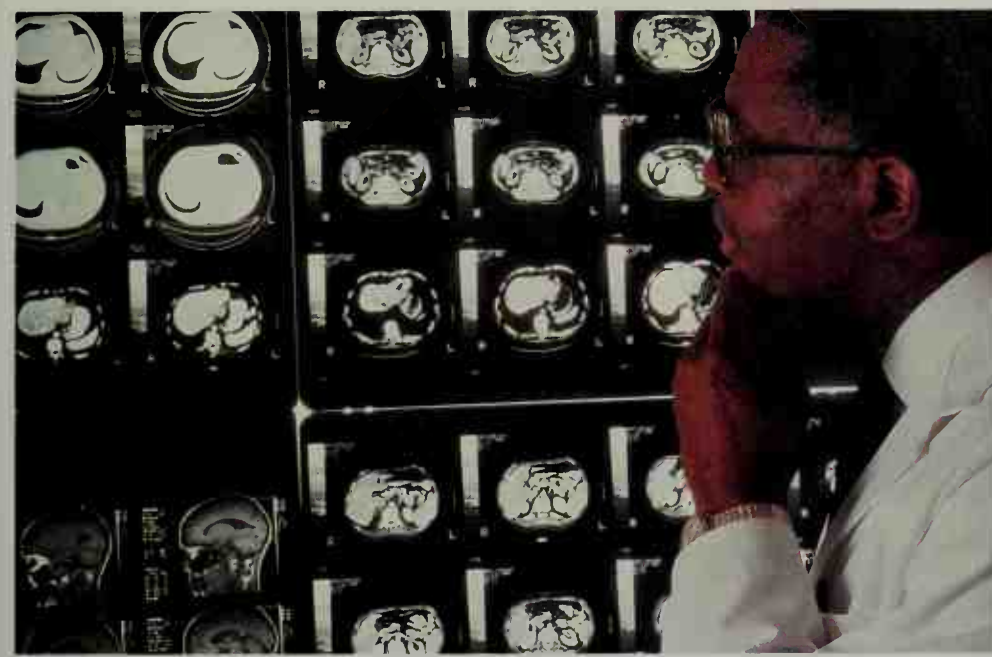
Magnetic resonance imaging (MRI) is a technique used in medicine to produce images of tissues inside the body. Physicians use these images to diagnose certain diseases, disorders, and injuries in their patients.



MRI is an important diagnostic tool because it enables physicians to identify abnormal tissue without opening the body through surgery. MRI does not expose the patient to radiation, unlike tests that use X rays. Also, MRI lets physicians see through bones and organs. MRI is safe for most people. But MRI uses a pow-

Siemens Medical Systems

Magnetic resonance imaging is used in medicine. The patient is placed inside a machine that has a huge magnet. The magnetic field causes the nuclei of certain atoms inside the body to line up. The machine then sends out a radio signal, which causes the nuclei to change direction. The changes create signals that a computer translates to produce detailed cross-sectional images on a video screen.

A doctor studies images produced by MRI. Physicians use MRI to identify abnormal tissue inside the body without performing surgery. It is most often used to study the head or spine.

Superstock

erful magnet and so cannot be used on people with metal implants, such as pacemakers or artificial joints.

An MRI unit consists mainly of a large cylindrical magnet, devices for transmitting and receiving radio waves, and a computer. During the examination, a magnetic field is applied to the patient's body. The magnetic field causes nuclei in certain atoms inside the body to line up. Radio waves are then directed at the nuclei. If the frequency of the radio waves equals that of the atom, a *resonance condition* is produced. This condition enables the nuclei to absorb the energy of the radio waves. When the radio-wave stimulation stops, the nuclei return to their original state and emit energy in the form of weak radio signals. The strength and length of these signals—and therefore the kind of image produced—depend on various properties of the tissue. A computer translates the signals into highly detailed cross-sectional images.

An MRI examination is supervised by a *radiologist*—a physician trained in using images for medical diagnosis. The technique is most often used to study the head or spine. MRI is also used to detect tumors and other abnormalities in the chest, abdomen, and joints. Scientists also use a type of MRI called *functional MRI (fMRI)* to study brain activity during mental or physical tasks.

MRI devices are extremely costly and must be housed in special facilities. As a result, they are found chiefly in large medical centers. In some parts of the United States, several small hospitals share a mobile MRI unit.

MRI technology developed from a related technique called *nuclear magnetic resonance (NMR) spectroscopy.* Scientists use NMR spectroscopy to obtain detailed information about molecular structure. Glenn Forbes

Magnetic storm is a strong fluctuation in the earth's magnetic field. A magnetic storm is caused by high-energy particles and intense radiation given off by the sun as a result of solar activity. The overall level of magnetic storm activity varies with the recurring 11-year *sunspot cycle* (see **Sun** [Magnetic field]). It also varies with the 27-day period of the sun's rotation, as different active regions of the sun face the earth.

Many magnetic storms are associated with *coronal holes,* which are regions of low density in the sun's corona. A continuous flow of electrically charged particles from the sun called the *solar wind* emerges chiefly from the coronal holes. High-speed streams of the solar wind appear as the sun's activity increases. When the rapidly moving particles of these streams strike the earth's magnetic field, some of the particles are trapped by the field. The interaction of these particles with the earth's magnetic field produces a magnetic storm.

The solar wind is separated into large regions of either positive or negative magnetic polarity. A magnetic storm occurs when a boundary between such regions of opposite polarity is swept past the earth by the sun's rotation. The passage of these boundaries is the solar phenomenon most closely linked to magnetic storms.

Scientists believe many *solar flares,* which are eruptions on the sun's surface, also cause magnetic storms. Such storms start abruptly, unlike those associated with the solar wind, which begin gradually. Solar flares emit high-energy electrons and protons as well as radiation in the form of gamma rays and X rays. The electrons and protons are trapped by the earth's magnetic field. The gamma rays and X rays affect the field by causing changes in the ionosphere and in the *Van Allen belts,* which are doughnut-shaped regions of charged particles that surround the earth.

Magnetic storms demonstrate how solar activity directly affects the earth. They cause disturbances in the ionosphere, which interfere with short-wave radio reception. Scientists detect magnetic storms by means of such interference. In addition, abrupt changes in the earth's magnetic field resulting from magnetic storms can cause surges in power transmission lines. Magnetic storms are also accompanied by auroras.

The sun's increased magnetic field not only causes magnetic storms but also shields the earth from high-energy cosmic rays that originate in outer space. The resulting decrease in cosmic rays bombarding the earth is called the *Forbush effect.* Jay M. Pasachoff

Magnetism causes a horseshoe magnet to attract paper clips, *top left,* and enables industrial magnets to lift heavy loads of scrap metal, *top right.* Magnets are also used in scientific devices. Physicists use magnets to boost atomic particles to high speeds in a particle accelerator, *above.*

Magnetism

Magnetism is the force that electric currents exert on other electric currents. Magnetism may be created by the motion of electrons in the atoms of certain materials, which are called magnets. Magnetic force may also be produced by ordinary electric current flowing through a coil of wire, called an *electromagnet.* The magnetic force may cause *attraction* or *repulsion*—that is, it may pull magnets together or push them apart.

The contributors of this article are Richard B. Frankel, Professor of Physics at California Polytechnic State University; and Brian B. Schwartz, Professor of Physics at Brooklyn College and Associate Executive Secretary and Education Officer of the American Physical Society.

Magnets have many different shapes. The most common are bars and thick disks, squares, or rectangles. A horseshoe magnet is a bar magnet bent into a U shape.

Magnets have a wide variety of uses. Magnets stick to certain metals, which makes them useful as fasteners and latches. Electric tools, appliances, and trains require magnets to run because all electric motors basically consist of a rotating electrical conductor situated between the poles of a stationary magnet. Huge magnets move iron and steel scrap. Tiny magnets on audiotape and videotape store sound and images. Magnets in telephones, radios, and TV sets help change electrical impulses into sounds. Scientists use powerful magnets to hold extremely hot gases in nuclear energy research.

Some rocks, minerals, and meteorites are natural magnets. The earth itself is a giant magnet, and so are the sun and other stars and most of the planets. Some

insects, birds, and fish have extremely small magnets in their bodies. Biologists think these magnets may help animals find their way when migrating.

People in ancient Greece and China independently discovered magnetism when they found that the mineral magnetite attracted iron. Scientists could not explain what caused magnetism, however, until the mid-1800's.

What magnets do

Magnetic poles. A magnet with two poles, such as a bar magnet, is called a *magnetic dipole.* (The prefix *di-* means *two.*) If a bar magnet is hung by a string tied around its middle, it rotates until one end points north and the other end points south. The end that points north is called the *north pole,* and the south-pointing end is the *south pole.* In a disk or other flat magnet, the flat surfaces are the poles. If a magnet is broken or cut in half, each piece has a north and south magnetic pole.

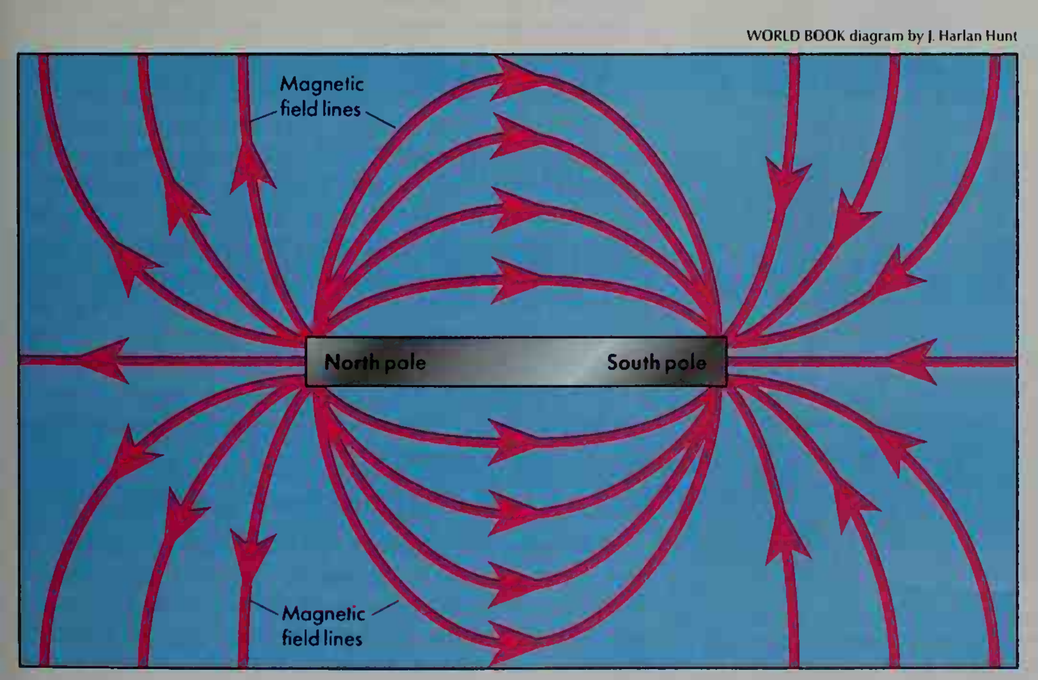
Attraction and repulsion. Magnetism causes unlike magnetic poles to attract each other but like poles to *repel* (push away from) each other. If the north pole of a magnet is brought near the south pole of another magnet, the magnetic force pulls the magnets together. But two north poles or two south poles repel each other. If a bar magnet is suspended between the ends of a horseshoe magnet, it will move so that its north pole faces away from the horseshoe magnet's north pole.

Magnetic fields. The region around a magnet where the force of magnetism can be felt is said to contain a *magnetic field.* A magnetic field is invisible. You can picture the magnetic field of a bar magnet, however, if you place a piece of paper over the magnet and sprinkle iron filings on the paper. The filings bunch together near the poles and form a pattern around the magnet that corresponds to its magnetic field. A magnetic field can also be thought of as a set of imaginary lines called *field lines, flux lines,* or *lines of force.* We think of these lines going out from the north pole of a magnet, looping around, and returning to the magnet at its south pole. The lines lie closest to each other near the poles, where the magnetic field is strongest.

A magnetic field exerts a force on nearby magnets to make them align along its field lines. The needle of a magnetic compass, for example, is actually a slender bar magnet. It normally points north along one of the earth's magnetic field lines. But a strong bar magnet placed next to the compass will cause the needle to point along one of the bar magnet's field lines.

The strength of a magnetic field is measured in units called *gauss* or *tesla.* One tesla equals 10,000 gauss. The earth's magnetic field at its surface is about $\frac{1}{2}$ gauss. The field near the poles of a small horseshoe magnet may be several hundred gauss. Fields of magnets used in industry may measure more than 20,000 gauss (2 tesla).

Magnetization. A magnet attracts iron, steel, nickel, and certain other materials. The attracted materials then become magnets themselves in a process called *magnetization.* A steel nail placed near a magnet, for example, becomes magnetized and can attract a second nail. Magnetization occurs because the magnet causes spinning particles called *electrons* in the atoms of the nail to align along the magnet's field lines. The atoms with aligned electrons then act like tiny bar magnets.



Kinds of magnets

Most objects made of aluminum, concrete, copper, cotton, glass, gold, paper, plastic, rubber, silver, and wood are *nonmagnetic materials.* Magnets neither repel nor attract these substances, and magnetic fields pass through them without weakening. But other materials, called *magnetic materials,* become magnetized when exposed to a magnetic field. Magnetic materials are used in making temporary and permanent magnets. An electromagnet is produced by an electric current.

Temporary magnets are made of such materials as iron and nickel. These materials are known as *soft magnetic materials* because they usually do not retain their magnetism outside a strong magnetic field. A magnetized iron nail, for example, loses its magnetism if it is removed from a magnetic field.

Permanent magnets keep their magnetism after they have been magnetized. For this reason, they are

WORLD BOOK diagram by J. Harlan Hunt

A magnetic field can be shown as imaginary lines that flow out of the north pole and into the south pole of a magnet. The magnetic field of a bar magnet, *left,* is strongest near the magnet's poles, where the lines lie closest to each other.

known as *hard magnetic materials.* Many strong permanent magnets are *alloys* (mixtures) of iron, nickel, or cobalt with other elements. These magnetic alloys include Alnico, a group of alloys usually containing a mixture of aluminum, nickel, cobalt, iron, and copper; and an alloy of cobalt and chromium called cobalt-chromium. Alloys containing metallic elements called *rare-earth elements* have produced some of the strongest permanent magnets. These alloys include samarium-cobalt, a mixture of cobalt and the rare-earth element samarium; and a combination of boron, iron, and the rare-earth element neodymium. Another important group of magnetic alloys, called *ferrites,* consist of iron, oxygen, and other elements. The best-known natural permanent magnet is a ferrite known as *magnetite* or *lodestone* (also spelled *loadstone*).

Some soft magnetic materials can be made into weak permanent magnets. An iron needle for a compass, for example, can be permanently magnetized by stroking it in one direction with a magnet.

Electromagnets are temporary magnets produced by electric currents. The simplest electromagnets consist of electric current flowing through a cylindrical coil of wire called a *solenoid.* One end of the solenoid becomes the north pole of the electromagnet, while the other end becomes the south pole. The poles switch position if the direction of the current is reversed. If the current is shut off, the solenoid loses its magnetism.

Many electromagnets have a cylinder of soft magnetic material, such as iron, within a coil of wire to strengthen the magnetic field the electromagnet produces. When current passes through the coil, the cylinder becomes strongly magnetized. The cylinder loses its magnetism, however, when the current is shut off. This characteristic of electromagnets makes them useful as switches in electric doorbells and telegraphs.

The strength of an electromagnet depends on the number of windings in the coil and the strength of the electric current. More windings and stronger current produce more intense magnetic fields. Fields of about 250,000 gauss (25 tesla) have been produced by passing extremely strong electric current through a coil made of copper plates. These magnets require cooling systems that pump water past the coils, however, to prevent the heat produced by the current from melting the copper plates. Some electromagnets, called *superconducting magnets,* use coils that conduct current with no loss of energy and, thus, do not heat up. The strongest electromagnets, called *hybrid magnets,* consist of a water-cooled electromagnet within a superconducting magnet. These devices can produce magnetic fields of about 350,000 gauss (35 tesla).

Francis Bitter National Magnet Laboratory, M.I.T

Technicians assemble a hybrid magnet by lowering an electromagnet into a superconducting magnet. Hybrid magnets can produce extremely strong fields of about 350,000 gauss.

Artstreet

Magnetite, also called *lodestone,* is a natural magnet that attracts iron nails and certain other metals. It belongs to an important group of magnetic materials called *ferrites.*

Uses of magnets and magnetism

In homes, the attractive force between magnets makes them useful as latches on cabinet doors, as knife racks, and as fasteners for holding papers on refrigerators. The most important use of magnets in the home, however, is in electric motors. All electric motors use

electromagnets or a combination of electromagnets and permanent magnets. These motors run refrigerators, vacuum cleaners, washing machines, compact disc players, blenders, hedge trimmers, drills, sanders, and such toys as electric trains, race cars, and robots.

Audiotape and videotape players have electromagnets called *heads* that record and read information on tapes covered with many tiny magnetic particles. The magnetic field of a recording head makes the magnetic particles on the tape form patterns that another type of head can read. The second head transforms the magnetic patterns into an electric signal. Magnets in speakers transform the signal into sound by making the speakers vibrate. An electromagnet called a *deflection yoke* in TV picture tubes helps form images on a screen.

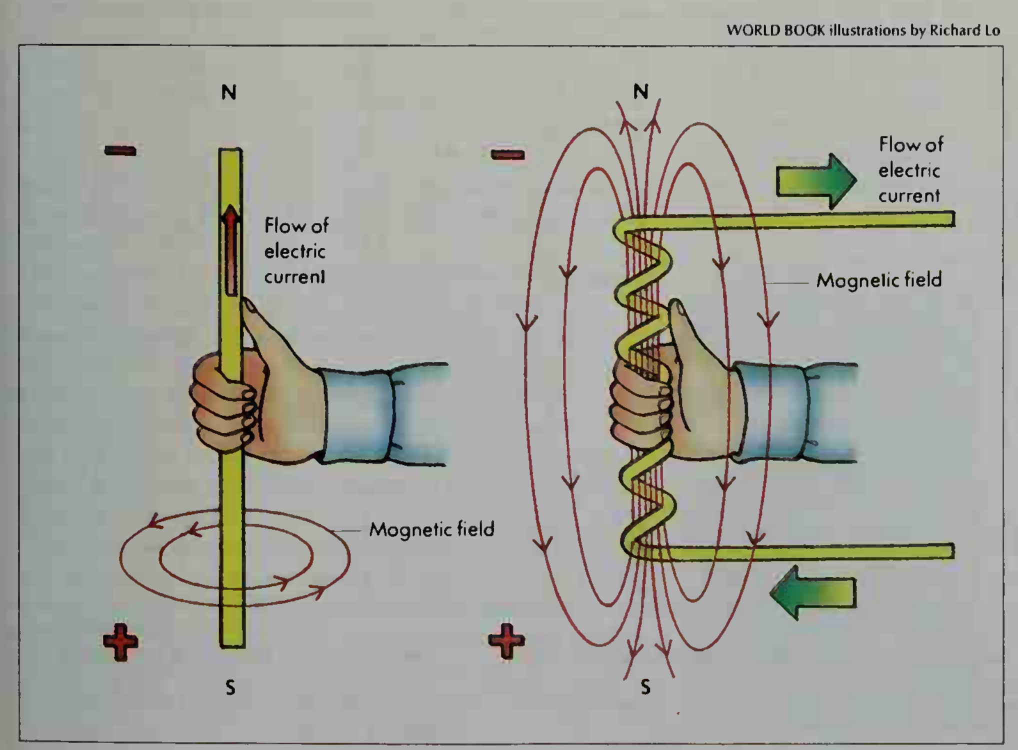
In industry and business, magnets in electric motors help run almost any machine that makes something move or rotate. These devices include cranes, cutters, electric typewriters, fax machines, machine tools, photocopiers, and printing presses. Magnets in computers store information on magnetic tapes and disks. Powerful electromagnets attached to cranes move scrap iron and steel and separate metals for recycling.

One of the most important uses of magnets is electric power production. Generators in power plants rely on magnets similar to those in electric motors to produce electricity. Devices called *transformers* use electromagnets to change the high-voltage electricity carried by power lines to the lower voltage needed in homes and businesses.

In transportation. All electrified transportation systems depend on magnets in electric motors. These systems include trains, subways, trolleys, monorails, cable cars, escalators, elevators, and moving sidewalks. Electric motors operate windshield wipers, electric windows and doors, door locks, and other devices in automobiles, buses, and airplanes. Electromagnets also produce radio waves in radar systems, an important navigation aid for ships and airplanes.

Scientists and engineers have developed trains that use electromagnets to *levitate* (float) above a track without touching it. These trains, called *magnetic levitation* or *maglev* trains, eliminate the friction of wheels on the track and thus can move at much higher speeds than ordinary trains do.

In science and medicine. Magnets and magnetic fields are widely used in scientific research. Electromagnets in electron microscopes focus a beam of electrons on a sample to be studied. Powerful magnets called *bending magnets* help control beams of atomic particles that have been boosted to high speed in devices called *particle accelerators.* In nuclear energy research, physicists make the nuclei of atoms *fuse* (unite) in extremely hot gases called *plasmas.* The plasmas are so hot they would melt the walls of any container made of ordinary materials. Therefore, physicists hold the plasmas away from the container's walls in a strong magnetic field that functions as a "magnetic bottle."



In medicine, many devices for diagnosing diseases use magnets. In a technique known as *magnetic resonance imaging* (MRI), the patient lies inside a large cylindrical magnet. MRI uses magnetic fields and radio waves to produce images of the head, spine, internal organs, and other body parts. Other diagnostic devices enable physicians to observe magnetic fields generated by the brain, heart, and other internal organs.

How magnetism works

Magnetism and electricity are closely related. Together, they make a force called *electromagnetism,* one of the basic forces in the universe. A moving magnet near a coil of copper wire, for example, can *induce* (produce) an electric current in the coil. Similarly, an electric current flowing through a wire creates a magnetic field around the wire.

The direction of the magnetic field around a straight wire can be determined according to the *right-hand rule.* If the thumb of the right hand points along the flow

WORLD BOOK illustrations by Richard Lo

The right-hand rule shows the direction of the magnetic field around a wire that carries an electric current. If the thumb of the right hand points along the flow of current in a straight wire, *far left,* the fingers curl around the wire in the direction of the field. If a wire carrying current is wound into a coil, the magnetic field is strengthened. Such a coil is called a *solenoid.* The direction of the magnetic field surrounding a solenoid, *left,* can be found by wrapping the fingers around the coil in the direction of the current. The thumb then points to the solenoid's north pole and shows the direction of the field.

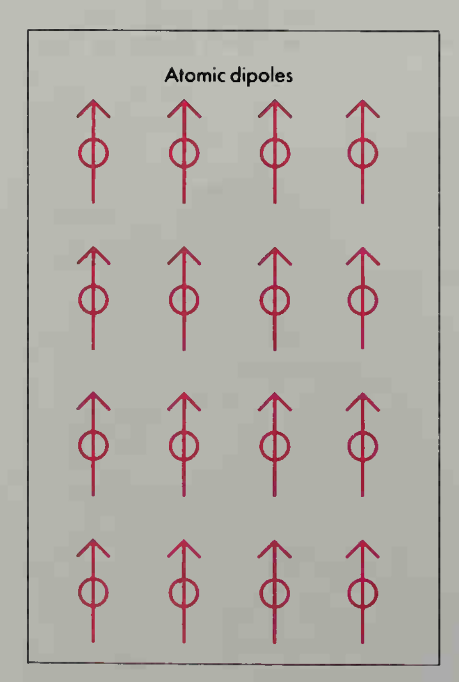
of current, the fingers curl around the wire in the direction of the magnetic field.

The right-hand rule also applies to the magnetic field produced by a coil or solenoid. Magnetic field lines flow through the length of a coil. If the fingers of the right hand curl around the coil in the direction of the current, the right thumb points to the coil's north pole and shows the direction of the magnetic field lines.

The right-hand rule is used when the current is thought of as a flow of positive electric charges. In a simple electric circuit connected to a battery, for example, the current is defined as flowing from the battery's positive terminal to its negative terminal.

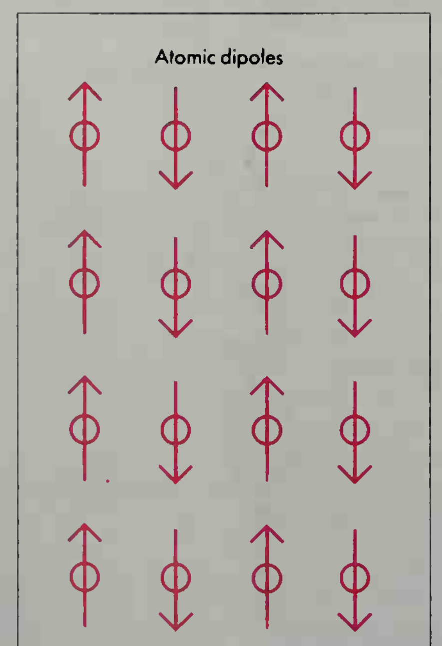
Magnetism in atoms. Atoms have a small, dense center called a *nucleus* surrounded by one or more lighter, negatively charged electrons. Nuclei consist of *protons,* which have positive charges, and *neutrons,* which have no charge. Under most conditions, the atoms of each element contain an equal number of protons and electrons, and so the atoms are electrically neutral.

The relationship between magnetism and electricity also operates in the atom. The motion of negatively charged electrons around a nucleus makes an electric current, which produces a magnetic field. However, the effect of the electrons moving in one direction equals the effect of the electrons moving in the opposite direction. As a result, the magnetic fields of the moving electrons cancel each other out, and the atom has no magnetic field.



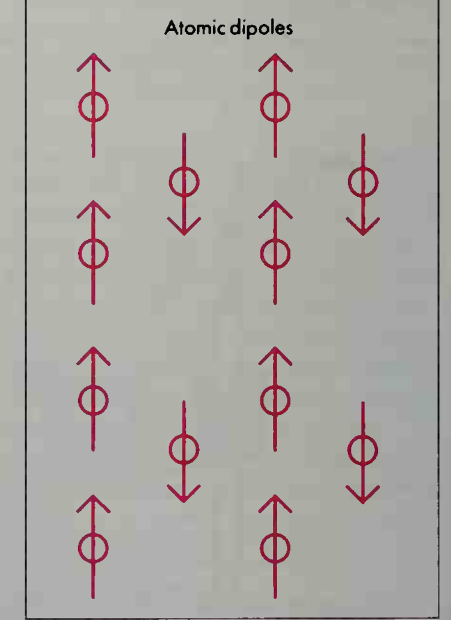
In addition to circling the nucleus, an electron spins on its axis like a top. This motion also produces an electric current and a magnetic field. But in most atoms, one electron spins in one direction for each electron that spins in the opposite direction. The magnetic fields caused by the spinning motion of the paired electrons cancel each other out.

The orbiting motions of paired electrons change slightly when an atom is placed in a magnetic field. The magnetic fields of the electrons then no longer cancel each other out, and their motions produce a weak magnetic field opposite to the external field. This effect is known as *diamagnetism* (opposite magnetism). The atoms making up most chemical compounds are held together by chemical links called *bonds* that consist of paired electrons. As a result, most compounds—including water, salt, and sugar—are diamagnetic. Diamagnetic materials are weakly repelled by magnets.



In some atoms, including those of cobalt, iron, nickel, oxygen, and the rare-earth element gadolinium, the spins of some electrons are not paired. As a result, each atom has a magnetic field and acts like a tiny magnet. Such an atom is called an *atomic dipole.* These atoms, like other magnets, tend to align themselves parallel to the lines of an external magnetic field. This alignment is called *paramagnetism* (same magnetism) and causes the individual atoms to be weakly attracted to magnets.

Magnetism of materials. In some paramagnetic materials, the atomic dipoles arrange themselves in certain patterns in relation to each other. These arrangements include *ferromagnetic, antiferromagnetic,* and *ferrimagnetic* ordering. In ferromagnetic materials, such as iron, an atomic dipole points in the same direction as neighboring dipoles. The ferromagnetic arrangement produces the most strongly magnetic substances. An atomic dipole in an antiferromagnetic material, how-



The magnetism of materials Certain materials have magnetic properties because of the arrangement of their *atomic dipoles,* atoms that act like tiny magnets because they have unpaired electron spins. These arrangements include ferromagnetic, antiferromagnetic, and ferrimagnetic ordering.

Ferromagnetic materials have atomic dipoles that align in the same direction as neighboring dipoles. Such materials are strongly magnetic.

Antiferromagnetic materials, which are weakly magnetic, have atomic dipoles that align opposite to neighboring dipoles.

WORLD BOOK illustrations by Linda Kinnaman

Ferrimagnetic materials have more atomic dipoles pointing in one direction than in the other and are strongly magnetic.

ever, points opposite to its neighbors. Antiferromagnetic materials are weakly magnetic. Ferrimagnetic ordering occurs in materials with several kinds of atoms, including magnetite and ferrite alloys. These materials have more dipoles pointing in one direction than in the other and are strongly magnetic.

Atomic dipoles of ferromagnetic and ferrimagnetic materials settle into an ordered arrangement when the material's temperature falls below its *magnetic ordering temperature* or *Curie point.* For antiferromagnetic materials, this temperature is called the *Néel temperature.* Iron, for example, has a magnetic ordering temperature of 1418 °F (770 °C); nickel, 676 °F (358 °C); and cobalt, 2050 °F (1121 °C). Above this temperature, stronger atomic vibrations prevent the atomic dipoles from arranging themselves in relation to each other. As a result, the materials then show only the weak magnetic attraction of paramagnetism.

In ferromagnetic and ferrimagnetic materials, the atomic dipoles usually align to form larger dipoles called *magnetic domains.* Domains combine the strength of the individual atomic dipoles. A piece of magnetic material may contain many magnetic domains. The domains often point in different directions, however, and tend to cancel each other out.

Ferromagnetic or ferrimagnetic materials become magnetized when exposed to a strong magnetic field. The domains parallel to the field grow as more atomic dipoles line up with it. If the magnetic field is extremely strong, all the atomic dipoles may align and the entire piece of material may become a single magnetic domain. The domains of a hard magnetic material remain aligned when removed from a magnetic field. Thus, the material becomes a permanent magnet. Soft magnetic materials, however, become *demagnetized* when removed from the field—that is, their original magnetic domains re-form and cancel each other out.

The magnetism of astronomical bodies

The magnetism of the earth. The earth is a giant magnet with poles called the *north magnetic pole* and the *south magnetic pole.* These poles are near the geographic North and South poles, respectively. The north magnetic pole attracts the north pole of a compass needle, so it is actually the south pole of the earth magnet. Similarly, the south magnetic pole is the north pole of the earth magnet because it repels the north pole of a compass needle.

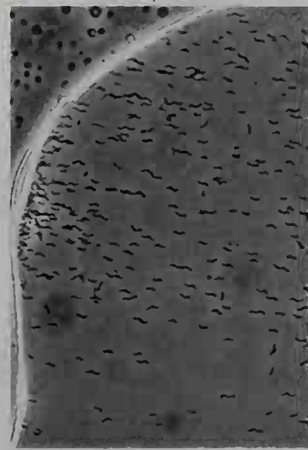
The magnetic field at the surface of the earth, known as the *geomagnetic field,* has a strength of about $\frac{1}{2}$ gauss. The earth's inner structure creates the geomagnetic field. The earth's *crust* is the outermost portion on which we live. A rocky *mantle* lies beneath the crust. Under the mantle is a dense *core,* which has a solid inner part and a liquid outer part. Scientists believe the motion of electric charges in the liquid outer core produces the geomagnetic field.

Scientists who study the lava of ancient volcanoes have found that the geomagnetic field periodically reverses direction—that is, the earth's north and south magnetic poles switch places. Lava contains small particles of hard magnetic material. When the lava was hot, these magnetic particles were paramagnetic and, thus, were only weakly influenced by the earth's magnetic field. But once the lava cooled below the magnetic ordering temperature, the particles aligned themselves with the geomagnetic field like tiny compass needles. Thus, lava leaves a record of the geomagnetic field at the time when the lava cooled.

The earth's magnetic field also extends into space beyond the atmosphere. There, it is called the *magnetosphere.* The magnetosphere interacts with a flow of charged particles from the sun called the *solar wind.* This interaction produces displays of light called *auroras* and a zone of charged particles around the earth known as the *Van Allen belts.*

The magnetism of the sun. The sun has an overall magnetic field of about 1 to 2 gauss. But it also has stronger magnetic fields concentrated in relatively cooler areas of its surface called *sunspots.* These regions have magnetic fields of 250 to 5,000 gauss. Other solar features associated with strong magnetic fields include bright bursts of light called *flares* and huge arches of gas known as *prominences.*

The magnetism of other astronomical bodies. The moon has virtually no magnetic field because it does not have a liquid core. But moon rocks brought to the earth by astronauts show that the moon at one time had a stronger magnetic field. This evidence suggests that it once probably had a liquid core. Mercury, Venus, and Mars all have weaker fields than the earth's. But Saturn, Jupiter, Neptune, and Uranus have relatively strong magnetic fields and magnetospheres.



Some types of stars have magnetic fields much stronger than the sun's. These stars include *white dwarfs,* which can have magnetic fields of more than 1 million gauss. A type of collapsed star called a *neutron star* can have a field as strong as 10 trillion gauss.

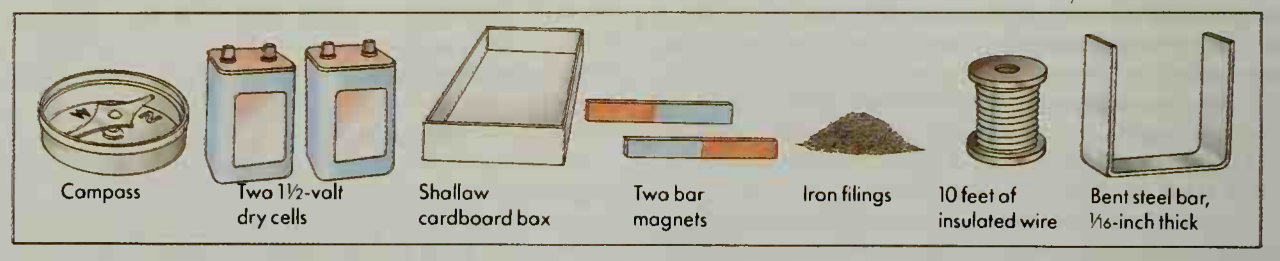
Magnets in living things

Scientists have discovered that many animals—including pigeons, honey bees, salmon, tuna, dolphins, and turtles—are able to detect the earth's magnetic field and may use it to help find their way. Scientists have found particles of magnetite in the body tissues of some of these animals. They suspect that the particles form part of a system that senses the geomagnetic field.

Scientists have also found that some bacteria in water use the geomagnetic field to find their preferred habitat. Each of the bacteria, called *magnetotactic bacteria,* contains one or more chains of magnetite particles. The

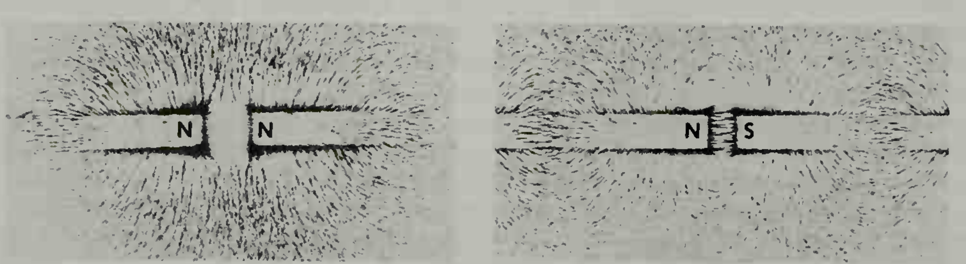
Richard Frankel, California Polytechnic State University

Magnetic bacteria contain extremely small chains of magnetite particles. The bacteria use the particles as tiny compasses to guide them along the earth's magnetic field lines. In this magnified picture of a waterdrop, almost all the bacteria are aligned left to right along a field line.



A *World Book* science project

Experimenting with magnetism

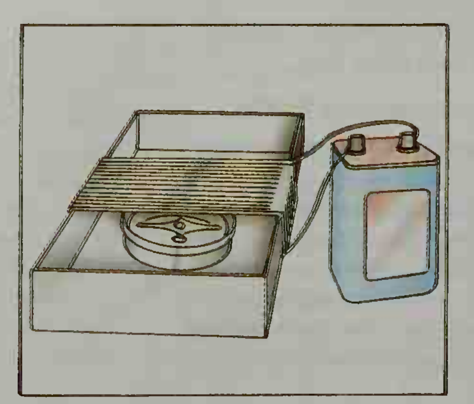


The purpose of this project is to demonstrate magnetic fields from permanent magnets and the magnetic effects of an electric current. The materials needed for this project are shown below. They can be purchased at most hardware or hobby stores.

Materials needed

WORLD BOOK illustrations by Oxford Illustrators Limited

Mapping magnetic fields

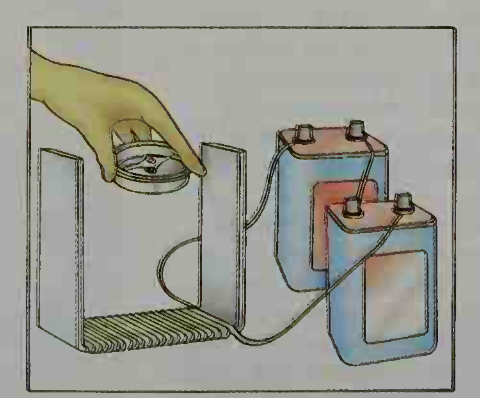


WORLD BOOK photos

To map the field of a bar magnet, place the magnet under a sheet of white paper. Sprinkle iron filings on the paper and tap the paper gently. The filings will line up as shown. The field between two magnetic poles curves outward from the gap between the poles if they are alike, *left.* If opposite poles are used, the field extends across the gap from one pole to the other, *right.*

Other experiments include mapping the field when one of the magnets is turned to a different position or when several magnets are placed under the paper. You can also study the effect of placing a steel coat hanger, coins, or other metal objects in contact with one or more magnets.

Magnetism and electricity



To see the magnetic effects of electricity, wrap about 10 turns of wire around a small box. Place a compass inside the box and turn the box so that the compass needle lines up with the wire. Strip the insulation from the ends of the wire, and connect the wire to the terminals of a dry cell. Then observe how the compass needle moves.

To experiment further, try switching the wires from one terminal to the other to see how the needle changes direction. By switching the wires at the proper rate, you may be able to make the needle spin completely around. Try changing the number of turns of wire to see the effect this has on the compass.

Experimenting with an electromagnet

To make an electromagnet, wind two layers of wire around a flat iron bar that is bent into the shape shown here. Strip the insulation from the ends of the wire and connect the wire to two dry cells. When you hold the compass between the poles of the electromagnet, the needle will pick up iron objects when the current is on.

Electromagnet experiments. Try mapping the field of your magnet. You can also change the number of turns of wire and the number of dry cells to increase the lifting power of the magnet. The more turns of wire you add or the more dry cells you connect, the stronger your magnet will be.

bacteria use the particles as tiny compass needles to guide them along geomagnetic field lines.

The study of magnetism

Early discoveries. People in ancient Greece and China independently discovered that natural lodestone magnets attracted iron. The Chinese also found that a piece of lodestone would point in a north-south direction if it was allowed to rotate freely. They used this characteristic of lodestone to tell fortunes and as a guide for building. By A.D. 1200, Chinese and European sailors used magnetic compasses to steer their ships.

In 1269, a French soldier named Pierre de Maricourt (also known as Petrus Peregrinus) mapped the magnetic field around a lodestone sphere with a compass. He discovered that the sphere had two magnetic poles. William Gilbert, a physician of Queen Elizabeth I of England, concluded in 1600 that the earth itself is a giant magnet with north and south poles.

Electricity and magnetism. In 1820, Hans Christian Oersted, a Danish physicist, observed that an electric current flowing in a wire caused the needle of a magnetic compass to rotate. His discovery proved that electricity and magnetism were related. The French physicist André Marie Ampère worked out the mathematical relationship between current and the strength of the magnetic field during the 1820's. He also proposed that electric current in atoms caused magnetism. In the early 1830's, the English scientist Michael Faraday and the American physicist Joseph Henry independently discovered that a changing magnetic field induced a current in a coil of wire. In 1864, James Clerk Maxwell, a Scottish scientist, developed the mathematical theory that described the laws of electricity and magnetism.

The magnetic properties of materials became a focus of research in the late 1800's. The French physicist Pierre Curie found that ferromagnetic materials lose their ferromagnetism above a certain temperature, which became known as the Curie point.

In the early 1900's, a number of physicists developed the theory of quantum mechanics, which describes the behavior of electrons and other particles. The pioneers of quantum theory included Niels Bohr of Denmark, Wolfgang Pauli of Austria, and the German physicists Albert Einstein, Werner Heisenberg, Max Planck, and Erwin Schrödinger. Richard P. Feynman and Julian S. Schwinger of the United States and Sin-itiro Tomonaga of Japan later developed an improved theory of quantum electrodynamics. Their work led to a better understanding of the interaction between charged particles and an electromagnetic field. John H. Van Vleck of the United States and Louis E. F. Néel of France applied quantum mechanics to understand the magnetic properties of atoms and molecules.

Modern research in magnetism. In the 1940's, the American physicists Edward M. Purcell and Felix Bloch independently developed a way to measure the magnetic field of nuclei. They placed a substance in a strong magnetic field and exposed it to radio waves. They discovered that the waves interacted with the nuclei of the substance's atoms. This discovery, known as *nuclear magnetic resonance,* led to magnetic resonance imaging and other methods for studying the structure of living tissues.

The American physicist Francis Bitter pioneered in developing stronger magnets for research. In the 1930's, he developed electromagnets made of water-cooled copper plates that generated powerful magnetic fields. In the 1960's and 1970's, scientists developed superconducting materials. When cooled to near *absolute zero* (−459.67 °F or −273.15 °C), these materials could be used in magnets to generate fields as high as 200,000 gauss. Superconducting magnets are used in maglev trains and in nuclear research. In the 1980's and 1990's, researchers discovered materials that become superconducting at higher, though still extremely cold, temperatures—about −280 °F (−173 °C). These new superconductors will enable scientists to generate even stronger fields.

Magneto, *mag NEE toh,* is an electric generator that provides spark ignition in some internal-combustion engines. Magneto ignitions are used in lawn mowers and in some aircraft and motorcycles. A magneto operates on two basic principles: (1) The movement of a conductor in a magnetic field produces an electric current in the conductor, and (2) A sudden interruption of the flow of the current in the conductor can *induce* (generate) large voltages.

A magneto consists of a magnet and a conductor made up of one or more coils of wire. The coils may rotate around the magnet, or the magnet may rotate inside the coils. The rotation induces an electric current in the coils. *Contacts* (connections) touching the coils are then opened, interrupting the flow of current and creating a high voltage in the coils. This voltage produces a spark that ignites fuel in the engine. Glenn A. Burdick

See also **Electric generator; Ignition.**

Magnetohydrodynamics, *mag NEE toh HY droh dy NAM ihks,* abbreviated MHD, is the study of the ways in which electric and magnetic fields interact with fluids that conduct electric current. These fluids include liquid metals and highly ionized gaslike substances called *plasmas.* MHD has helped to develop generators and propulsion systems that use conducting fluids. MHD also helps scientists understand electric and magnetic effects around the earth and on the sun. These effects include sunspots, magnetic storms in the earth's magnetic field, and *auroras* (northern and southern lights).

The principles of MHD have many applications. They are used in MHD generators, which produce electric power from a high-speed stream of plasma. The plasma shoots through a duct in a magnetic field, where it generates current that is drawn off by electrodes. MHD generators provide a highly efficient power source, but they are still experimental. MHD propulsion systems use electric power from a plasma or another conducting fluid to produce thrust. Such propulsion systems may someday power submarines and space vehicles.

The principles of MHD are also important in designing experimental *fusion reactors.* The fuel used in fusion reactors consists of plasma that has been heated many millions of degrees. But such extremely hot plasma would expand very quickly and would hit the walls of a container. The plasma would then be cooled and would lose energy too quickly for a fusion reaction to occur. Physicists are trying to produce controlled fusion in superhot plasma with confinement achieved by externally imposed magnetic fields. George Vahala

Magnetometer, *MAG nuh TAHM uh tuhr,* is a device that measures magnetic fields. A *magnetic field* is the influence that a magnet or an electric current creates in the region around it. Some magnetometers measure only the strength of a field. Others, called *vector magnetometers,* also measure the field's direction.

The simplest magnetometer consists of a coil of wire. This device operates by means of *electromagnetic induction:* If a magnetic field is present, turning the coil 180 degrees will cause an electric charge to flow through the coil. The amount of charge that flows will depend on the field strength.

The most sensitive magnetometers are called *superconducting quantum interference devices* (SQUID's). These use *superconductors,* materials that carry electric current without resistance at very low temperatures. A SQUID magnetometer can even detect weak magnetic fields produced by the human brain. Richard Wolfson

Magnifying glass is a lens which makes close objects appear larger. Both sides of the lens are usually curved to form a double convex lens. The magnifying glass can give two kinds of images. A glass held close to a page in a book forms a *virtual image.* The light rays which produce this image *diverge* (spread out) as they pass through the lens and appear to originate on the same side of the lens as the page. The virtual image appears upright and larger than the object.

A *real image* is formed when light rays from an object pass through the lens and are focused on the other side. The real image appears inverted, or upside down. Its size depends on the distance of the object from the lens. The distance from the center of the lens to the point where parallel light rays are focused is called the *focal length.* If the object is more than twice the focal length away from the lens, the image will be smaller. If the object is less than twice the focal length away, the image will be larger.

The magnifying power of a lens depends on its focal length. The greater the curve of a lens, the shorter its focal length and the greater its power. It bends the rays more, and they meet at a smaller distance from the lens. A lens with a focal length of 5 inches (13 centimeters) magnifies an image about two times.

A magnifying glass held between a piece of paper and the sun can be used to start a fire. Heat from the many rays focusing at a common point (focus) on the paper will make the paper burn. Joseph A. Muscari

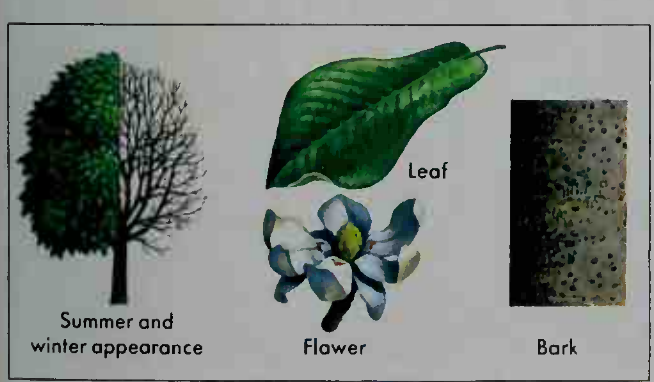
Magnitogorsk, *mag NEET uh gawrsk* (pop. 427,000), is the principal steel center of Russia. The city also makes mining machinery. Magnitogorsk is located in the Ural Mountains in southwestern Russia. For location, see **Russia** (political map). The city takes its name from its rich deposits of *magnetite,* a type of iron ore. Magnitogorsk was founded in 1931. Roman Szporluk

Magnitude is the scale used by astronomers to measure the brightness of objects in space. The brighter a star or planet, the lower its magnitude number. The magnitude system is based on the work of the ancient Greek astronomer Hipparchus. About 125 B.C., Hipparchus classified the stars according to brightness. He

called the brightest stars first magnitude; the next brightest, second magnitude; and so on down to the faintest stars visible with the unaided eye. He called such stars sixth magnitude.

Later astronomers found that first magnitude stars were about 100 times as bright as sixth magnitude stars. They adopted a system that made a star of any magnitude about $2\frac{1}{2}$ times as bright as a star of the next brightest magnitude. This scale has been extended to zero and negative magnitudes because some stars and planets are brighter than first magnitude ones. For example, the sun has a magnitude of −27.

The word *magnitude* generally refers to *apparent magnitude,* or the brightness of a star as seen from the earth. To compare actual brightness, astronomers use *absolute magnitude,* which shows how bright stars would appear if they all were the same distance—32.6 light-years—from the earth. At that distance, the sun would be a fifth magnitude star. Thomas J. Balonek



See also **Sirius; Star** (Brightness of stars).

Magnolia is the name of a group of trees and shrubs that grow in the Americas and in Asia. Eight of the 80 kinds grow wild in the Eastern United States. These eight and others are commonly cultivated. Magnolias have large flowers, conelike fruits, and large leaves.

The *southern magnolia* is popular because of its large whitish flowers. This evergreen is native from North Carolina to Florida and west to Texas. It is the state tree and flower of Mississippi and the state flower of Louisiana. *Sweetbay,* also called *swamp magnolia,* has smaller flowers and leaves. Its leaves are green on top and whitish underneath.

The leaves of the *umbrella tree* and the *big-leaf magnolia* tend to stretch out from the ends of the branches like the ribs of an open umbrella. The big-leaf magnolia has the largest flowers of any tree native to the United States. They measure about 10 inches (25 centimeters) across and are creamy-white. The big-leaf magnolia also has the biggest undivided leaves, which are 15 to 32 inches (38 to 81 centimeters) long and up to 10 inches (25 centimeters) wide.

The *saucer magnolia* is an ornamental tree that has been widely planted in the United States. It is a hybrid of two Asian magnolias and has many light to dark pink flowers. Magnolia lumber is used mainly for furniture. The *cucumber tree,* a magnolia that gets its name from the shape of its fruits, has wood similar to that of the yellow-poplar. Kenneth R. Robertson

WORLD BOOK illustration by John D. Dawson

The big-leaf magnolia has large flowers and leaves.

Scientific classification. Magnolias belong to the magnolia family, Magnoliaceae. The southern magnolia is *Magnolia grandiflora.* The sweetbay is *M. virginiana;* the umbrella tree is *M. tripetala;* the big-leaf is *M. macrophylla;* the saucer is *M. Soulangiana;* and the cucumber tree is *M. acuminata.*

See also **Yellow-poplar.**

Magpie is a bird that belongs to the same family as crows, ravens, and jays. The *black-billed magpie* lives throughout Europe, central Asia, parts of Siberia, and western North America from Alaska to New Mexico. The *yellow-billed magpie* lives in California.

Both yellow- and black-billed magpies are black with white underparts and wing tops. The black feathers of the wings and tail are tinged with a shiny bronze-green. The long tail of the bird narrows at the tip, and the bird's bill is heavy.

Magpies eat chiefly insects, including grasshoppers and beetles. The bulky nest of the magpie is usually in a bush or tree and is covered with a loose canopy of thorny sticks. The female lays five to seven bluish-green eggs spotted with brown and tan. The female incubates the eggs by sitting on them, and the male feeds her. Both the male and the female feed the young. Magpies live up to 12 years.

WORLD BOOK illustration by John Rignall, Linden Artists Ltd

The magpie is related to the crow. Magpies can mimic various bird calls and often steal food from the nests of other birds.

Magpies travel in pairs or small groups. However, these birds may gather in large numbers at roosts or sources of food. They have a large number of calls, such as their well-known rattling chatter and the soft, warbling sounds that are used between mates at the nest. Tame magpies may imitate the human voice or the calls of other birds. Edward H. Burtt, Jr.

Scientific classification. Magpies are in the crow family, Corvidae. The black-billed magpie is *Pica pica.* The yellow-billed is *P. nuttalli.*

Magritte, *ma GREET,* **René,** *ruh NAY* (1898-1967), was a Belgian surrealist painter. Magritte painted in a precise, realistic style that is often referred to as *magic realism.* His pictures present ordinary scenes but usually contain a combination of elements that normally do not belong together. This odd mixture gives his paintings an

eerie, dreamlike quality. Many of his paintings include mysterious men wearing bowler hats. The painting *Golconda* shows a pattern of these men suspended in air.

Magritte was born in Lessines, near Ath. He studied art in Brussels. His early paintings show the influence of cubism. Magritte's surrealist period began in 1922 after he saw a reproduction of a painting by the modern Italian artist Giorgio de Chirico. Rebecca Jeffrey Easby

See also Surrealism.

Maguey, *MAG way* or *mah GAY,* is the name given to several kinds of agave plants that grow in Mexico. The name is usually used for the *pulque agave.* Mexicans often drink the juice of this plant. They use it to make *pulque* (a fermented drink) and *tequila* (a distilled liquor). The plant's leaves are green with gray spines, and may grow 9 feet (3 meters) long and 1 foot (30 centimeters) wide. The greenish flowers grow on stalks 20 feet (6 meters) high. People often eat parts of the stems and flowers. See also **Century plant.** Michael G. Barbour

Scientific classification. The maguey is in the agave family, Agavaceae. The pulque agave is *Agave atrovirens.*

Magyars, *MAG yahrz,* are a group of people usually called Hungarians. They are traditionally considered descendants of the early Magyars, a people who founded Hungary in the late 800's. Today, Magyars make up almost all of Hungary's population. Millions also live in neighboring countries and in the United States and other Western nations. The Magyar language is in the Finno-Ugric group, which includes Estonian and Finnish.

From about 3000 B.C. to A.D. 500, the Magyars lived between the Volga River and the Ural Mountains in what is now Russia. By the late 800's, they had moved southwest to settle in what became Hungary. From then until the mid-900's, they raided many neighboring peoples. During the 1000's, the Magyars adopted Christianity and founded a powerful kingdom.

In 1526, the Ottoman Empire, based in what is now Turkey, defeated the Magyars. Hungary was divided between the Ottomans and the Austrian Habsburgs (or Hapsburgs). The Habsburgs expelled the Ottomans and gained complete control of Hungary in the early 1700's. Later, the Habsburgs were forced to share power with the Magyars in the kingdom of Austria-Hungary, which lasted from 1867 to 1918. Hungary became a separate republic in 1918. After World War I (1914-1918), many Magyars became inhabitants of neighboring countries when Hungary was reduced in size under the Treaty of Trianon. Steven Bela Vardy

See also **Hungary** (People; History).

Mah-jongg, *mah jawng,* also spelled *mah jongg* or *mah-jong,* is a Chinese game that developed in the 1800's. It is believed to be based on games played in China since about 500 B.C.

Mah-jongg is similar to the card game rummy. However, instead of cards, it is played with small, rectangular tiles engraved with Chinese drawings and symbols. There are 136 standard tiles, consisting of winds, dragons, and three kinds of suits—dots, craks, and bams. Suits are numbered from 1 to 9. There are four identical tiles of every kind. Most sets also have eight bonus tiles that represent flowers and seasons.

Two to six persons can play mah-jongg, but the game is best suited to four players. There are three main systems of rules—Chinese, Japanese, and American—and rules vary within each system. In general, players try to collect sets of three identical tiles (a *pong*), four identical tiles (a *kong*), or a sequence of three tiles within a suit (a *chow*). Players draw from a stack of tiles called the *wall,* discard tiles, and in some versions of the game, exchange tiles with other players. Players can also try to form special winning combinations that are worth different numbers of points. Usually, each player begins the game with chips equaling 1,000 points. Losers give chips to the winner equal to the value of the winning hand. R. Wayne Schmittberger

Mahabharata, *muh HAH BAH ruh tuh,* is an outstanding sacred writing of Hinduism and one of the two great epic poems of India. The other is the *Ramayana.*

According to Hindu tradition, the wise man Vyasa dictated the *Mahabharata* to Ganesh, the god of wisdom. Actually, the *Mahabharata* is a collection of writings by several authors who lived at various times. Parts of it may be more than 2,500 years old. The *Mahabharata* was written in Sanskrit, the principal literary language of ancient India.

The word *Mahabharata* means *Great King Bharata.* The epic poem tells the story of the descendants of King Bharata, two families who lived in northern India, per-

WORLD BOOK photo by Steven Spicer

A mah-jongg set has four of each of the wind, dragon, dot, crak, and bam tiles. Most sets include flower and season tiles.

haps about 1200 B.C. The Pandava brothers lose their kingdom to their Kaurava cousins and engage in a mighty struggle to win it back. The story illustrates the futility of war. Some of the heroes are taken from history, and some represent human ideals and gods.

The main story of the *Mahabharata* is often interrupted by other stories and discussions of religion and other subjects. The part called the *Bhagavad-Gita* is an important writing of Hinduism. Charles S. J. White

See also **Bhagavad-Gita; Ramayana; Hinduism.**

Mahan, *muh HAN,* **Alfred Thayer** (1840-1914), an American admiral, wrote many books on naval strategy and the influence of sea power on international affairs. His writings had an important effect on how nations viewed sea power in the 20 years before World War I (1914-1918). His great work, *The Influence of Sea Power upon History, 1660-1783* (1890), influenced President Theodore Roosevelt and others who supported colonial expansion overseas. Mahan argued in other writings for a strong navy, naval bases in Latin America and Asia, and an expanded merchant fleet. His ideas helped the United States develop as a world power and influenced naval experts in the United Kingdom and Germany.

Mahan was born at West Point, New York. He graduated from the U.S. Naval Academy in 1859. Mahan lectured at the Naval War College in 1886. These speeches later became *The Influence of Sea Power upon History.* His other books include the autobiography *From Sail to Steam* (1907). Mahan headed the War College from 1886 to 1889 and again in 1892 and 1893. He retired in 1896 as a rear admiral. Lewis L. Gould

Mahathir bin Mohamad (1925-) has been the prime minister of Malaysia since 1981. Under Mahathir, the economy of Malaysia grew rapidly until the mid-1990's, when an economic crisis struck Southeast Asia. Malaysia's economic growth then slowed, but Mahathir took steps to put the economy back on track. As prime minister, Mahathir has also worked to improve the economic condition of Malays. Malays make up the largest ethnic group in Malaysia, but Chinese Malaysians dominate the country's commerce and industry. Mahathir, a Malay himself, belongs to the country's largest political party, the United Malays National Organization.

Mahathir was born in Alor Setar. He graduated from the King Edward VII College of Medicine (now part of the National University of Singapore) in 1947. He became a government doctor and later went into private practice. Mahathir won his first seat in Malaysia's house of representatives in 1964. He later held a number of cabinet positions. He became prime minister in 1981 upon the resignation of Hussein bin Onn. Leonard Y. Andaya

Mahatma. See **Gandhi, Mohandas Karamchand.**

Mahfouz, *MAH fooz,* **Naguib,** *NAH geeb* (1911-), an Egyptian writer, became the first author writing in Arabic to win the Nobel Prize for literature. Mahfouz won the prize in 1988. Many of his novels deal with the various social classes of Cairo, Egypt. The many vivid characters in his fiction and the artistry he uses to put them into authentic Egyptian contexts place Mahfouz firmly in the tradition of the world novel.

Mahfouz's major work is the "Cairo Trilogy" (1956-1957). The three volumes are all named for streets in old Cairo. The English titles are *Palace Walk, Palace of Desire,* and *Sugar Street.* The novels tell the story of three generations of a Cairo family from World War I (1914-1918) to 1944, near the end of World War II. The trilogy provides a psychological portrait of Egyptian social change during the 1900's.

Many of Mahfouz's novels deal with controversial social and political topics, such as changing family roles and the role of religion in a modern, post-revolutionary society. His major novels include *Midaq Alley* (1947), *Children of Gebelawi* (1959), *Miramar* (1967), and *The Harafish* (1976). Besides writing about 40 novels, he has also written short stories, plays, and screenplays.

Mahfouz was born in Cairo. He graduated from King Fuad I (now Cairo) University in 1934 with a degree in philosophy. From 1934 to 1972, he worked in various arts-related government departments. Roger Allen

Mahican Indians, *muh HEE kuhn,* were important in the fur trade in North America during the 1600's. They struggled violently with the Mohawk Indians for control of the trade in the Hudson River Valley in New York. The Mahican Indians lived along the Hudson, and the name *Mahican* refers to the tides of the river near Albany. The Mahican are often confused with the Mohican, a fictional tribe created by American writer James Fenimore Cooper in his novel *The Last of the Mohicans.*

Mahican villages consisted of from 3 to 16 large rectangular dwellings called *long houses.* Each long house sheltered several related families. The Mahican grew much of their food in gardens near their villages. They also fished, hunted, and gathered wild plants.

The struggle between the Mahican and the Mohawk began about 1600. It lasted until the 1670's, when fur-bearing animals became so scarce in the valley that the fur trade no longer remained profitable. Increasing numbers of white farmers gradually forced the Mahican to leave their homelands. In 1736, many Mahican settled in Stockbridge, a community of Christian Indians in Massachusetts. These Indians moved to central New York in the 1780's. In the 1820's, the federal government set up the Stockbridge Reservation in Wisconsin. Most of the remaining Mahican still live there. T. Brasser

Mahler, Gustav (1860-1911), was a Bohemian-born composer of the Romantic period. He completed nine symphonies and died before finishing a 10th. He also wrote numerous songs, many with orchestral accompaniment. Much of Mahler's music has a religious or philosophical basis. The early works often describe nature, and the later ones the struggles and triumphs of the soul. Many of his works have a note of sadness and resignation. See **Classical music** (The romantic era).

Mahler's symphonies are large-scale works that try to include every human emotion. They employ a large orchestra, and four of them (Numbers 2, 3, 4, and 8) use voices. Although Mahler wrote for a large orchestra, he often used it very delicately. Mahler's songs are more intimate in style. They include *Kindertotenlieder (Songs on the Death of Children,* 1905) and *Das Lied von der Erde (The Song of the Earth,* 1911).

Mahler was born in Kaliště, Bohemia (now part of the Czech Republic). He studied at the Vienna Conservatory from 1875 to 1878. Mahler spent virtually his whole career as an opera and orchestra conductor. He directed the Vienna Court Opera from 1897 to 1907. After resigning this post, he visited the United States four times to conduct orchestras there. Joscelyn Godwin

Mahogany has long been considered one of the finest cabinet woods of the world, because it has most of the qualities desired for furniture making. It is strong and hard enough to stand ordinary use as furniture, yet soft enough to be easily sawed, planed, and carved. Mahogany does not shrink, swell, or warp as much as many other equally hard woods. The wood has an attractive color and grain, and a high luster.

Mahogany is a fairly heavy wood. Its color varies from light tan to dark reddish-brown. The wood darkens when exposed to daylight. It usually has an interlocking pattern or grain. Sometimes mahogany has curly, wavy, raindrop, or speckled figures. When mahogany is cut lengthwise through forks in the tree trunk, the wood shows a beautiful ostrich-plume effect. Workers often quartersaw or quarterslice mahogany into *veneer,* or thin sheets. They saw through the center of the log lengthwise so as to divide it into four sections. Then they cut planks alternately from each face of the quarter. Mahogany that has been quartersawed usually shows a ribbon or stripe figure.

The finest mahogany comes from the West Indies, where the tree *Swietenia mahagoni* grows to a height of more than 100 feet (30 meters). The long, clean tree trunk may reach a height of 60 to 80 feet (18 to 24 meters) before the first branch appears. Mahogany from this kind of tree is very scarce. Most mahogany used for fine woodworking today comes from southern Mexico, northern South America, and Africa. In Mexico and South America, the wood comes from the *Swietenia macrophylla* tree. In Africa, it is found in trees of the genus *Khaya. Philippine mahogany* comes from several trees in the genera *Shorea* and *Parashorea.* However, these trees are not true mahoganies.

The Cathedral of Santo Domingo in the Dominican Republic was the first building to use mahogany woodwork. The church was completed in 1540. In the 1700's, Chippendale, Hepplewhite, and other furniture makers made mahogany furniture popular. Jim L. Bowyer

Mahomet. See Muhammad.

Mahony, Roger Michael Cardinal (1936-), was appointed a cardinal of the Roman Catholic Church by Pope John Paul II in 1991. The pope had named Mahony archbishop of Los Angeles in 1985.

Mahony was born in Hollywood, California. He was ordained a priest in 1962. In 1964, he received a master's degree in social work from the Catholic University of America. Also in 1964, Mahony became the administrator of St. Genevieve's Parish in Fresno, California, and he was named pastor there in 1967. Mahony served as rector of St. John's Cathedral in Fresno from 1973 to 1980. He was chancellor of the diocese of Fresno from 1970 to 1977. Mahony served as auxiliary bishop and vicar general of that diocese from 1975 to 1980, when he was appointed bishop of the diocese of Stockton, California.
Robert P. Imbelli

Maidenhair tree. See Ginkgo.

Maidu Indians, *MY doo,* are a group of tribes in north-central California who speak related languages. A Maidu tribe traditionally consisted of about three to five villages. The tribal center was the village with the largest *kum,* a structure that served as both a house and a place for religious worship. In summer, the Maidu traveled through their territory to fish, hunt deer, and gather acorns and other foods. In winter, they returned to their villages and lived on the food gathered during summer. The Maidu relied heavily on their basket-weaving skills, which they used in making containers, fish traps, clothing, sleeping mats, and other items.

Between 1848 and 1910, the Maidu population dropped from about 9,000 to about 1,000. This dramatic decrease resulted from disease as well as from the Maidu being driven off their lands by gold miners and ranchers and being moved by the United States government to distant reservations. Today, about 1,000 Maidu live in their traditional homeland. Most of them live on reservations. Lee Davis

Mail. See Postal services.

Mail-order business is an industry involving the sale of products by mail. Mail-order companies, often called *mail-order houses,* have traditionally advertised by mailing leaflets, letters, or catalogs to customers. But today, many also advertise through magazines, newspapers, radio, television, telephone, and the Internet. Many firms also urge customers to place orders by telephone or on the Internet. Some firms invite customers to sales offices to select merchandise from catalogs or from samples on display. Because of the expanded scope of the traditional mail-order business, it is often referred to as the *direct-marketing business.* In the United States, sales in direct marketing total nearly $2 trillion annually.

The first mail-order firms in the United States were retail merchants who took orders by mail for certain types of goods. In 1872, Montgomery Ward and Company of Chicago became the first mail-order business to sell general merchandise. By the early 1900's, Sears, Roebuck and Co. of the United States had become the world's largest mail-order business. At first, the U.S. mail-order industry mainly served customers who lived on farms or in small towns. But after World War I (1914-1918), improved roads and the increased use of cars made it easier for rural people to shop in larger towns and cities. As a result, the mail-order industry began to decline. But the larger mail-order firms opened retail stores in urban areas.

After World War II ended in 1945, the mail-order business began to grow again. The industry recognized the importance of fast-growing city and suburban markets and developed new methods of reaching customers there. These methods included telephone-order services, catalog-sales offices in towns and suburbs, and increased circulation of catalogs in city areas. Today, companies use Internet Web sites to reach potential customers worldwide. The largest U.S. mail-order companies include the J. C. Penney Company and the Spiegel Group. Sears Canada dominates Canada's mail-order business. William H. Bolen

See also Eaton, Timothy; Sears, Roebuck and Co.; Ward, Aaron Montgomery.

Mailer, Norman (1923-), is an American author. His readers usually find his essays and novels fascinating and disturbing because they mirror the underside of modern culture. Mailer has analyzed the myths and unconscious impulses that underlie human behavior. He often stresses sex and violence, but he uses these elements for artistic purposes and not merely to shock.

Mailer first achieved success with his war novel *The*

Naked and the Dead (1948). In *Barbary Shore* (1951), he wrote about politics. *The Deer Park* (1955) describes the corruption of artistic and social values in Hollywood. *An American Dream* (1965) is a surrealistic journey through the power structures and obsessions of modern urban America. *Why Are We in Vietnam?* (1967) extends Mailer's thematic concerns through an examination of the violence he sees as basic to the American spirit. *The Executioner's Song* (1979) is based on the life of Gary Gilmore, a convicted murderer who was executed in 1977. The book won the 1980 Pulitzer Prize for fiction. *Tough Guys Don't Dance* (1984) is a violent detective story. *Harlot's Ghost* (1991) is a long, elaborate spy novel about the Central Intelligence Agency. *The Gospel According to the Son* (1997) is a fictionalized autobiography of Jesus Christ.

Many of Mailer's best essays about literature and culture were collected in *Advertisements for Myself* (1959) and *Existential Errands* (1972). *The Short Fiction of Norman Mailer* was published in 1967. *The Armies of the Night* (1968), which describes his experiences and observations during a peace demonstration, shared the 1969 Pulitzer Prize for general nonfiction. *Miami and the Siege of Chicago* (1968) represents Mailer's reactions to the 1968 national political conventions. He was born in Long Branch, New Jersey. Victor A. Kramer

Maillol, *ma YAWL,* **Aristide,** *a rees TEED* (1861-1944), was a French sculptor. He devoted more than 40 years of his career to the theme of the female form. Maillol's figures are his visions of beautiful, robust women, usually graceful and sensual. They are most often portrayed in quiet, deeply thoughtful poses.

The style of Maillol's female figures changed very little during his career. Maillol was inspired by the late sculpture of French artist Pierre Auguste Renoir. He also tried to reproduce the calm, harmonious spirit of classical Greek sculpture. Much of Maillol's work is life-sized and cast in bronze.

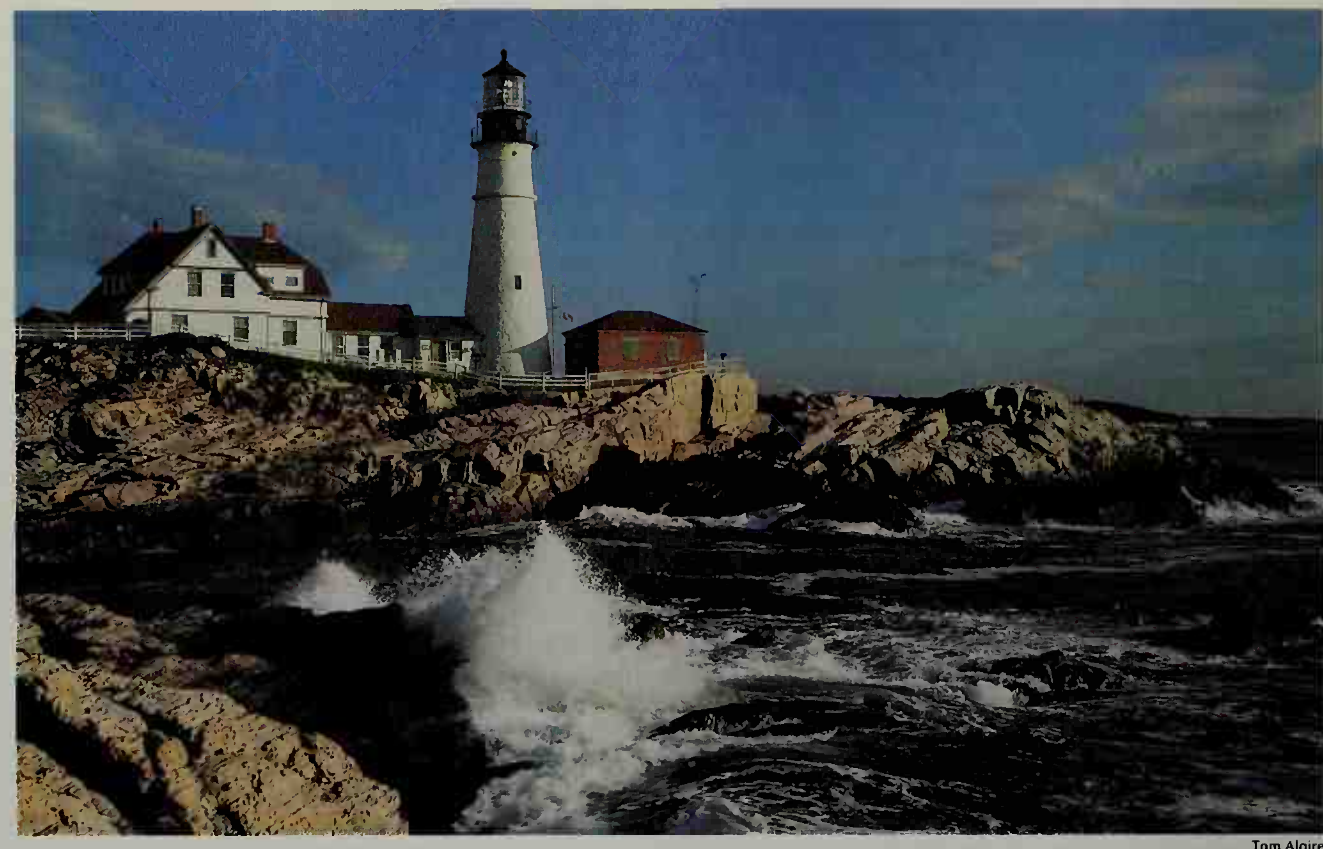
Maillol was born in Banyuls-sur-Mer, near Perpignan. He worked as a painter and a tapestry designer before turning full-time to sculpture about the age of 40. He also made woodcuts to illustrate books. Joseph F. Lamb

Maimonides, *my MAHN ih deez,* **Moses** (1135-1204), was the most important Jewish philosopher of the Middle Ages. Maimonides tried to demonstrate the compatibility of philosophy, as taught by the ancient Greek thinker Aristotle, with the Jewish tradition.

Maimonides' principal philosophical work, *The Guide for the Perplexed,* was written in Arabic and completed in 1190. It draws on Aristotle's works as transmitted by Greek and Muslim commentators. The *Guide* influenced Christian Aristotelian theologians, notably Saint Thomas Aquinas. In 1168, Maimonides completed a commentary to the *Mishnah,* the written version of traditional Jewish oral law. Maimonides completed the *Mishneh Torah* in about 1178. It became one of the most important Jewish law codes.

Maimonides was born in Córdoba, Spain. His Hebrew name was Solomon ben Maimon. Maimonides was a doctor by profession. However, he dedicated himself to the Jewish community in Cairo, Egypt, where he lived the last part of his life, and to furthering the study and practice of Judaism. Gary G. Porton

Maine. The sinking of the United States battleship *Maine* helped cause the Spanish-American War. The *Maine* arrived in Havana, Cuba, on Jan. 25, 1898, to protect American lives and property in case of riots. On Feb. 15, 1898, it blew up, killing about 260 of the crew. A naval court of inquiry concluded that a submarine mine had caused the explosion. The United States accused Spain in this matter because Havana was then a Spanish port. But Spain claimed that an explosion inside the ship caused the disaster. The slogan "Remember the *Maine*" aroused widespread patriotic sentiment in favor of war against Spain.



In 1976, U.S. Navy researchers led by Admiral Hyman G. Rickover studied the incident. They concluded that heat from a fire in a coal bin exploded a nearby supply of ammunition. H. Wayne Morgan

See also **Cuba** (picture); **Spanish-American War.**

National Archives, Washington

The sinking of the *Maine* in Havana Harbor on Feb. 15, 1898, angered the American people and helped spark the Spanish-American War. "Remember the *Maine*" became a popular patriotic slogan.

Tom Algire

The beautiful, rocky coast of Maine, with its thousands of bays and offshore islands, attracts vacationers to the state each year. The Portland Head Light, *above,* is one of the oldest and best-known American lighthouses. It was built in 1791.

Maine *The Pine Tree State*

Maine forms the northeastern corner of the United States. West Quoddy Head, a small peninsula of Maine, is the country's easternmost piece of land. Nearby Eastport lies farther east than any other U.S. city. On a map, northern Maine looks like a giant wedge between the Canadian provinces of New Brunswick and Quebec. Augusta is the capital of Maine, and Portland is the largest city.

Maine, the largest of the New England States in area, is probably best known for its beautiful shore on the Atlantic Ocean. Along this famous "rock-bound" coast of the state are lighthouses, sandy beaches, quiet fishing villages, thousands of offshore islands, and Acadia National Park—the only national park in New England. Jagged rocks and cliffs, and thousands of bays and inlets, add to the rugged beauty of Maine's coast. Inland, the state has sparkling lakes, rushing rivers, green forests, and towering mountains.

Many cities and towns lie in the lowlands of southern Maine. But forests cover nearly 90 per cent of the state. Trees from Maine's forests provide raw materials for a giant wood-processing industry, and this industry forms the backbone of Maine's economy. Mills in Maine make paper, pulp, toothpicks, and a variety of other products from trees. Maine leads the states in the production of toothpicks and ranks high in the manufacture of other wood products. Maine's nickname, the *Pine Tree State,* came from the tall pines that once made up much of the state's forests.

Service industries and fishing are also important in Maine. Thousands of people spend their summer vacations in Maine. They provide much income for lodging places, restaurants, and shops in the state. Maine leads all other states in lobster fishing.

Pioneering English colonists first settled in Maine in 1607, thirteen years before the Pilgrims landed at Plymouth Rock. Cold weather and lack of supplies forced the settlers back to England in 1608. English colonists made permanent settlements in Maine in the 1620's. Maine was a part of Massachusetts for the better part of 200 years. Then, on March 15, 1820, it became the 23rd state of the United States.

The name *Maine* probably means *mainland.* Early English explorers used the term *The Main* to distinguish the mainland from the offshore islands. New Englanders often refer to Maine as *Down East.* They call people who live in Maine *Down Easters* or *Down Easterners.* These terms probably come from the location of Maine east of, or downwind from, Boston. Ships from that port sailed down to Maine, and ships from Maine traveled up to Boston.

The contributors of this article are Richard H. Condon, Professor of History, and Paul B. Frederic, Professor of Geography, both at the University of Maine at Farmington.

Interesting facts about Maine

WORLD BOOK illustrations by Kevin Chadwick

The first earmuffs were patented by Chester Greenwood of Farmington on March 13, 1877. Greenwood invented his first pair in 1873, when he was 15 years old. He later mass-produced earmuffs in his Farmington factory. Farmington, once known as the *Earmuff Capital of the World,* observes a Chester Greenwood Day each winter.

Earmuffs

The most easterly point of land in the continental United States is West Quoddy Head, a small peninsula near Lubec.

The first person to win a Pulitzer Prize for poetry, Edwin Arlington Robinson, was born in Head Tide and grew up in Gardiner. Robinson won his first Pulitzer Prize in 1922 for *Collected Poems.* He later won two more Pulitzer Prizes—for *The Man Who Died Twice* in 1925 and for *Tristram* in 1928.

Camp Fire Girls originated in Sebago Lake in 1910. Luther Halsey Gulick, a national leader in recreational programs for young people, and his wife, Charlotte Vetter Gulick, founded the organization. In 1975, the organization began admitting boys. Today, it is known as Camp Fire Boys and Girls.

More wooden toothpicks are produced in Maine than in any other state. Manufacturers use white birch to make toothpicks.

Toothpicks

Dean Abramson, Stock Boston

Portland is the largest city in Maine and one of the chief ports on the Atlantic Coast. Portland is closer to Europe than any other U.S. transatlantic port.

A lobster fisherman removes a day's catch from his traps near Stonington. Maine has the largest lobster catch of any state.

Maine in brief

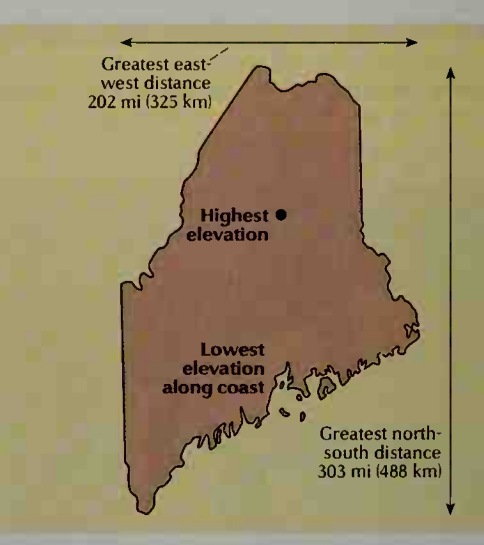
Symbols of Maine

The state flag, adopted in 1909, bears the state seal. On the seal, adopted in 1820, a farmer with a scythe represents agriculture. A seaman leaning on an anchor stands for commerce and fishing. These figures support a shield that displays a pine tree and a moose. The pine represents Maine's forests, and the moose symbolizes the state's undisturbed wildlife areas. At the top, the North Star represents Maine's northern location.

State flag

State seal

Maine (brown) ranks 39th in size among all the states and is the largest of the New England States (yellow).



The State Capitol is in Augusta, Maine's capital since 1832. Portland served as capital from 1820 to 1832.

General information

Statehood: March 15, 1820, the 23rd state.
State abbreviations: Me. (traditional); ME (postal).
State motto: *Dirigo* (I Direct or I Guide).
State song: "State of Maine Song." Words and music by Roger Vinton Snow.

Land and climate

Area: 33,128 mi² (85,801 km²), including 2,263 mi² (5,862 km²) of inland water but excluding 613 mi² (1,587 km²) of coastal water.
Elevation: *Highest*—Mount Katahdin, 5,267 ft (1,606 m) above sea level. *Lowest*—sea level along the coast.
Coastline: 228 mi (367 km).
Record high temperature: 105 °F (41 °C) at North Bridgton on July 10, 1911.
Record low temperature: −48 °F (−44 °C) at Van Buren on Jan. 19, 1925.
Average July temperature: 67 °F (19 °C).
Average January temperature: 15 °F (−9 °C).
Average yearly precipitation: 41 in (104 cm).

Important dates

- **1000?** Vikings probably visited the Maine coast.
- **1607** English settlers established the Popham Colony near the mouth of the Kennebec River.
- **1775** The first naval battle of the Revolutionary War took place off the Maine coast.
- **1820** Maine became the 23rd state on March 15.

For information about tourism, write to: Maine Office of Tourism, 59 State House Station, Augusta, ME 04333. The Web site at www.visitmaine.com also provides information.
For information on the economy, write to: Maine Department of Economic and Community Development, 59 State House Station, Augusta, ME 04333.
The state's official Web site at www.state.me.us also provides a gateway to much information on Maine's economy, government, and history.

1842 The Webster-Ashburton Treaty settled a long dispute over the Maine-Canada border.

1851 Maine was the first state to outlaw alcoholic beverage sales.

1969 Maine adopted personal and corporate income taxes.

1980 The U.S. government agreed to pay $81 $\frac{1}{2}$ million to Maine Indians for lands seized during the late 1700's and early 1800's.

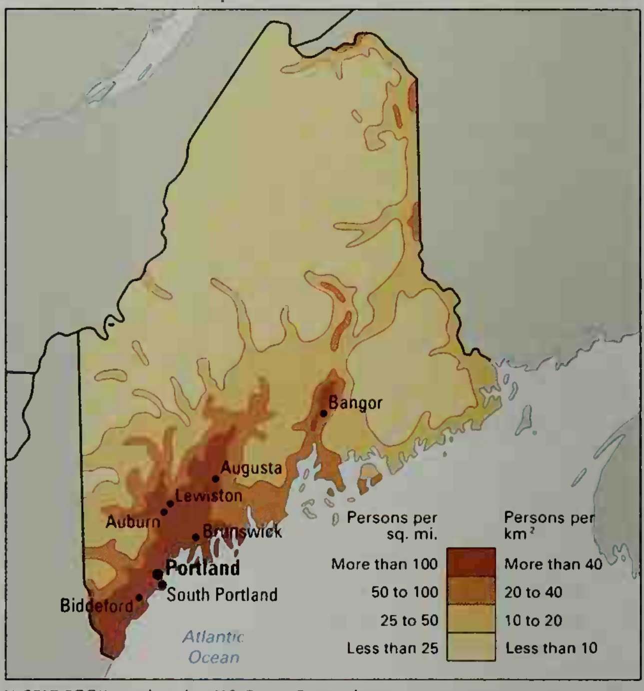
People

Population. The 2000 United States census reported that Maine had 1,274,923 people. The population had increased nearly 4 percent over the 1990 figure, 1,227,928. According to the 2000 census, Maine ranks 40th in population among the 50 states.

About 45 percent of Maine's people live in urban areas—that is, in or near municipalities with 2,500 or more people. The state's largest cities, in order of size, are Portland, Lewiston, Bangor, South Portland, Auburn, and Biddeford.

Three Metropolitan Statistical Areas are entirely within Maine (see **Metropolitan area**). They are Bangor, Lewiston-Auburn, and Portland. The Portsmouth-Rochester, New Hampshire, Metropolitan Statistical Area extends into Maine. More than a third of the state's people live in these four areas. For the populations of these metropolitan areas, see the *Index* to the political map of Maine.

About 96 of every 100 people in Maine were born in the United States. More than half of those born in other countries came from Canada. Maine's largest ancestry groups include people of English, French, Irish, French-Canadian, and German descent.



Schools. Colonial Maine offered little opportunity for formal education. Parents and local ministers often served as teachers. The first school in Maine may have been an Indian mission founded in 1696 by Sebastian Rasle, a Roman Catholic priest. Maine's first known school for white children opened in York in 1701. The first schoolhouse was constructed in Berwick in 1719. A school fund was provided by the state's Legislature in 1828. Schools in Maine began to receive tax support in 1868.

A commissioner of education and a nine-member State Board of Education head Maine's public-school system. The governor of Maine appoints the members, subject to the approval of the Legislature, to five-year terms. The governor appoints the commissioner of education, subject to the approval of the Legislature. Children ages 7 through 16 are required to attend school. For the number of students and teachers in Maine, see **Education** (table).

Libraries. One of Maine's earliest libraries was formed in 1751. This collection of books alternated between parish houses in Kittery and York. Maine now has

Population density

Most of Maine's people live near the coast in the southwestern part of the state. Only a few tiny towns lie in the thinly populated, mountainous region of northwestern Maine.

WORLD BOOK map, based on U.S. Census Bureau data.

Hanson Carroll, FPG

Fishing is a popular sport in Maine. The state's thousands of clear lakes, rivers, and streams offer a great opportunity for fishing enthusiasts. Hunting is also a popular form of recreation in Maine's vast woodlands.

approximately 275 public libraries.

The Maine State Library in Augusta and the Maine Historical Society Research Library in Portland own large collections of books about Maine and its history. The state's largest public libraries are the Bangor Public Library and the Portland Public Library.

Museums. The Maine State Museum in Augusta features exhibits on the state's history. The Peary-MacMillan Arctic Museum at Bowdoin College in Brunswick has displays on culture and environment in Arctic regions. The Portland Museum of Art owns large collections of paintings and sculptures. The Robert Abbe Museum of Stone Age Antiquities in Bar Harbor features Indian items.

Other museums in Maine include the Brick Store Museum in Kennebunk, the William A. Farnsworth Art Museum and Wyeth Center in Rockland, and the Maine Maritime Museum in Bath. See also the *Places to visit* section of this article.

A traditional bagpipe band marches down a street in Bar Harbor during the town's annual Fourth of July parade.

Visitor's guide

Maine's offering of historic sites, amazing scenery, family attractions, and arts and entertainment attracts thousands of vacationers yearly. Maine's coastal region is filled with galleries; boutiques; wide, sandy beaches; lively arts and entertainment communities; and magnificent period architecture. The state is famous for its beautiful peninsulas of rocky coast and quaint fishing villages.

Inland, visitors can marvel at the picturesque mountain views, wooded landscapes, historic villages, scenic covered bridges, and old family farms. Fishing enthusiasts can try their luck in one of Maine's many lakes, ponds, rivers, and streams. During the winter, visitors are lured to the state's many ski resorts and snowmobile and cross-country ski trails.

Each season features exciting events throughout the state. Many events are a celebration of Maine's heritage and culture. Among the state's outstanding annual events is the Maine Lobster Festival. This celebration is held in Rockland during the first weekend in August.

Windjammer Days at Boothbay Harbor

Places to visit

Black Mansion, in Ellsworth, is often called *Maine's Mount Vernon.* It resembles George Washington's Virginia home, Mount Vernon. Built about 1820, the Black Mansion has a low porch with a copper roof supported by decorative columns. Other features include fine china, silverware, furniture, and a winding staircase.

Burnham Tavern, in Machias, is the place where colonists met in 1775 to plot the capture of the British ship *Margaretta.* The *Margaretta* was captured during the first naval battle of the Revolutionary War. Burnham Tavern was built about 1770. The tavern still displays its original sign: "Drink for the thirsty, food for the hungry, lodging for the weary, and good keeping for horses."

First Parish Church is a Unitarian church in Portland. It was the site of Maine's only constitutional convention, which was held in 1819. Many of Portland's wealthiest families worshiped in the church during the 1700's and 1800's.

Fort Western, in Augusta, dates from 1754. It was at this fort that Benedict Arnold and his men met before marching up Maine to attack Quebec in 1775.

Old Gaol Museum, in York, is the oldest public building in Maine. It was built in 1653, and served as a *gaol* (jail) until 1860. Old Gaol Museum now houses local history relics.

Penobscot Marine Museum, in Searsport, displays valuable paintings, ship models, old sailing charts, navigation instruments, fishing and whaling equipment, ships' logs, books, and other historical items.

Portland Head Light, near Portland, towers 101 feet (31 meters) over the surf. Built in 1791, it ranks among the oldest and most famous American lighthouses.

Seashore Trolley Museum, near Kennebunkport, is the largest U.S. museum that exhibits only electric railroad equipment.

Shore Village Museum, in Rockland, contains the largest collection of lighthouse lenses and artifacts on display in the United States. Exhibits include buoys, life-saving gear, ship models, and *scrimshaw*—carvings or engravings made from whale teeth, whalebone, or sea shells.

Tate House is the oldest house in Portland. This three-story wooden structure was built in 1755. It includes quarters once used by slaves.

Wadsworth-Longfellow House, in Portland, ranks as Maine's most popular historic site. This building was the boyhood home of Henry Wadsworth Longfellow, the famous poet.

National parklands and forest. Maine's Acadia National Park is the only national park in New England (see **Acadia National Park**). Saint Croix Island International Historic Site, near Calais, marks the site of one of the first French settlements in North America. Part of White Mountain National Forest lies in southwestern Maine.

State parks and memorials. Maine has 30 state parks and 15 state memorials. It has no state forest system. For information on the parks and memorials, write to Director, Maine Bureau of Parks and Recreation, State House, Augusta, ME 04333.

Annual events

January-June

Winter activities in Bethel, Carrabassett Valley, Greenville, Jackman, Kingfield, Rangeley, and other places (January and February); Moosemainea in Greenville (mid-May-mid-June).

July-December

Clam Festival in Yarmouth (July); Belfast Bay Festival in Belfast (July); Windjammer Days at Boothbay Harbor (July); Blueberry Festival in Machias (August); Maine Festival of the Arts in Brunswick (August); Retired Skippers Race in Castine (August); Fairs in Bangor, Cumberland Center, Farmington, Fryeburg, Presque Isle, Skowhegan, Topsham, Union, Unity, and Windsor (various times during the summer and in early autumn).

Rockland Chamber of Commerce

Maine Lobster Festival in Rockland

Land regions. Maine has three natural land regions. They are, from southeast to northwest: (1) the Coastal Lowlands, (2) the Eastern New England Upland, and (3) the White Mountains Region.

The Coastal Lowlands cover southeastern Maine. They are part of a region of the same name that stretches along the entire New England coast. In Maine, the region extends from 10 to 40 miles (16 to 64 kilometers) inland from the Atlantic Ocean. Sandy beaches line the coast in the south. Old Orchard Beach, with 11 miles (18 kilometers) of hard-packed sand, is one of the longest and smoothest beaches on the Atlantic Coast. Salt marshes, crossed by tidal creeks, lie west of the beaches. In the northeast, the beaches shrink to small bays or strips of sand between high cliffs.

Most of the Coastal Lowlands lie near sea level. The land was once much higher than it is today. It was pushed down during the ice age, which ended about 11,500 years ago, by the weight of ice and snow. The tops of sunken hills form more than 400 offshore islands from about 2 to 25 square miles (5 to 65 square kilometers) in area, and thousands of smaller islands. Mount Desert, the state's largest island, covers about 100 square miles (260 square kilometers).

The Eastern New England Upland lies northwest of the Coastal Lowlands. The entire upland extends from the Canadian border to Connecticut. In Maine, the region is from 20 to 50 miles (32 to 80 kilometers) wide. The land rises from elevations near sea level in the east to about 2,000 feet (610 meters) in the west. The Aroostook Plateau lies in the northeasternmost part of the region. The plateau's deep, fertile soil is good for agriculture. Farmers there grow one of the country's largest potato crops. Many lakes dot the Eastern New England Upland south of the Aroostook Plateau. Swift streams also flow through this area. Most of them are fed by springs and by melted snow. Mountains cut through the center of the region.

The White Mountains Region covers northwestern Maine and part of New Hampshire and Vermont. In Maine, the region is about 5 miles (8 kilometers) wide in the north and 30 miles (48 kilometers) wide in the south. The White Mountains Region includes hundreds of lakes and most of Maine's highest mountains. The mountains are an extension of New Hampshire's White Mountains.

Coastline of Maine has many deep harbors and thousands of bays, coves, and inlets. If the state's coastline is

Mount Katahdin, the highest peak in Maine, rises 5,267 feet (1,606 meters) in the central part of the state. Maine's mountains attract many skiers and climbers.

© Henry A. Harding

Allagash Falls rushes along the Allagash River through a pine forest in northwestern Maine. The winding river flows for about 80 miles (130 kilometers) through the state's wilderness.

measured in a straight line, it totals 228 miles (367 kilometers). However, if all of the area that is washed by water is measured, the coastline totals 3,478 miles (5,597 kilometers).

Mountains. Mount Katahdin, Maine's highest peak, rises 5,267 feet (1,606 meters) in the central part of the state. Nine other mountains are more than 4,000 feet (1,200 meters) high, and 97 others are over 3,000 feet (910 meters) high. Most of the mountains are forested and look green all year long. Cadillac Mountain towers 1,530 feet (466 meters) on Mount Desert Island. It is the highest point on the Atlantic coast between Labrador, Canada, and Rio de Janeiro, Brazil.

Rivers and lakes. Maine has more than 5,000 rivers and streams. Two of the chief rivers, the Androscoggin and the Saco, begin in New Hampshire. They flow across southern Maine and empty into the Atlantic Ocean. Two other important rivers, the Kennebec and the Penobscot, rise in lakes of north-central Maine. They wind down the center of the state, and empty into coastal bays. The St. Croix River forms the southern part of the border between Maine and New Brunswick. In northern Maine, the St. John River also is part of the border with New Brunswick. The St. John is the longest river in the northern part of the state.

Many of Maine's more than 2,500 lakes and ponds gleam like blue gems among dark forests. Moosehead, the largest lake, covers about 120 square miles (311 square kilometers) in the west-central part of the state. Other large lakes in Maine include the Belgrades, the Grands, Rangeley, and Sebago.

Plant and animal life. Forests cover nearly 90 percent of Maine. Valuable trees include the balsam fir, basswood, beech, hemlock, maple, oak, pine, spruce, and white and yellow birch. The speckled alder, a common shrub, thrives in Maine's swamps and pastures. Witch hazel borders much of the state's forestland. Chokeberries, shadbush, sumac, and thorn apples grow along country roads and farm fences. Blueberry bushes carpet the ground in much of Hancock and Washington counties and in a few other areas.

Maine's most common wild flowers are the anemone, aster, bittersweet, black-eyed Susan, buttercup, goldenrod, harebell, hepatica, Indian pipe, orange and red hawkweed, white oxeye daisy, and wild bergamot. Lady's-slippers and delicate mayflowers are found scattered through many of Maine's wooded areas. Jack-in-the-pulpit, knotgrass, lavender, and wild lily of the valley grow along the coast and many lakeshores.

Bobcats and black bears are found in several areas of Maine, particularly in the northern and western woods and mountains. Other fur-bearing animals of the forests include beavers, foxes, lynxes, martens, minks, raccoons, and skunks. Game animals found in Maine include rabbits, squirrels, white-tailed deer, black bears, and moose.

More than 320 kinds of birds live in Maine. The most common ones are buntings, chickadees, grackles, owls,

sparrows, swallows, thrushes, and wrens. Ducks, gulls, loons, and other sea birds live on the coastal islands in the state.

The game fishes most commonly found in Maine's lakes and streams are brook trout, landlocked salmon, and smallmouth bass. Other fishes of the inland waters include bass, white and yellow perch, and pickerel. Every spring, thousands of alewives swim up Maine's coastal rivers to lay their eggs. Then they return to the ocean. Atlantic salmon are found in the Dennys, Machias, and other rivers. Fishes in the state's coastal waters include cod, flounder, hake, mackerel, pollock, striped bass, and tuna.

Climate. Maine has cooler weather than most of the rest of the United States. Arctic air and coastal winds from the *Labrador Current,* a cold ocean current that rises from the Arctic Ocean, keeps Maine from being warmed by Gulf Stream air. For this reason, Maine has few hot summer days.

Maine's temperature averages 15° F. (−9° C) in January and 67° F. (19° C) in July. The state's record low temperature, −48° F. (−44° C), was set in Van Buren on Jan. 19, 1925. Maine's record high temperature, 105° F. (41° C), was set in North Bridgton on July 10, 1911.

Maine's yearly *precipitation* (rain, melted snow, and other forms of moisture) averages about 41 inches (104 centimeters). The annual snowfall varies from about 70 inches (180 centimeters) near the coast to about 100 inches (250 centimeters) in the interior. The coastal area has much fog.

Stan Osolinski, FPG

A moose drinks in a Maine pond. Moose, bobcats, and black bears live in the remote regions of northwest Maine.

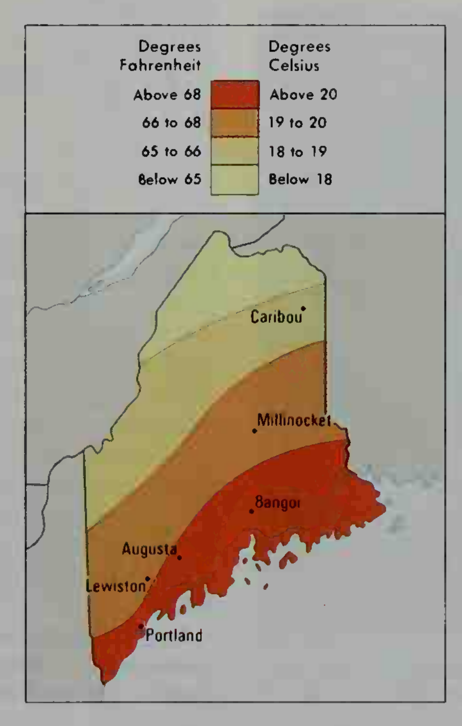
Average January temperatures

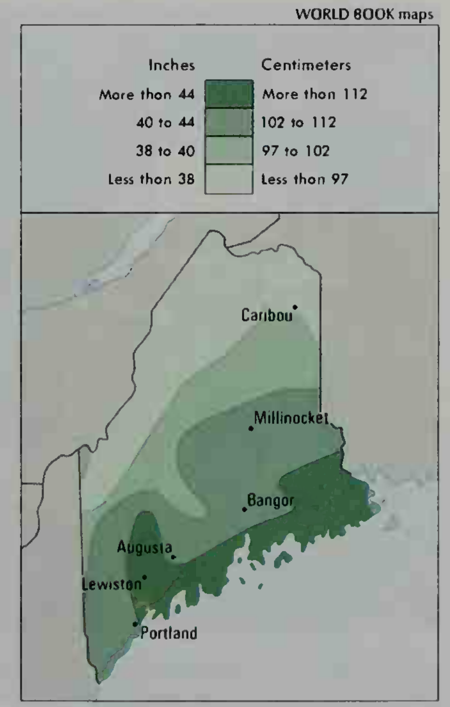


Maine winters are warmer than winters of many inland places as far north. Temperatures are coldest in the far north.

Degrees Fahrenheit / Degrees Celsius
Above 18 / Above -8
14 to 18 / -10 to -8
10 to 14 / -12 to -10
Below 10 / Below -12

Caribou
Millinocket
Bangor
Augusta
Lewiston
Portland

Average July temperatures



Maine summers are mild. Temperatures are warmest along the Atlantic coast and get increasingly cooler northward.

Average yearly precipitation

The greatest area of precipitation lies along the coast. The interior of the state receives the highest yearly snowfall.

WORLD BOOK maps

Economy

Maine's economy depends heavily on the state's natural resources. Extensive forests support the state's important paper and wood products industry. Fine coastal ports provide a base for Maine's valuable fishing and shipbuilding industries. Farming is important in southern Maine and in Aroostook County. The state's natural beauty also benefits the important service industries. Millions of tourists visit Maine each year, contributing significantly to the state's economy.

Natural resources of Maine include extensive forests, fertile soils, and some mineral deposits.

Forests cover nearly 90 percent of Maine's total land area—the highest percentage of any state in the nation. The forests supply the raw material for many products manufactured in Maine. Private companies and individuals own nearly all of Maine's forestland. Until the late 1700's, the white pine tree was Maine's greatest resource. The white pine was used mainly to make masts for ships. By the mid-1800's, the pines had been cut down throughout the state. Today, most of the state's many pine trees are second-growth trees. Other valuable trees that grow in Maine include balsam fir, basswood, beech, hemlock, maple, oak, spruce, and white and yellow birch.

Soil in Maine ranges from sand in the western part of the state to heavy loams in the northern regions. Clay soils cover much of Maine's lowlands. Gravelly soils are common at Maine's higher elevations. These soils once supported many small family farms. Today, farms are larger, but most are still family-owned.

Minerals. Southern Maine has many granite and limestone deposits, but few of them are mined. Tourmaline, a gemstone that is Maine's state mineral, is found in western Maine. Slate deposits lie near Brownville and Monson in the central part of the state. Aroostook County has one of the largest copper and zinc deposits in the United States. Other mined products include brick clay, feldspar, garnet, lead, peat, sand and gravel, silver, and stone. Most of the mines in Maine are on the coast and in the western part of the state.

Agriculture	2	27,100	3
Mining	†	300	†
Total	100	752,600	100

*GSP = gross state product, the total value of goods and services produced in a year.
†Less than one-half of 1 percent.
Figures are for 1998.
Sources: *World Book* estimates based on data from U.S. Bureau of Economic Analysis and U.S. Bureau of Labor Statistics.

Service industries, taken together, account for the largest portion of Maine's *gross state product*—the total value of all goods and services produced in a state in a year. Most of the state's service industries are concentrated in metropolitan areas.

Maine's leading service industry in terms of the gross state product is community, business, and personal services. This group also employs more people than any other economic activity in the state. Community, business, and personal services include private health care, hotels, law firms, and repair shops. Tourist activities contribute over $5 billion a year to the state's economy.

Ranking next among Maine's service industries are (1) wholesale and retail trade and (2) finance, insurance, and real estate. Each of these groups contributes an equal amount to the gross state product.

Portland, Bangor, and the Lewiston-Auburn metropolitan area are leading centers of Maine's wholesale and retail trade. Portland is one of the chief trading ports on the Atlantic coast. It plays a major role in the state's wholesale paper and pulp trade. Bangor is an important trade and distribution center on the Penobscot River. The Lewiston-Auburn area is a leading center of the textile trade. Important types of retail establishments in Maine include automobile dealerships, discount stores, grocery stores, and restaurants.

Portland is Maine's major center of banking and insurance. Real estate is a valuable part of this group because it includes the buying and selling of private homes.

Government is the fourth-ranking service industry. Government services include the operation of public schools and hospitals, and military establishments. Most government activities are based in Augusta.

Transportation, communication, and utilities ranks fifth among Maine's service industries. Shipping and trucking firms are the major part of the transportation industry. Telephone companies provide most of the income in the communications sector. Utilities provide electric, gas, and water service. More information about

these industries appears later in this section.

Manufacturing. Goods manufactured in Maine have a *value added by manufacture* of nearly $7 billion a year. This figure represents the increase in value of raw materials after they become finished products.

Paper products, which include cardboard boxes, paper bags, and pulp, as well as paper, are Maine's leading manufactured products in terms of value added by manufacture. Important paper and pulp mills operate in Bucksport, East Millinocket, Jay, Lincoln, Madison, Millinocket, Old Town, Rumford, Skowhegan, Winslow, Westbrook, and Woodland. Spruce and fir trees provide most of the wood used in Maine's paper and pulp industries.

Transportation equipment is Maine's second most valuable manufactured product in terms of value added by manufacture. The building and repair of ships and boats are important manufacturing activities in the state. Maine's shipbuilding industry employs about 9,000 workers. Factories near Portland also manufacture aerospace equipment.

Food products rank third among Maine's manufactured products. Canned and frozen foods are among the chief food products. Maine canneries produce soups and chowders, baked beans, and other products. Frozen fish and frozen potato products bring in much income. Maine food processing plants also pack lobsters, blueberries, and apples for shipping to other states. Bread, packaged chicken, and soft drinks are among the other processed foods produced in the state.

Computer and electronic equipment is the state's fourth-ranking manufactured product. The most valuable products made by this industry are microchips for personal computers. Communications equipment is another important product from this sector.

Tom Tracy, FPG

Huge rolls of paper are manufactured in a Maine paper mill. The production of paper and paper products, such as cardboard boxes, paper bags, and pulp, is Maine's leading industry.

Economy of Maine

This map shows the economic uses of land in Maine and where the state's leading farm, mineral, and forest products are produced. Major manufacturing centers are shown in red.

- Cropland mixed with grazing
- Woodland mixed with grazing
- Mostly forest land
- Manufacturing or service industry center
- Mineral deposit

WORLD BOOK map

Wood products rank fifth among manufactured goods made in Maine. Lumber is the leading type of wood product. Sawmills and lumber camps operate in many parts of the state. Specialty wood products are also important in Maine. The state leads the nation in toothpick production. Other specialty wood products include clothespins, lobster traps, and matches.

Other types of manufactured products made in Maine include fabricated metal products, leather products, and textiles. Plants in Cumberland and York counties make structural metal products. Footwear is the most important type of leather product. The L. L. Bean Company of Freeport is famous for its boots and other outdoor wear. Maine also is famous for its woven wool textiles.

Agriculture. Farmland covers about 5 percent of Maine's land area. The state has about 7,000 farms.

Livestock and livestock products account for about half of Maine's agricultural income. Eggs and milk are the leading livestock products. Egg production is greatest in the southern part of the state. Most of Maine's dairy farms are located in Androscoggin, Kennebec, Penobscot, Somerset, and Waldo counties. Beef cattle are Maine's third most valuable livestock product. Other livestock raised on Maine farms include chickens, hogs, sheep, and turkeys.

© Martin Rogers, FPG
Potatoes are Maine's most valuable farm crop. Maine is a leading potato-growing state.

Crops also account for about half of Maine's farm income. Potatoes are by far the most valuable farm crop. Maine is one of the leading potato-growing states. Most of Maine's 2-billion-pound (900-million-kilogram) annual potato crop comes from Aroostook and Penobscot counties. Oats are an important field crop in Maine. Many farmers rotate oats and potatoes to keep soil fertile. About two-thirds of Maine's farmland is used to raise crops to feed livestock. Many farmers grow corn, hay, oats, and other grains to feed cattle. Greenhouse and nursery products and broccoli, dry beans, peas, and other vegetables are also grown in Maine.

Apples are Maine's most valuable fruit crop. They are grown chiefly in Androscoggin, Kennebec, Oxford, and York counties. The chief variety is McIntosh. Other varieties include Cortland, Delicious, and Golden Delicious. Maine is also a leading producer of wild blueberries. Other Maine fruits include cranberries, raspberries, and strawberries.

Fishing industry. Maine's annual fish catch is valued at more than $250 million. Maine ranks high among the states in the value of fish and shellfish caught. Its yearly lobster catch is the largest of any state. Maine ranks second to Maryland in the quantity of soft-shell clams caught. The fish catch brings in valuable amounts of cod, flounder, ocean perch, pollock, and sea herring. Portland and Rockland are the chief fishing ports in Maine. Almost every community along the coast has at least a small fleet of fishing boats.

Mining. Maine's mining industry is based on the production of sand and gravel and limestone. Southwestern Maine produces most of the state's sand and gravel. Sand and gravel are used mainly to make roadbeds and concrete. Limestone is crushed for use in cement. Knox and Aroostook counties have limestone quarries. Crushed sandstone, traprock, and marl are produced in Cumberland and Penobscot counties.

Maine's other mined products include clays, garnet, gemstones, and peat. Garnet, used in grinding and polishing, is mined in Oxford County. Southwestern Maine also provides such gemstones as amethyst, topaz, and tourmaline. Brick manufacturers mine clays in Androscoggin and Cumberland counties. Washington County in eastern Maine has a large peat bog.

Northern Maine has large copper and zinc deposits. Mining companies have been slow to develop these deposits, however, because they are difficult to mine.

Electric power. Hydroelectric plants and petroleum-burning plants each account for about half of the electric power produced in Maine. The majority of the hydroelectric plants in Maine are located on the Androscoggin, Kennebec, Penobscot, and Saco rivers. The first United States power plant to produce electric power from peat began operation in Deblois in 1989. Maine also purchases much electric power from Canada to help fulfill its needs.

Transportation. Maine began developing good roads during the early 1800's. Today, the state has about 23,000 miles (37,000 kilometers) of roads and highways, almost all of which are surfaced. The Maine Turnpike runs about 100 miles (160 kilometers) between York and Augusta. Interstate Highway 95 extends the turnpike from Augusta to Houlton, near the Canadian border. United States Highway 1 follows the coast of Maine.

Maine's first railroad was built in 1836 to carry lumber between Bangor and Old Town. Today, three main railroads provide freight service within the state. These railroads are the Bangor & Aroostook, the St. Lawrence and Atlantic, and the Guilford Rail System. None of the freight railroads provide commuter service.

Portland International Jetport is Maine's busiest airport. Bangor International Airport is the closest airport to Europe within the United States.

Large oceangoing vessels can dock at some Maine ports. The state's busiest docks are located at Eastport, Portland, and Searsport. Eastport is closer to Europe than any other United States transatlantic port. It is a major entry point for oil that is shipped by pipeline to Canada. At the Port of Portland, the Bath Iron Works runs one of the largest dry-dock facilities for ship repair on the East Coast. Ferries operate between both Portland and Bar Harbor, Maine, and Yarmouth, Nova Scotia.

Communication. Maine has about 55 newspapers, 7 of which are dailies. The *Bangor Daily News* has the

Brian Smith, Stock, Boston
The Bath Iron Works in Bath is a leading U.S. shipbuilder. Many smaller Maine boatyards build fishing and sailing vessels.

largest circulation. Maine's other major newspapers include *The* (Brunswick) *Times Record,* the *Central Maine Morning Sentinel* in Waterville, the *Kennebec Journal* in Augusta, the Lewiston *Sun-Journal,* the *Portland Press Herald,* and the *Maine Sunday Telegram,* also in Portland. The *Falmouth Gazette,* Maine's first paper, began in Falmouth (now Portland) in 1785. About 50 periodicals also are published in the state.

Maine's first radio station, WABI, began operating in Bangor in 1924. The state's first television station, WABI-TV, started broadcasting in 1953 from Bangor. Maine has about 60 radio stations and 15 television stations. Cable television systems and Internet providers serve many communities.

Government

Constitution. Maine is governed under its original constitution. The Constitution was adopted in December 1819, about three months before Maine became a state. Amendments to the Constitution may be proposed by a two-thirds vote in both the Senate and the House of Representatives. To become effective, these amendments need the approval of a majority of the state's voters in a regular election. In addition, amendments can be proposed by a constitutional convention. A two-thirds vote in both houses of the Legislature is needed to call a constitutional convention. Maine has never held such a convention.

Executive. The governor is the only Maine executive official elected by the people. The governor serves a four-year term. The governor may serve any number of terms but not more than two in succession. Maine has no lieutenant governor. The Legislature elects the attorney general, secretary of state, and state treasurer to two-year terms. These officials are limited to serving four terms in a row. The Legislature also elects the state auditor to a four-year term. The auditor is limited to serving two terms in succession.

Legislature of Maine consists of a 35-member Senate and a 151-member House of Representatives. Each of the state's 35 senatorial districts elects one senator. Maine has 151 representative districts, each of which elects one representative. Senators and representatives are elected to two-year terms in even-numbered years. They are limited to serving four terms in a row.

Maine's Senate and House of Representatives hold two legislative sessions. The first session begins on the first Wednesday of December following the election. It may last until the third Wednesday in June. The second session begins on the Wednesday following the first Tuesday of January of the next even-numbered year. It may last until the third Wednesday in April. Either session may be extended for up to five days by a two-thirds vote of the Legislature.

Angus King	Independent	1995-

Courts. The Supreme Judicial Court is Maine's highest court of appeals for all civil and criminal cases. The court has a chief justice and six associate justices. Each justice serves a seven-year term. Maine's superior court handles all cases requiring trial by jury, and all cases appealed from lower courts. The 14 superior court justices serve seven-year terms.

Maine's 33 district courts, which are divided among the state's 13 districts, hear cases involving damages of less than $20,000. District court judges serve seven-year terms.

The justices of the Supreme Judicial Court, the superior courts, and the district courts are appointed by the governor with the approval of two-thirds of the Senate. Each county in Maine has a probate court, whose judges are elected by the people to four-year terms.

Local government. Each of Maine's 22 cities has *home rule.* That is, each city may adopt or revise a charter without approval of the Legislature. Most cities in the state have a mayor-council or city-manager form of government.

Maine has about 470 towns and *plantations* (small incorporated areas). Most towns consist of several communities governed together as a unit. The town meeting is the most common form of government in Maine towns. It allows citizens to take a direct part in government. Each year, voters assemble to elect officials, approve budgets, and do other business.

The chief town officials are called *selectmen.* Maine's plantations are each governed by a board of assessors. Maine also has hundreds of townships that have no organized government. These townships are grouped together into 36 territories. In addition, the state has three self-governing Indian townships, each headed by a governor, a lieutenant governor, and a tribal council. Each of Maine's 16 counties has its own government.

Revenue. Taxation provides about half of the state government's *general revenue* (income). Most of the rest comes from federal grants and other U.S. government programs. A personal income tax and a general sales tax each account for about one-third of the state tax revenue. Other important sources of tax revenue include taxes on motor fuels, corporate income, tobacco products, motor vehicle licenses, insurance, alcoholic beverages, and property. The property tax is a primary source of income for Maine's public school districts. Maine's other sources of general revenue include government services and a state lottery.

Politics. Maine was a Democratic state before the 1850's. But most Maine voters became Republicans in the period shortly before the American Civil War. They favored the Republican Party's antislavery and pro-Northern policies. For about a hundred years, until the 1950's, Maine voters almost always elected Republicans in state, congressional, and presidential elections. The Republicans are still a strong party in Maine. But since the 1960's, the Democrats have achieved a better balance of power with the Republicans. For example, the Democrats have often controlled the state Legislature.

Maine has voted for more Republican presidential candidates than any other state except Vermont. Since 1856, Democratic candidates have won Maine's electora votes only 6 times—in 1912, 1964, 1968, 1992, 1996, and 2000. For years, Maine held its elections for Congress and governor in September. Often, the party that did best in this election also did best nationally in the November elections. In the late 1800's, many people lookec to Maine's election results as an indicator of a national voting trend. This situation led to the slogan, "As Maine goes, so goes the nation." In 1960, Maine began voting in November. For Maine's voting record in presidential elections, see **Electoral College** (table).

Tom Jones Photography

Maine's House of Representatives meets in the State Capitol in Augusta. Representatives serve two-year terms.

Indian days. Thousands of Indians lived in what is now Maine before white settlers came. The Indians belonged to the Abenaki and Etchemin tribes of the Algonquian Indian family. The Abenaki lived west of the Penobscot River, and the Etchemin lived east of the river. The Indians had villages, but often moved in search of food. Their enemy, the Iroquois, frequently raided their villages. Maine Indians lived in peace with the earliest white settlers.

Exploration and settlements. Vikings, led by Leif Ericson, probably visited Maine about A.D. 1000. Many historians believe that John Cabot, an Italian sea captain in the service of England, reached Maine in 1498. France sent many explorers to Maine. These explorers and the dates they reached Maine included Giovanni da Verrazzano (1524), Pierre du Gua (or du Guast), Sieur de Monts (1604), and Samuel de Champlain (1604). Champlain explored and named Mount Desert, the largest island along Maine's coast.

In 1605, Sir Ferdinando Gorges and Sir John Popham, two wealthy Englishmen, sent George Waymouth to explore the Maine coast. Waymouth's favorable reports about the area led Gorges and Popham to attempt a settlement in Maine. In 1607, they financed a group of colonists who established Popham Plantation, near the mouth of the Kennebec River. The death of Popham that winter and Indian troubles forced settlers to return to England in 1608. While in Maine, the settlers built a boat called the *Virginia.* It was the first boat built by English colonists in America. The English made many permanent settlements in Maine during the early 1620's. Perhaps the first one was the settlement made near present-day Saco in 1623.

Ownership disputes developed over Maine during the 1600's. In 1622, the Council for New England, an agency of the English government, gave Ferdinando Gorges and John Mason a large tract of land in present-day Maine and New Hampshire. The land was divided between the two men in 1629, and Gorges received the Maine section. Gorges established Maine's first government in 1636. In 1641, he made the community of Gorgeana (now York) a city. It was the first chartered English city in what is now the United States.

After Gorges died in 1647, the people of Kittery, Wells, and York united under a new government. Between 1652 and 1658, they and the people of Casco Bay, Kennebunk, Saco, and Scarborough agreed to make Maine a part of the Massachusetts Bay Colony. In 1660, the heirs of Gorges disputed Massachusetts' ownership of Maine, and claimed Maine for themselves. In 1664, an English board of commissioners ordered Maine restored to the Gorges family. Massachusetts finally gained clear title to Maine in 1677, when it bought the area from the Gorges family.

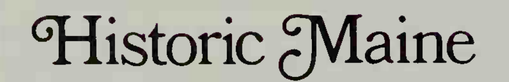
French and Indian wars were fought in Maine and the rest of New England off and on from 1689 to 1763. The French and their Indian allies battled to gain control of the area from the English colonists. William Pepperrell of Maine led the capture of the French fortress of Louisbourg, Nova Scotia, in 1745. The capture was one of the major events of the conflict. The French and Indian Wars ended with the Treaty of Paris in 1763. The treaty ended all French claims to Maine and most of the rest of North America.

The Revolutionary War. During the 1760's, Great Britain passed a series of laws that caused unrest in Maine and the rest of colonial America. Most of these laws either imposed severe taxes or restricted colonial trade. In 1774, a group of Maine patriots burned a supply of British tea stored at York. This event, called the *York Tea Party,* resembled the more famous Boston Tea Party of 1773.

The Revolutionary War (1775-1783) started at Lexington and Concord, Mass. Hundreds of Maine patriots joined the fight for independence. The war brought great hardships to Maine towns. In 1775, British troops burned Falmouth (now Portland) to punish the townspeople for opposing the king's policies.

The first naval battle of the Revolutionary War was fought off Machias in June 1775. In the battle, a group of Maine patriots captured the British ship *Margaretta.* Also in 1775, Benedict Arnold and his troops made a long march from Augusta to Quebec. They tried to capture Quebec from the British, but were pushed back. British troops occupied Castine in 1779. Colonial troops tried to recapture the town, but were badly defeated.

Maine's population increased greatly after the war. Massachusetts rewarded its soldiers with gifts of land in Maine, and sold Maine land to other persons.



In the early 1800's, Maine's economy depended on its pine forests. Wood from the forests was used to build ships and many other products. It was also traded for a variety of goods. The Embargo Act of 1807, which limited U.S. trade with other countries, hurt Maine's thriving shipping industry. But the slowdown in shipping forced Maine to seek new income by developing its manufacturing industries.

Statehood. In 1785, a movement began for the separation of Maine from Massachusetts and for Maine's admission to the Union. Many people in Maine protested heavy taxation, poor roads, the long distance to the capital city of Boston, and other conditions. But before the War of 1812, most voters wanted Maine to remain a part of Massachusetts. The separation movement grew much stronger after the war. Many of those who favored separation won election to the legislature. They swayed many voters to their side. The people voted for separation in 1819, and Maine entered the Union as the 23rd state on March 15, 1820. William King became the first state governor, and Portland was the first capital of Maine. Augusta became the capital in 1832.

Maine's admission to the Union became involved in the Missouri Compromise. The compromise called for Maine to enter the Union as a *free state* (a state without slaves) and Missouri to enter the Union as a slave state. This arrangement kept the number of slave and free states equal. See **Missouri Compromise.**

Ever since 1783, the boundary between Maine and New Brunswick had been disputed. The argument led to the so-called Aroostook War of 1839. The U.S. government sent General Winfield Scott to Maine, and he reached a temporary agreement with Canadian officials. No fighting took place. The boundary was finally set by the Webster-Ashburton Treaty of 1842. See **Webster-Ashburton Treaty.**

In 1846, Maine became the first state to pass a law prohibiting the manufacture and sale of alcoholic beverages. But the law did not provide for effective enforce-

Maine's northern boundary with Canada was fixed by treaty in 1842. Fort Kent was the center of an earlier dispute called the Aroostook War.

Maine entered the Union in 1820 as a free state (without slaves). Its admission was part of the Missouri Compromise.

The first naval battle of the Revolutionary War was fought off Machias in 1775, when patriots captured the British armed schooner *Margaretta.*

In 1775, Benedict Arnold led an army through the Kennebec Valley into Canada to attack Quebec.

Margaret Chase Smith, a Maine Republican, became the first woman to be elected to both houses of the United States Congress. She was born in Skowhegan.

Important dates in Maine

1000? Vikings probably visited the Maine coast.

1498 John Cabot probably explored the Maine coast.

1607 English settlers established the Popham Colony near the mouth of the Kennebec River.

1622 Maine lands were granted by royal charter to Sir Ferdinando Gorges and John Mason.

1641 Gorgeana (now York) became the first chartered English city in what is now the United States.

1677 Massachusetts bought Maine from the heirs of Ferdinando Gorges.

1763 The Treaty of Paris ended French efforts to gain control of Maine.

1775 The first naval battle of the Revolutionary War took place off the Maine coast.

1820 Maine became the 23rd state on March 15.

1842 The Webster-Ashburton Treaty settled a long dispute over the Maine-Canada border.

1851 Maine became the first state to outlaw the sale of alcoholic beverages.

1911 Maine adopted a direct-primary voting law.

1964 Maine voted for Lyndon B. Johnson, supporting a Democratic presidential candidate for the first time since 1912.

1969 Maine adopted personal and corporate income taxes.

1980 The U.S. government agreed to pay $81 $\frac{1}{2}$ million to the Passamaquoddy and Penobscot Indians of Maine for lands seized during the late 1700's and early 1800's.

Maine Maritime Museum

Ships built in Maine have been famous for more than 300 years. The *Roanoke, left,* was the largest wooden American full-rigged ship ever used in the merchant service. It was launched in 1892.

ment. In 1851, the state passed a new law that banned the production and sale of alcoholic beverages. This law remained in force until 1934.

Antislavery feelings grew strong in Maine during the early 1830's. The state's Baptists and Congregationalists opposed slavery especially strongly. About 72,000 Maine men served with the Union forces during the Civil War (1861-1865). Hannibal Hamlin, a former U.S. senator and governor of Maine, served as Vice President of the United States during the war under President Abraham Lincoln.

Industrial development increased greatly after the Civil War. The textile and leather industries were among those that grew at record rates. Farming activity and rural populations decreased as industry grew. During the 1890's, Maine began developing hydroelectric power on its rivers. Businesses competed for the best power sites, and the state legislature acted to protect the state's power interests. In 1909, the legislature outlawed the sale of hydroelectric power outside the state in order to keep the power in Maine and attract new industries. The law remained in force until 1955.

The early 1900's. In 1907, Maine adopted an initiative and referendum law (see **Initiative and referendum**). The state adopted a direct primary voting law in 1911. This law gives Maine voters a voice in choosing candidates for state elections.

The number of small farms in Maine continued to decrease during the 1920's. Many large farms were started, especially in Aroostook County. These farms specialized in potato growing and in dairy and poultry products. Industrial growth also continued during the 1920's. However, some Maine textile mills moved to the South because of lower costs there. The state made up its loss with a greatly expanded paper and pulp industry. The Great Depression of the 1930's slowed Maine's economy. But conditions improved as the depression eased in the late 1930's.

The mid-1900's. Margaret Chase Smith, a Maine Republican, won fame during the 1940's. She became the first woman elected to both houses of the U.S. Congress. Smith served in the House of Representatives from 1940 to 1949 and in the Senate from 1949 to 1973.

During World War II (1939-1945), Maine mills and factories produced military shoes and uniforms. Shipyards in Bath and South Portland built cargo and combat vessels. After the war, the state legislature passed laws to encourage industry to come to Maine. These laws included reduced tax rates for new businesses. The highway system was expanded, and many motels were built

AT&T Bell Laboratories

A satellite earth station near Andover sends and receives signals and tracks satellites as they orbit the earth. An inflated dome, *background,* covers an antenna. The control building, *foreground,* houses computing and tracking equipment.

The Maine Indian Claims Settlement Act was signed by President Jimmy Carter on Oct. 10, 1980. During the late 1970's, the Passamaquoddy, Penobscot, and Maliseet tribes of Maine sued to recover about 12 million acres (4.8 million hectares) of land taken by white settlers centuries ago. These tribes agreed to drop their lawsuit in exchange for an $81\frac{1}{2}$-million settlement from the federal government.

AP/Wide World

to accommodate Maine's growing tourist trade.

During the 1950's, Maine's economy was helped by the construction of Air Force bases. Small-scale farming all but ended in Maine, and some of the state's oldest textile mills closed. Many small electronics companies were established in the state during this period.

The state Department of Economic Development, established in 1955, and various community development groups helped bring new industries to Maine during the 1960's. Paper and pulp companies expanded, and Maine's food-processing industry also grew. Improved skiing facilities attracted thousands of winter tourists to the state.

The Democratic Party gained strength during the 1950's and 1960's. In 1955, Edmund S. Muskie became Maine's first Democratic governor since 1937. In 1958, he became the first Democrat ever elected to the United States Senate by Maine voters. President Lyndon B. Johnson won Maine's electoral votes in 1964—the first time Maine voted for a Democratic presidential candidate in more than 50 years. Muskie was the Democratic vice presidential candidate in 1968. Maine supported him and presidential candidate Hubert H. Humphrey. In 1969, the Maine legislature approved state personal and corporate income taxes for the first time.

Recent developments. In 1980, the United States government agreed to pay $81\frac{1}{2}$ million to the Passamaquoddy, Penobscot, and Maliseet Indians of Maine. The money was payment for Indian land seized through false and illegal treaties during the late 1700's and early 1800's.

Maine has benefited from efforts by environmentalists to clean up the state's rivers and harbors. Laws they sponsored have forced paper companies and municipalities to improve procedures to dispose of nuclear and other wastes. Maine's waterways are cleaner, and attempts to set up oil refineries at various coastal sites have been defeated. Still, issues such as acid rain and heavy cutting of forests continue to challenge the state (see **Acid rain**).

Maine's economic development was uneven in the 1970's, 1980's, and 1990's. The pulp and paper industry expanded rapidly at the start of the period, but increased automation later eliminated many jobs. Maine's valuable fir and spruce forests were overharvested and damaged by insects. A fishing boom led to overfishing. The resulting lower fish catch and foreign competition harmed Maine's fishing industry. Foreign competition also reduced employment in the state's shoe manufacturing industry.

Maine's economic problems occurred mainly in the northern and central parts of the state. Mainers in the southwestern area found jobs in shipbuilding and electronics and in new service industries. Coastal and ski areas profited from expanded tourism in the 1980's and 1990's. Richard H. Condon and Paul B. Frederic

Maine, University of, is a coeducational, state-supported system of higher education. The official name of the system is the University of Maine System.

The system has campuses in Augusta, Farmington, Fort Kent, Machias, Orono, Portland, and Presque Isle. The largest campus, at Orono, has colleges of business administration, sciences, education, forest resources, arts and humanities, social and behavioral sciences, engineering and technology, and applied sciences and agriculture. The Orono campus offers bachelor's, master's, and doctor's degrees. The Augusta campus grants mostly associate's degrees. The Farmington, Fort Kent, Machias, and Presque Isle campuses offer bachelor's degrees. The Portland campus, called the University of Southern Maine, grants bachelor's, master's, and professional degrees. It has a college of liberal arts, and schools of business and economics, education, law, and nursing.

The first campus was founded at Farmington in 1864. The University of Maine System was formed in 1968.

Maintenon, *man tuh NAWN,* **Marquise de,** *mar KEEZ duh* (1635-1719), was the second wife of King Louis XIV of France. She had great influence in France during his reign.

The future marquise was born Françoise d'Aubigné in Niort, France. In 1652, she married the much older Paul Scarron, who died in 1660. In 1669, she became governess to Louis XIV's children by his mistress, the Marquise de Montespan. But Louis grew to prefer the governess, giving her land and the title Marquise de Maintenon. After Louis's wife, Queen Marie-Thérèse, died in 1683, he secretly married Maintenon. Scholars disagree on the year of the marriage.

For more than 30 years, Maintenon was the king's trusted adviser. She was a deeply religious woman and tried to raise moral standards at court. Just before Louis's death, Maintenon helped him burn hundreds of documents that could have damaged his historical reputation. In 1686, she founded a school for girls at St. Cyr. Maintenon retired there after Louis died in 1715.

Mainz, *mynts* (pop. 179,486), is a commercial and industrial city in southwestern Germany. It lies where the Rhine and Main rivers meet. For location, see **Germany** (political map). Mainz serves as the capital of the state of Rhineland-Palatinate.

Mainz has a beautiful, old inner town. Its numerous landmarks include a cathedral that was begun in 975 and Johannes Gutenberg University, which was founded in 1477. The city's old buildings include examples of the Romanesque, Gothic, Renaissance, and Baroque styles of architecture. Mainz produces wines from grapes that are grown nearby. The city's other industries include the production of cement, machinery, motor vehicles, and printed materials.

Roman soldiers established a military camp on the site of what is now Mainz in 38 B.C. During the Middle Ages, Mainz became a prosperous city and the seat of archbishops. Saint Boniface became its first archbishop in A.D. 745. Peter H. Merkl

Mair, Charles (1838-1927), was a Canadian poet and journalist. His best-known poetry vividly describes the

beauty of the Canadian wilderness. Mair's poetry was collected in *Dreamland and Other Poems* (1868) and *Tecumseh: a Drama, and Canadian Poems* (1901). He also wrote *Through the Mackenzie Basin* (1908), a travel book describing the Mackenzie Basin in northwestern Canada. Mair's conservationist essay "The American Bison" (1890) led to the establishment of a sanctuary for one of the few remaining bison herds.

Mair was born in Lanark, Upper Canada (now in Ontario). During 1869 and 1870, he was a correspondent for the Toronto *Globe* and the Montreal *Gazette*. He helped found the "Canada First" movement, a group that promoted nationalist feeling after the formation of the Dominion of Canada in 1867. Rosemary Sullivan

Maitland, *MAYT luhnd,* **Frederic William** (1850-1906), an English historian, pioneered in the study of early English legal history. His scholarship produced much of what is known today about the history of Anglo-Saxon law. Maitland was able to sift through masses of contradictory and confusing evidence and find the truth. His important works include *History of the English Law* (1895), which he wrote with Frederick Pollack, and *Domesday Book and Beyond* (1897).

Maitland was born in London, and attended Eton school and Cambridge University. He studied law at Lincoln's Inn, one of the four famous "Inns of Court" in London, where lawyers lived and studied. He practiced law for several years, then became a professor of English law at Cambridge in 1888. Roland N. Stromberg

Maize. See **Corn.**

Majolica, *muh JAHL uh kuh* or *muh YAHL uh kuh,* is a type of pottery glazed with tin oxide to produce a soft white color. The name is sometimes spelled *maiolica.* Designs are painted on the white background with other metallic oxides. These oxides turn various colors on the background when the pottery is *fired* (baked).

Majolica is named for the Spanish island of Majorca, where pottery was exported to Italy. Spanish potters began exporting majolica to Italy in the mid-1400's. Centers for producing the pottery arose throughout Italy.

The word *majolica* should be used only to describe Italian tin oxide-glazed pottery. But the term is also used to refer to the elaborately molded pottery that has been chiefly made in England since the mid-1800's. However, unlike true majolica, most of this pottery is coated with a lead glaze and is generally larger and more decorative than true majolica. William C. Gates, Jr.

The Bargello, Florence, Italy (Art Resource)

Majolica, a type of Italian pottery, is glazed with tin oxide to produce a soft white color and decorated with bright designs. The majolica medicine jars above were made during the 1600's.

Major, John (1943-), was prime minister of the United Kingdom from 1990 to 1997. Major, a member of the Conservative Party, succeeded Margaret Thatcher and continued many of Thatcher's policies. For example, he worked to reduce government control over the economy, and he encouraged individual enterprise.

Major led the Conservatives to an election victory in 1992, but he later became increasingly unpopular both with the public and within his own party. The British economy had developed new strengths and weaknesses under Major's government. Telecommunications and other new areas prospered, but mining and shipbuilding faded. These changes left many workers with the wrong skills for the available jobs and aroused much discontent. Many voters also accused Major of failing to protect British interests as he sought closer ties with the European Union, an organization of European nations. Disagreements over the European Union caused divisions within Major's own party and weakened his government. In 1997 elections, the Labour Party defeated Major and his party by a landslide.

Major was born in Merton, a borough of Greater London. He left school when he was 16. In 1965, he took an entry-level job at a bank and worked his way up to executive positions. In 1979, Major was elected to Parliament. He served in a variety of Cabinet posts that involved economic policy, including minister for social security, chief treasury secretary, and chancellor of the exchequer. In 1990, the Conservatives chose Major to replace Thatcher as prime minister and party leader.

Paul E. Gallis

Majorca, *muh JAWR kuh,* also called Mallorca, *mah YAWR kuh* (pop. 534,511), is the largest island of the Balearic group. Majorca lies about 100 miles (160 kilometers) off the eastern coast of Spain, and it is a Spanish possession. For location, see **Spain** (political map).

Majorca has an area of about 1,400 square miles (3,626 square kilometers). Palma is the only large city. Many tourists visit Majorca. Farming and tourism are the island's chief economic activities. Products include almonds, figs, olives, oranges, and wine. Majorca has limestone and marble quarries and some manufacturing. Stanley G. Payne

See also **Balearic Islands; Majolica.**

Majority rule is a principle of democratic government that requires a decision to be approved by a majority of voters before it may take effect. A majority consists of at least one more than half the votes cast. Majority rule may be used to elect officials or decide a policy. It may be used by groups that range in size from a small private organization to a large nation. A majority differs from a *plurality.* A candidate with a plurality receives more votes than any other candidate, but not necessarily a majority. For example, in an election in which 10 people vote, a majority would require at least six votes. A plurality might be as few as two votes if one candidate got that number and no other candidate got more than one of the remaining eight votes.

In the United States, Congress and the state legislatures use majority rule to pass laws. A candidate for President also needs a majority of the 538 votes in the Electoral College to be elected. The plurality principle is followed in elections for Congress and for most state or local offices. Alexander J. Groth

Makalu, Mount. See Mount Makalu.

Makarios III, *muh KAR ee uhs* (1913-1977), a Greek Orthodox clergyman, became the first president of Cyprus in 1959. In July 1974, Cypriot troops led by Greek officers overthrew him, and he was forced to flee the country. He returned to Cyprus in December 1974 and served as president again until his death in 1977. While Makarios was out of office, Turkish troops took over a large part of northeastern Cyprus. See **Cyprus** (History).

Wide World

Makarios III

Makarios was elected bishop of Kitium in 1948. In 1950, he was elected archbishop and *ethnarch* (national leader) of the Greek Cypriots. He led the Greek Cypriot movement for independence from Britain and for *enosis* (union with Greece). Britain exiled Makarios to Seychelles in 1956 but freed him in 1957. He was elected president after Britain agreed to independence for Cyprus.

Archbishop Makarios was born in Pano Panayia, Cyprus. His real name was Michael Christodoulos Mouskos. He entered a monastery at age 13. He later studied at the National University of Athens in Greece. He also studied theology in the United States at Boston University. H. Ibrahim Salih

Malabo, *mah LAH boh* (pop. 15,253), is the capital of Equatorial Guinea. The city lies on Bioko, an island in the Gulf of Guinea (see **Equatorial Guinea** [map]). Malabo is an important seaport. It handles such exports as bananas, cabinet woods, cacao, cinchona bark, coffee, kola nuts, and palm oil. Most of the city's people work for import-export companies. An airport lies near Malabo.

British businessmen and colonists founded the city in 1827. The British called it Clarencetown or Port Clarence. Spain took control of the city in 1844 and named it Santa Isabel. Malabo received its present name in 1973 after Equatorial Guinea had gained independence from Spain. Immanuel Wallerstein

Malacca, *muh LAK uh,* **Strait of,** is a channel between the Malay Peninsula and the island of Sumatra. The strait connects the South China Sea and the Indian Ocean. It is about 500 miles (800 kilometers) long and from 25 to 100 miles (40 to 160 kilometers) wide. The city of Singapore lies on Singapore Island at the southeastern end of the strait. See **Indonesia** (map). The strait is an important shipping route. David A. Ross

Malachi, *MAL uh ky,* **Book of,** is a book in the Hebrew Bible or Old Testament. It was written by an anonymous prophet probably about 475 B.C. *Malachi* means *my messenger* and is probably not the writer's name, but a title taken from the book itself.

A central theme of the book is the corruption of the priesthood. This corruption, the book says, caused many people of Judah to question God's justice and to lose their faith. The prophet is also very concerned about intermarriage and predicts the coming of a "messenger" before God's final judgment. This messenger is identified with the prophet Elijah in the last verses. Later writers speculated that Elijah is to return from heaven to announce the Messiah and reunite Israel. This interpretation impressed both Jewish and Christian belief about the expected arrival of the Messiah. Eric M. Meyers

See also **Elijah; Bible** (Books of the Hebrew Bible).

Malachite, *MAL uh kyt,* is a beautiful green copper mineral. It consists of copper oxide, carbon dioxide, and water, and its chemical formula is $2CuO{\cdot}CO_2{\cdot}H_2O$. Malachite is formed in layers that vary in color from apple green to dark gray-green (see **Mineral** [picture]). It is used chiefly as an ornamental stone. Fine pieces of malachite have been mined in the Ural Mountains of Russia and in Arizona. Other sources of the mineral include Africa, Australia, and Mexico.

In ancient times, people made bracelets of malachite because they thought it provided protection against disease, lightning, and witchcraft. Some scholars believe malachite is the stone the Israelites called *soham.* This stone was one of the sacred jewels in the high priest's breastplate. Robert B. Cook

Malagasy Republic. See Madagascar.

Malamud, *MA luh mood,* **Bernard** (1914-1986), was an American author. Most of Malamud's fiction describes in a humorous but sympathetic way the misfortunes of city dwellers, particularly Jews.

Malamud's early stories, collected in *The Magic Barrel* (1958), are often comic and sometimes rely on supernatural elements for their humor. But many critics argue that he was at his best in realistic novels. These novels lead the reader to a deeper awareness of how even ordinary people can rise to noble stature, as in his first novel, *The Natural* (1952).

Malamud's novel *The Assistant* (1957) portrays the empty existence of Frank Alpine, a young man who robs a poor Jewish grocer. Alpine repents his crime and works for the grocer. In the process, he learns goodness and moral strength. After the grocer dies, Alpine converts to Judaism. Malamud won the 1967 Pulitzer Prize for fiction for *The Fixer* (1966). This novel examines how moral strength can be gained through oppression. The main character is a Russian Jew arrested for the murder of a Christian child. Although wrongly accused, he suffers quietly until a deepening sense of principle allows him to reach spiritual freedom.

Malamud's other novels are *A New Life* (1961), *The Tenants* (1971), *Dubin's Lives* (1979), and *God's Grace* (1982). His stories were collected in *The Stories of Bernard Malamud* (1983). Malamud was born in New York City. Victor A. Kramer

Malamute. See **Alaskan malamute.**

Malaria is a dangerous parasitic disease common in tropical and subtropical areas. It is caused by protozoans called *Plasmodia* and is transmitted by the bite of the female *Anopheles* mosquito. Victims of malaria suf-

fer attacks of chills and fever, and 1 million to 3 million people die of the disease yearly.

There are four types of malaria, each of which is caused by a different species of *Plasmodium.* The four protozoans that cause malaria are *P. falciparum, P. vivax, P. ovale,* and *P. malariae.* (The *P.* stands for *Plasmodium.*)

Symptoms. Malaria causes periodic chills, with fevers that may reach 106 °F (41.1 °C). *P. falciparum, P. vivax,* and *P. ovale* cause attacks of chills and fever that recur about every 48 hours. In *P. malariae* infections, chills and fever recur about every 72 hours.

A malarial attack lasts two or more hours and is accompanied by headache, muscular pain, and nausea. After each attack, the patient perspires, causing the body temperature to drop to normal. Between attacks, the patient feels better but is weak and anemic.

The most serious type of the disease is caused by *P. falciparum.* Its victims become weaker with each attack of fever, and most die if untreated. In *P. vivax, P. ovale,* and *P. malariae* cases, the attacks get less severe and finally stop, even without treatment. But in *P. vivax* and *P. ovale* infections, the symptoms may reappear after a long period of apparent freedom from the disease.

Spread. The life cycle of the *Plasmodium* protozoan includes three basic stages. The first stage occurs in the mosquito's body, and the second and third stages take place in a person's body. The first stage begins when the mosquito bites someone who has malaria. *Plasmodia* enter the insect's body and reproduce in its stomach. The protozoan young find their way into the mosquito's saliva.

The second stage occurs after the mosquito bites another person. *Plasmodia* from the mosquito's saliva enter the person's blood. They travel to the liver, where they multiply and form clumps of parasites. After several days, these clumps burst and release new *Plasmodia.*

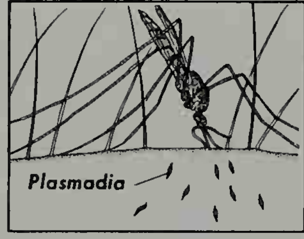
During the third stage, each *Plasmodium* invades a red blood cell, where it multiplies again. The infected blood cells eventually rupture and release large numbers of *Plasmodia,* which invade additional red blood cells. This invasion, multiplying, and cell rupture by the parasites continues, causing the periodic attacks of fever that are typical of malaria. An attack occurs each time the red blood cells rupture.

Some *Plasmodia* develop further in human blood and are able to reproduce in a mosquito's body. They enter the insect's body when the mosquito bites a person, and their life cycle begins again.

Treatment and prevention. Physicians diagnose malaria by identifying *Plasmodia* in a sample of the patient's blood. Most cases can be cured by using two drugs, chloroquine and primaquine. Some varieties of *P. falciparum* resist treatment by these drugs. In such cases, physicians prescribe quinine, mefloquine, or halofautrine.

Chloroquine can prevent malaria in addition to curing it. In most cases, people who plan to travel in areas where they could be exposed to malaria should take chloroquine before, during, and after their trip.

Prevention of malaria also involves controlling the *Anopheles* mosquito. To do so, workers spray people's homes with insecticides. They drain, spray, or fill in bodies of stagnant water where the insects breed. People also use mosquito netting and insect repellents and put screens on windows and doors.



During the 1950's and 1960's, the World Health Organization (WHO) tried to wipe out malaria. At first, the widespread use of insecticides, particularly DDT, eliminated malaria in some areas and greatly reduced the number of cases in others. However, the fight against malaria slackened, and the number of cases increased again. *Anopheles* mosquitoes became resistant to DDT and other insecticides, and some *Plasmodia* became resistant to drugs. Also, the cost of fighting malaria increased greatly. These problems prompted researchers to step up efforts to develop a vaccine that could help eliminate the disease. Wasim A. Siddiqui

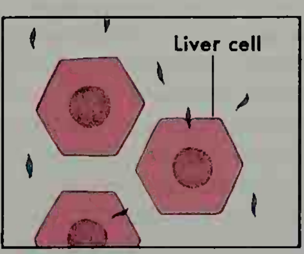
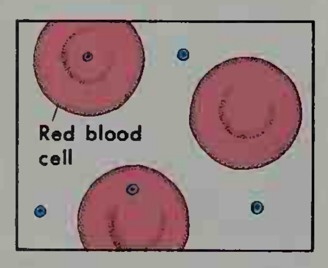
WORLD BOOK illustrations by Patricia J. Wynne

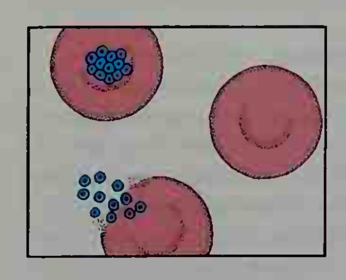
The life cycle of the malaria parasite



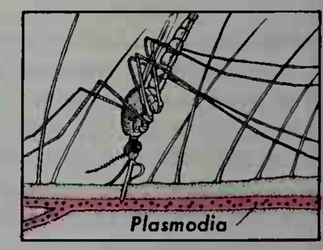
Malaria is caused by protozoans called *Plasmodia.* These organisms spend part of their lives in the bodies of human beings and part in the bodies of *Anopheles* mosquitoes. The disease spreads from person to person through the bite of these mosquitoes.



An infected mosquito injects *Plasmodia* with its bite.

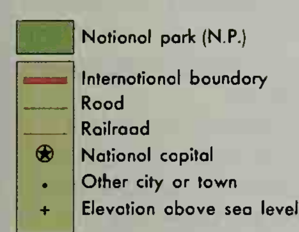


Each *Plasmodium* invades a liver cell and multiplies.



The cell bursts, releasing a new form of *Plasmodia.*

Each *Plasmodium* enters a red blood cell and multiplies.



The cell ruptures, and *Plasmodia* invade more red cells.

Some *Plasmodia* are able to infect mosquitoes.

Malawi

WORLD BOOK maps

Malawi, *mah LAH wee,* is a small scenic country in southeastern Africa. It is about 520 miles (837 kilometers) long and from 50 to 100 miles (80 to 160 kilometers) wide. Malawi lies on the western shore of Lake Nyasa, called Lake Malawi in that country.

Ancient volcanic activity left Malawi with rich soil. But only about one-third of the land is suitable for agriculture because mountains, forests, and rough pastures cover most of the country.

The country takes its name from the Malawi, or Maravi, kingdom, which was established by local people during the 1500's. Once the British protectorate of Nyasaland, Malawi became an independent country in 1964. Lilongwe is the capital of Malawi, and Blantyre is the commercial center and largest city.

Government. Malawi is a republic, with a president as its head of state and chief executive. The president appoints a vice president and a Cabinet to help govern the country. Under the Constitution, the people elect the president to a five-year term, but the president may not serve more than two consecutive terms. The people elect the 193 members of the National Assembly, which is Malawi's parliament, to five-year terms. The main political parties are the Alliance for Democracy, the Malawi Congress Party, and the United Democratic Front.

People. Most of Malawi's people are black Africans. The country also has some Europeans, Asians, and people of mixed origin. Most Malawians live in small villages. Houses in most villages are round and have mud walls and thatched roofs. The largest ethnic groups in Malawi are the Chewa (Cewa), Lomwe, Ngoni (Angoni), Nyanja, Sena, Tonga, Tumbuka, and Yao.

Most Malawians are farmers, and most of them raise only enough food for their families. Their main crop, corn, is pounded into flour to make a thick porridge called *nsima.* Many Malawians, primarily men, work on estates where tea or tobacco is grown. Traditionally, women have raised food crops and men raised crops for sale, but this situation is changing.

Some ethnic groups in Malawi determine family descent through the mother, and new households are established near their mother or relatives of the mother. However, other ethnic groups in Malawi trace descent through the father, as in most Western cultures.

English and Chichewa are Malawi's official languages. Chichewa is the most widely spoken language of central and southern Malawi, but ChiYao is also spoken in those areas. ChiTumbuka and ChiTonga are the main languages spoken in northern Malawi.

About 75 percent of Malawi's people are Christians, and about 20 percent are Muslims—that is, followers of Islam. Many of the people practice traditional religions. The country also has a number of Hindus.

Most of Malawi's school-age children attend primary school, and an increasing number now go on to secondary school. The University of Malawi is in Zomba. It has branch colleges or institutes in other cities.

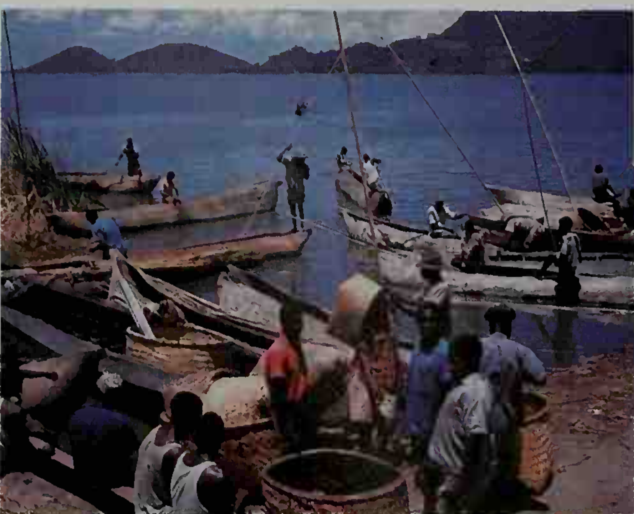
Land. Malawi is a land of great scenic beauty. Grassland and *savanna* (areas of coarse grass and trees) cover much of the land. The Great Rift Valley runs the length of Malawi from north to south. Lake Nyasa fills most of the valley. It is 1,550 feet (472 meters) above sea level. The Shire River flows out of the lake's southern end to the Zambezi River. West of the lake, the land rises steeply to a plateau about 4,000 feet (1,200 meters) above sea level. Malawi's highest mountain, Sapitwa (9,843 feet, or 3,000 meters), rises on a plateau southeast of the Shire River.

The lowlands in the Shire Valley and along the lake have a hot, humid, tropical climate. The temperature in this area averages from 74 to 78 °F (23 to 26 °C). The plateaus are much cooler. They average about 58 °F (14 °C) in higher areas and about 65 °F (18 °C) in lower areas.

Facts in brief

Capital: Lilongwe.
Official languages: Chichewa and English.
Area: 45,747 mi² (118,484 km²).
Population: *Estimated 2002 population*—11,449,000; density, 250 per mi² (97 per km²); distribution, 80 percent rural, 20 percent urban. *1987 census*—7,988,507.
Chief products: *Agriculture*—corn, cotton, hides and skins, peanuts, sorghum, sugar cane, tea, tobacco. *Manufacturing and processing*—bricks, cement, cotton goods, food processing.
Flag: The flag has black, red, and green horizontal stripes, with a red rising sun on the black stripe. See Flag (picture: Flags of Africa).
Money: *Basic unit*—kwacha. One hundred tambala equal one kwacha.

The northern parts of the country average about 70 inches (180 centimeters) of rainfall a year. The southwestern parts average only 30 inches (76 centimeters) a year.



Economy. Malawi is an extremely poor country. Its economy is based on agriculture, but only about a third of the land is suitable for farming. The most important export crop is tobacco. However, because of the decline of smoking in the United States and certain other countries, tobacco profits have been falling in Malawi. Another major export crop is tea, which is grown on European-owned estates in the highlands. Other important crops include sorghum, sugar cane, cotton, corn, and peanuts. A large number of farmers raise livestock.

Fishing on Lake Nyasa is an important industry and source of food. The country's few manufacturing industries produce bricks, cement, cotton goods, processed foods, and other products. Valuable hardwood forests cover northwestern Malawi, but high transportation costs for trucks to reach these remote areas have prevented the forestry industry from fully developing.

Malawi has over 7,000 miles (11,000 kilometers) of roads. However, only about 500 miles (800 kilometers) of the roads are paved. A main road runs the length of the country, and Malawi has roads linking it with Mozambique, Tanzania, and Zambia. A railroad in the Shire Valley connects Malawi with the Mozambique port of Beira on the Indian Ocean. Airports in Lilongwe and Blantyre provide air service to eastern and southern Africa.

History. Bantu-speaking people began living in what is now Malawi about 2,000 years ago. They formed kingdoms as well as smaller political groups. In the 1830's, two other Bantu groups, the Ngoni and Yao, invaded the area. The Yao were slave traders who sold slaves to the Arabs along the eastern coast of Africa.

The British missionary David Livingstone reached the area in 1859. He found it torn by local wars, and saw the suffering the slave traders caused. Livingstone called for "Christianity, commerce, and civilization" to bring peace to the area. In 1875, the Free Church of Scotland set up a mission that later became an important religious center. Scottish businessmen formed the African Lakes Corporation three years later to introduce lawful business instead of the slave trade. In 1889, the British made treaties with the local chiefs on the western shore of Lake Nyasa. Two years later, the United Kingdom proclaimed the territory as the Protectorate of Nyasaland.

Peter Schmid, Shostal

Malawi fishermen set out in canoes to catch fish in Lake Nyasa. Malawi is a beautiful but poor country, and fishing is an important industry as well as a source of food.

In 1953, the British made the protectorate part of a federation with Northern and Southern Rhodesia, the Federation of Rhodesia and Nyasaland. The Africans living there opposed the creation of the federation, and protested strongly against it. In 1958, Hastings Kamuzu Banda, a physician educated in the United States, became the leader of an independence movement in the protectorate. In July 1964, the protectorate gained independence as the nation of Malawi.

In 1966, Malawi adopted a one-party system of government. The Malawi Congress Party became the only political party, and Banda became president. A constitutional amendment was passed in 1970 to make Banda president for life. He assumed that title in 1971. In 1993, following widespread protests against Banda's government, the amendment was repealed, and Malawi's people voted for a multiparty system. In 1994, Bakili Muluzi, leader of the United Democratic Front Party, became president after he defeated Banda in a multiparty election. In 1995, Malawi adopted a new constitution. Muluzi was reelected president in 1999. John D. Metzler

Malaya, *muh LAY uh,* is a former name of Peninsular Malaysia—a region of the nation of Malaysia. For details on the region, see **Malaysia.**

Malays, *MAY layz* or *muh LAYZ,* are a group of Southeast Asian peoples. Most of the approximately 130 million Malays live in Indonesia and Malaysia.

The Malay culture is extremely diverse. It consists of about 300 ethnic groups that speak various dialects of the Malay language. Most of the groups are Muslims and work as civil servants or as rice farmers. Both men and women often dress in a traditional length of cloth worn as a skirt. In general, the Malays highly value social harmony, courtesy, and respect for authority.

Anthropologists believe the ancestors of the Malays migrated to Southeast Asia from southern China thousands of years ago. These ancestors practiced a religion based on *animism,* the belief that all things in nature—even lifeless objects—have spirits. Some Malays today combine animist beliefs with Islam or with other religions.

In the first century A.D., traders from India brought Hinduism and Buddhism to the Malay region. For hundreds of years, rival Hindu and Buddhist Malay kingdoms struggled against each other. In the 1400's, Muslim merchants and teachers from the Near East and India introduced Islam to the Malays. The ruler of Melaka, an important Malay kingdom, converted to Islam and promoted its spread.

In the 1500's, the Portuguese captured Melaka and became the first Europeans to influence the Malays. For most of the period from the 1700's to the mid-1900's, the Dutch ruled Indonesia and the British governed Malaysia. Indonesia and Malaysia then gained independence, and the Malays played a major role in shaping the two nations. James L. Peacock

Malaysia

Malaysia, *muh LAY zhuh* or *may LAY zhuh,* is a country in Southeast Asia that is divided into two parts. One part, known as Peninsular Malaysia, consists of 11 states on the Malay Peninsula and the federally administered cities of Kuala Lumpur and Putrajaya. The other part consists of two states called Sarawak and Sabah along the northern and northwestern coasts of the island of Borneo and the small island territory of Labuan off the coast of Sabah. The two parts of Malaysia lie about 400 miles (640 kilometers) apart, linked by the South China Sea.

Malaysia lies close to the equator and has a tropical climate that is hot and humid. Thick rain forests cover parts of both Peninsular Malaysia and Borneo.

Malaysia is rich in natural resources. It has long ranked as a leading producer of rubber and tin, as well as timber, a vegetable oil called palm oil, natural gas, and petroleum. In the late 1900's, Malaysia also became a major manufacturing nation and a successful exporter of electronic products.

Malays, Chinese, and Indians form the largest ethnic groups in Malaysia. More than 80 percent of the people live in Peninsular Malaysia. Most of the nation's urban areas are also there, including Kuala Lumpur *(KWAH luh loom POOR),* Malaysia's largest city.

Europeans arrived in what is now Malaysia in the 1500's. In 1511, the Portuguese seized the commercial kingdom of Melaka from the Malays but failed to conquer other areas on the Malay Peninsula. The Dutch defeated the Portuguese in 1641 and took over Melaka. In the late 1700's, the British arrived. They signed a treaty with the Dutch in 1824 that gave them control over the Malay Peninsula. But total British control was not established until the early 1900's. Peninsular Malaysia became an independent nation called Malaya in 1957. Malaya, Sarawak, Sabah, and the island of Singapore united to form the Federation of Malaysia in 1963, but Singapore withdrew two years later and became independent.

Government

Malaysia is a constitutional monarchy and a parliamentary democracy. The country is divided into 13 states and the Federal Territory of Malaysia. The Federal Territory consists of three areas, each administered by the federal government. These areas are Kuala Lumpur, the national capital; Putrajaya, the national administrative center; and the island of Labuan. Hereditary rulers, most of whom are called sultans, rule 9 of Malaysia's 13 states. From among themselves, the nine rulers choose a king called the *yang di-pertuan agong,* meaning *paramount ruler.* The king is the head of state. He serves a five-year term, performing mainly ceremonial duties, before the kingship rotates to another of the nine hereditary rulers.

National government. A prime minister and a parliament run the federal government. Parliament has two houses, a house of representatives called the Dewan Rakyat and a senate called the Dewan Negara. The Dewan Rakyat has 193 members, consisting of 144 from Peninsular Malaysia, 28 from Sarawak, 20 from Sabah, and 1 from Labuan. The people elect these representatives for five-year terms, unless an election is called earlier. Normally, the leader of the political party with the most seats becomes prime minister. The prime minister then chooses a cabinet. The Dewan Negara has 70 members, all of whom serve three-year terms. The 13 state legislatures elect 2 members apiece. The king appoints the other 44 members with the advice of the prime minister. Two of the appointed members represent Kuala Lumpur, 2 represent Labuan, and the other 40 are appointed on the basis of distinguished public service or to represent ethnic minorities.

Local government. Nine of Malaysia's 13 states were formerly kingdoms and continue to be governed by their traditional rulers. The other four states have gover-

nors appointed by the federal government. Each of the 13 states has its own constitution, legislature, and local officials.

Political parties. The most powerful political organization in Malaysia is an alliance called the National Front. The largest party in the alliance is the United Malays National Organization (UMNO). The two major opposition parties are the Democratic Action Party, the members of which are mainly Chinese, and the Islamic Party of Malaysia, which represents Muslim interests.

Courts. The Federal Court, formerly called the Supreme Court, is the highest judicial body in Malaysia. It has 10 members, who are appointed by the king on the prime minister's advice. Below it is a Court of Appeal, and at the next level are two high courts, one for Peninsular Malaysia, the other for Sabah and Sarawak. Lower courts include local and juvenile courts. Special religious courts issue rulings on Islamic law, called *Sharī'a,* also spelled *Sharī'ah.* Jury trials were abolished in 1995.

Armed forces of Malaysia has three branches: the Malaysian Army, the Royal Malaysian Navy, and the Royal Malaysian Air Force. Malaysia's armed forces have about 111,500 active members. All service is voluntary.

People

Malaysia's population is racially and ethnically diverse. Three groups of people have lived on the Malay Peninsula since prehistoric times: (1) a forest-dwelling people called the Orang Asli, who were mainly hunters and gatherers; (2) a coastal people called the Orang Laut,

who earned a living by fishing and seafaring; and (3) the Malays, who primarily farmed and fished. Today, the Malays make up more than half the country's population.

Two other large ethnic groups came to what is now Malaysia during colonial times, in the 1800's and early 1900's. These two groups were the Chinese, who came to work in tin mining or retail trade, and Indians, who came to work on rubber plantations. When Sabah and Sarawak became part of Malaysia in 1963, the peoples of Borneo added still other ethnic groups to this multiracial land. Sabah's largest ethnic group is the Kadazans. In Sarawak, the largest group is the Ibans, also called the Sea Dayaks. Still another wave of immigration began in the 1970's because of an economic boom. Hundreds of thousands of migrant workers, mainly from Indonesia, poured into Malaysia to fill manufacturing jobs.

The Malays dominate Malaysia's government and armed forces, but the Chinese control much of the economy. Many Chinese Malaysians resent the political power of the Malays. The Malays, in turn, resent the other group's wealth. The tensions between the Chinese and the Malays have erupted in violence from time to time.

Malaysians use several different languages. The Malay language is called Bahasa Malaysia, which means *language of Malaysia.* It is the country's official language. Many Malaysians also speak English. Many Malaysians of Chinese descent speak southern Chinese dialects, though a large number also know some Mandarin Chinese. Many Indian Malaysians use a southern Indian language called Tamil. Many smaller ethnic groups, such as the Kadazans, speak their own language but can also communicate in Bahasa Malaysia.

Way of life

Rural life. Most people in the rural areas of Peninsular Malaysia are Malays who farm or fish. Rural Malays live in villages called *kampongs,* also spelled *kampungs.* Their houses are built on stilts with wooden or bamboo walls and floors, and thatched palm roofs. Such raised construction prevents flooding in the rainy season and allows air to circulate more freely to cool the interior. Well-to-do families may have tin or tile roofs.

Most rural families grow rice as their staple food. They supplement the rice by raising fresh vegetables and by fishing in flooded rice fields or nearby streams. Most farm families also raise a few rubber trees and sell the rubber to add to the family income. The Malays along the coast earn their living primarily by fishing.

In Sabah and in Sarawak, many people live in isolated villages. Several families often live together under one roof in a large dwelling called a *long house.* They have vegetable gardens, and they also hunt, fish, and gather edible plants in the nearby jungles.

Most rural villages have one or more small shops run by Chinese merchants, who sell many articles that the people cannot make for themselves. In Sarawak and Sabah, Chinese peddlers travel upriver by boat to isolated settlements to exchange goods for forest products.

City life. Malaysia is rapidly becoming an urbanized society. More than half the population lives in urban ar-

Sepak takraw is a traditional Malay game. Players use mainly their feet to hit a ball over a net. They cannot use their hands.

eas. A lack of jobs in the countryside and an economic boom in the cities have contributed to urban growth.

Kuala Lumpur is a bustling, modern city with lofty skyscrapers, including the Petronas Towers, among the world's tallest buildings. The government created the city of Putrajaya to be Malaysia's administrative capital.

Wealthy Malaysians live in large, comfortable homes with yards and servants. Most urban dwellers, however, live in modest apartments or town houses like those in American and European cities. Many rural Malays who have recently moved to the city live in shacks and other makeshift shelters in temporary squatter settlements.

Clothing. In everyday life, most Malaysians wear clothing similar to that worn in North America and Europe. Nearly all Malays are Muslims, and many of them choose modest styles favored by Islam. For example, many Malay women wear a loose, long-sleeved blouse, a long skirt extending to their ankles, and a shawl or kerchief over their heads. Many Malay men wear a black hat called a *songkok.* For ceremonies and other formal gatherings, both men and women may don traditional Malay dress, which includes a tunic or blouse and a length of *batik* cloth worn as a skirt. Batik is a traditional process of dying cloth in elaborate patterns.

Chinese, Indians, and other groups in Malaysia also wear their traditional dress for special occasions. Many Indian women wear saris, and some Chinese women wear a long, tight-fitting dress called a *cheongsam.*

Food and drink. Rice is the mainstay of the Malaysian diet, supplemented by vegetables, fish, and meat, mainly lamb, mutton, or chicken. Fruit or cake is often served for dessert. Tea and coffee are popular beverages. Two principal ingredients in many Malay dishes are coconut milk and hot chilies. Malaysians also eat many Chinese and Indian dishes, some combined with Malay ingredients to create tasty combinations. Malaysian cities also have fast-food restaurants that serve hamburgers, pizza, and other kinds of American and European foods. Middle-class young people are the chief patrons of such restaurants.

Recreation. Among the Malays, kite flying and top spinning are traditional sports practiced by skilled adults rather than children. *Pencak silat,* the martial art of the Malays, has become part of Malaysian national culture. Silat practitioners fight not only with their hands but also with sticks and knives. *Congkak* is a traditional Malay game of skill using a board with holes and pebbles or marbles. *Sepak takraw* is a popular game like volleyball using a rattan or plastic ball. Unlike volleyball players, however, sepak takraw players use mainly their feet. They cannot touch the ball with their hands.

The most popular Western sports in Malaysia are soccer and badminton. Malaysian teams have won several international badminton championships.

Religion. Malaysia has considerable religious diversity and widespread religious toleration. Muslim mosques, Christian churches, and Hindu and Buddhist temples stand side by side in urban areas. Islam is the religion of almost all Malays, as well as some Malaysian Indians, and is also the official religion of the state. People are allowed to follow other religions but may not try to convert Muslims to their faith. Many Chinese Malaysians are Buddhist, and others are Christian or Taoist. The Kadazans of Sabah and many Ibans of Sarawak are Christian. Most Malaysian Indians practice Hinduism. Many Malaysians make it a custom to participate in the religious holidays of other faiths.

Beginning in the 1970's, an Islamic revival called the *dakwah* movement rapidly gained strength. Most followers of the movement were young, educated urban Muslims. They sought to return to the fundamental beliefs of Islam. They were inspired by Islamic movements in other parts of the world, including the 1979 revolution that established an Islamic government in Iran. The dakwah movement contributed to a growing Islamization of Malaysian life. For example, many Malaysians adopted stricter Islamic standards of dress and behavior.

Education. Primary and secondary education are free. Children start school at 6 years old. They remain in primary school for six years and then go to secondary school. Bahasa Malaysia is the language of instruction in most schools, though some schools, especially at the primary level, also teach in Mandarin Chinese or Tamil. In all schools, English and Bahasa Malaysia are compul-

sory subjects. Malaysia has many universities, technical institutes, and teacher training colleges. The largest university is the University of Malaya at Kuala Lumpur.

The arts. Malaysia has attempted to preserve its traditional art forms despite the immense popularity of American and European rock music, television, and motion pictures. A traditional form of Malay drama is *mak yong* (also spelled *mak yung* or *ma'yong),* in which the performers sing, dance, and act out heroic tales about sultans and princesses. An orchestra called a *gamelan* accompanies most performances. A gamelan consists chiefly of metal percussion instruments, including gongs, xylophones, and drums.

Malaysia has had an active motion-picture industry since the founding of Malay Film Productions in the 1940's. Among the country's most famous stars was an actor, director, producer, singer, and composer named P. Ramlee. Ramlee appeared in films during the 1950's and 1960's.

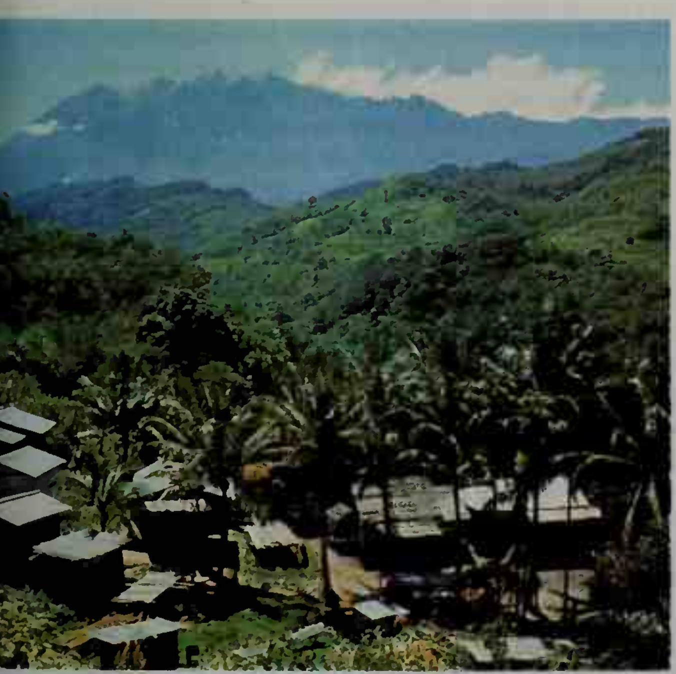
Land and climate

Malaysia has a total area of 127,320 square miles (329,758 square kilometers). Peninsular Malaysia comprises the cities of Kuala Lumpur and Putrajaya and 11 small states, with a total area of 50,810 square miles (131,598 square kilometers). Two much larger states—Sarawak and Sabah—lie on the island of Borneo. Sarawak covers 48,050 square miles (124,449 square kilometers). Sabah—including the small island of Labuan, which is administered separately as part of the Federal Territory of Malaysia—covers 28,460 square miles (73,711 square kilometers). Both the Malay Peninsula and Borneo are heavily forested and mountainous. Mount Kinabalu in Sabah is the highest peak, rising to about 13,431 feet (4,094 meters).

Malaysia has a tropical climate with hot, humid weather that varies little throughout the year. Coastal temperatures range from 70 to 90 °F (21 to 32 °C), while mountain temperatures are usually 55 to 80 °F (13 to 27 °C). Rainfall varies slightly, with heavier downpours from October to April and less rain from May to September. Peninsular Malaysia gets an average of 100 inches (250 centimeters) of rain annually, while Sarawak and Sabah both receive about 150 inches (380 centimeters).

Many animals flourish in Malaysia. They include tigers, wild oxen, water buffaloes, tapirs, orangutans, many varieties of monkeys, cobras, crocodiles, lizards, over 500 kinds of birds, and a vast number of butterflies. Malaysia's plants are equally varied, with many types of wild orchids, tropical fruits, and exotic hardwood trees.

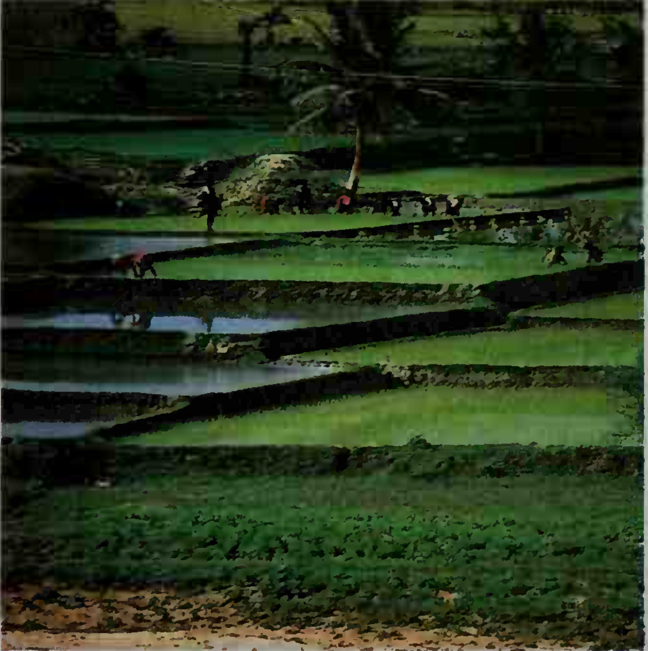
Economy



From the mid-1970's to the mid-1990's, Malaysia had one of the world's fastest growing economies. From 1970 to the mid-1990's, Malaysia's *gross domestic product,* the total value of all goods and services produced within the country, grew at an average annual rate of more than 7 percent. After more than two decades of robust growth, however, the Malaysian economy slowed somewhat in the late 1990's.

Malaysia's impressive economic performance has been based on rich natural resources and a diversified economy. In the 1970's, Malaysia was primarily an exporter of raw commodities, such as timber, rubber, tin, and palm oil. It still produces those basic goods, but they play a much smaller economic role. The country now derives much of its wealth from manufacturing.

Manufacturing employs about one-fourth of Malaysia's labor force and produces about one-third of the gross domestic product. Nearly all manufacturing takes place in the western half of Peninsular Malaysia, chiefly in the Kelang Valley and on the island of Penang.



The Malaysian electronics industry has been a major success. Malaysia is a leading producer of integrated circuits and other semiconductor devices.

Malaysia has also established its own automobile in-

Petroleum production is a major economic activity in Malaysia, and petroleum is the country's chief export. This refinery is in Kerteh, in eastern Peninsular Malaysia. A pipeline links the refinery to offshore wells in the South China Sea.

dustry. With Japanese help, Malaysian automakers began in 1985 to produce a car called the Proton, the first Malaysian-built automobile.

Agriculture. Malaysia is the world's leading producer of palm oil, a vegetable oil made from palm tree nuts. Palm oil is used for cooking and in the production of margarine and soap. Malaysia is also the third-largest producer of natural rubber, exceeded only by Thailand and Indonesia. Nearly all of the country's palm oil and rubber are raised on large plantations for export.

Farmers grow rice, Malaysia's chief food crop, on small farms throughout the country. Malaysian farmers also grow many varieties of tropical fruit, including pineapples, mangoes, and bananas. Two local favorites are the spiky, strong-smelling durian and the juicy, reddish-purple mangosteen. Small farms also produce coconuts, vegetables, and *cacao* (seeds used in making chocolate). Some farmers raise cattle or hogs. Sarawak is one of the world's largest producers of black pepper.

Forestry. Malaysia's tropical rain forests yield many valuable products, including aromatic woods, such as camphor and sandalwood, and beautiful hardwoods, such as ebony, mahogany, and teak.

Mining. Malaysia is rich in mineral resources. The Malay Peninsula has the world's largest reserves of *alluvial tin,* easily mined tin deposits left by flowing water. The country's other minerals include *bauxite* (aluminum ore), copper, gold, and iron ore.

Fishing industry. Malaysian fishing crews take shrimp and such fishes as anchovies and mackerel from Malaysia's coastal waters. Shrimp is the country's most important seafood export.

Service industries, which produce services rather than goods, have become increasingly important to Malaysia's economy. They now employ about half the labor force. The country's main service industries include government, transportation, and retail sales. Most retail stores in Malaysia are small general stores run by Chinese or Indian Malaysians. Larger retail outlets, including supermarkets and department stores, operate chiefly in urban centers. Urban areas also have the bulk of the country's other service industries, such as finance and real estate. Malaysia has a rapidly growing tourist industry that draws millions of visitors a year.

Energy sources. Malaysia is well supplied with energy. Large amounts of oil and natural gas come from offshore wells near the coasts of Terengganu and Sarawak. The heavy rainfall and rugged terrain of Peninsular Malaysia and the Borneo states furnish ample amounts of the falling water needed for hydroelectric power. Plants that burn oil, gas, or coal supply about four-fifths of Malaysia's electric power, and hydroelectric plants generate about one-fifth.

International trade. Malaysia's exports have changed greatly since the 1970's, when rubber and tin dominated. By the 1990's, manufactured goods accounted for more than half of the country's export earnings. Electrical and electronic products, particularly integrated circuits, make up the largest category of manufactured exports. Other major exports include palm oil; petroleum; rubber and rubber products, such as gloves; textiles; and wood products. Malaysia's main imports include chemicals, food, machinery, and transportation equipment. The country's major trading partners are Japan, the United States, and Singapore.

Transportation. Malaysia has a good transportation network, but rapid economic growth has stretched it to the limit. Historically, waterways were Malaysia's primary means of transportation. Even today, water travel remains important because the country's mountainous terrain and thick forests hinder movement by land. Rivers form the main thoroughfare into the interior. The Strait of Malacca, on the western side of the Malay Peninsula, serves as a major shipping lane between Europe and Asia. The South China Sea links the two parts of Malaysia and is the principal thoroughfare between East Asia and Southeast Asia. Malaysia's major seaports include George Town, Port Kelang, and Johor Baharu.

Long-distance travel in Malaysia depends heavily on aviation. Kuala Lumpur International Airport at Sepang is about 30 miles (50 kilometers) south of Kuala Lumpur. This airport opened in 1998 and helped relieve congestion at the older Subang airport. A government-owned airline called Malaysia Airlines is the major Malaysian

air carrier. In 1994, a second national airline called Air Asia began operations.

Since Malaysia's economic boom began in the 1970's, the country's roads have become severely congested. More Malaysians have bought motorcycles and automobiles, adding to traffic congestion. Most middle-class families own cars, especially Malaysian-built Protons. Lower-income groups tend to ride motorcycles or use public transportation. Malaysia has an estimated 58,500 miles (94,000 kilometers) of roads, three-fourths of which are paved.

Buses provide most of Malaysia's public transportation. Railroads, which are owned by the government, operate in Peninsular Malaysia and in Sabah.

Communications. A government-run corporation called Radio Television Malaysia operates radio and television stations. Malaysia also has commercial and cable television stations. Under the Broadcasting Act of 1987, the federal minister of information has the power to monitor all radio and television programming.

Most Malaysian families have a radio or a television set, and most also have a telephone. Cellular telephones are popular among business people and the middle class, and the use of such phones has become a status symbol in modern Malaysia.

Malaysia has about 40 daily newspapers. The most important papers include *Berita Harian* and *Utusan Malaysia* in Bahasa Malaysia and the *New Straits Times* and *The Star* in English.

History

Early days. Scientists have found archaeological evidence of human inhabitants in the Niah Caves in Sarawak from about 40,000 years ago. The earliest evidence of inhabitants on the Malay Peninsula that has been found is from about 10,000 years ago. Most scholars believe the earliest settlers on the Malay Peninsula came overland from southern China in small groups over a period of thousands of years. These early inhabitants became the ancestors of the Orang Asli.

During the 1000's B.C., new groups of migrants who spoke a language related to Malay came to Malaysia. The ancestors of these people had traveled by sea from south China to Taiwan, and later from Taiwan to Borneo and the Philippines. These people became the ancestors of the Malays and the Orang Laut. The newcomers settled mainly in the coastal areas of the peninsula.

About A.D. 1400, a group of Malay-speaking migrants came to the Malay Peninsula from Srivijaya, a trading kingdom on the island of Sumatra (now part of Indonesia). Led by a Sumatran prince called Paramesvara, these newly arrived immigrants established a commercial kingdom called Melaka.

Melaka, also spelled Malacca, became an international center for the spice trade. During the middle and late 1400's, Melaka gained control over much of the Malay Peninsula, Sumatra, and the key shipping route through the Strait of Malacca. It attracted traders from throughout the world.

In the mid-1400's, Melaka became a Muslim kingdom. Islam spread throughout the Malay Peninsula and to other parts of Southeast Asia. Melaka's prosperity drew the attention of the Europeans, who wished to gain control of the valuable spice trade.

Coming of the Europeans. In 1511, the Portuguese seized Melaka from the Malays. The Malays soon moved their center to Johor at the southern end of the Malay Peninsula. Descendants of the ruling family of Melaka also founded other kingdoms on the peninsula.

The Dutch seized Melaka from the Portuguese in 1641 and ruled there for the next 150 years. By the 1700's, the Dutch controlled trade in most of the region.

In 1786, the British acquired Penang Island and established a settlement called George Town there. Gradually, Britain acquired control over more of the area to protect its shipping lanes between China and India. In 1824, the Dutch surrendered to the British their possessions on the Malay Peninsula. In 1826, the British formed a colony called the Straits Settlements that included Melaka and the islands of Penang and Singapore. In 1840, James Brooke, a wealthy English adventurer, helped the sultan of Brunei quiet a local rebellion. In return, the sultan ceded the southern part of his territory, present-day Sarawak, to Brooke in 1841 and bestowed on Brooke the title *rajah.* Brooke and his descendants, called "white rajahs," ruled Sarawak as a self-governing state until the 1940's. In 1881, North Borneo (as Sabah was then called) came under the control of a private trading company called the British North Borneo Company. The British declared North Borneo and Sarawak to be British protectorates in 1888. By 1914, Britain had either direct or indirect colonial control over all the lands that now make up Malaysia, which it called British Malaya.

British rule took several forms. For example, Britain had direct colonial rule in the Straits Settlements, family control by the Brookes in Sarawak, and corporate control in North Borneo. In the kingdoms on the Malay Peninsula, the British governed indirectly, through local rulers. Britain placed a representative called a *resident* in each kingdom. The local sultan agreed to accept the resident's advice on political and economic matters.

To increase its revenues from British Malaya, the British expanded tin mining in the late 1800's. They also introduced rubber trees from Brazil and established rubber plantations in the late 1800's and early 1900's. To provide labor for these enterprises, the British imported

Chinese workers for the tin mines and Indian laborers for the rubber plantations. To help feed the rapidly expanding work force, the British encouraged the Malays to farm for a living.

The British also encouraged ethnic divisions. For example, the British administered the two main ethnic communities in Kuala Lumpur separately through their Malay and Chinese leaders. By hardening the lines that divided the Malays, Chinese, and Indians, these policies helped keep the groups from uniting against the British.

Independence. World War II and its aftermath brought the end of British rule. In that war, Japan, Germany, and the other Axis nations fought against Britain, the United States, and the other Allies. Japan invaded British Malaya in 1941 and occupied it until losing the war in 1945.

Britain dissolved the Straits Settlements in 1946. In 1948, the kingdoms on the Malay Peninsula, plus Melaka and the island of Penang, united to form the Federation of Malaya, a partially independent territory under British protection. Singapore, North Borneo, and Sarawak became separate crown colonies. In 1948, the Malayan Communist Party began a guerrilla uprising against the British that became known as the Emergency. With Malay help, the British finally subdued the Emergency in 1960, three years after independence.

The Federation of Malaya had gained complete independence from Britain in 1957. Singapore, which had a mostly Chinese population, remained outside the federation as a British crown colony.

Building national unity. The first prime minister of the new nation was Tunku Abdul Rahman. Earlier in the 1950's, he and other leaders had formed a political alliance of the three main ethnic parties: the United Malays National Organization, the Malayan Chinese Association, and the Malayan Indian Congress. This three-party partnership, known as the Alliance, was the forerunner of the National Front that is Malaysia's most powerful political organization today.

Dinamika/Information Dept.

Malaya became independent in August 1957. Tunku Abdul Rahman made the declaration and became the country's first prime minister. The country has been called Malaysia since 1963.

In 1963, Singapore, Sabah, and Sarawak joined Malaya to form the Federation of Malaysia. The Malay majority hoped that including Sabah and Sarawak, which had ethnically diverse populations, would balance the large numbers of Chinese from Singapore. Economic and political disputes soon developed between the mostly Chinese state leaders of Singapore and the mostly Malay federal government of Malaysia. In 1965, Singapore withdrew from the federation and became independent.

In Malaysia, as in the former British Malaya, the ethnic groups followed different traditional occupations. The Malays controlled government and agriculture, while the Chinese dominated commerce and industry. The Chinese resented the political power of the Malays, and the Malays envied the economic success of the Chinese. The tensions eventually triggered racial violence. In 1969, bloody riots broke out after an election on Peninsular Malaysia. The government declared a state of emergency, suspending the Constitution and Parliament until 1971.

After the riots, Malaysia's political leaders tried to build national unity. They amended the Constitution to forbid discussion, even in Parliament, of certain "sensitive issues," including the special position of the Malays and of Borneo's ethnic groups, and the powers of the Malay sultans. The amendment also required all government bodies to use Bahasa Malaysia as their principal official language. Many non-Malays, however, resented the government's attempts to build national unity through increased emphasis on Malay culture.

Also after the riots, Malaysia's leaders determined to improve the economic conditions of the Malays. In 1971, they launched a 20-year plan called the New Economic Policy to achieve a better balance of wealth among racial groups. To minimize racial politics, the government created in 1974 a multiparty alliance called the National Front, uniting Malay, Chinese, and Islamic groups.

Recent developments. By the end of the 1990's, the New Economic Policy and its successor, the New Devel-

Important dates in Malaysia

Malcolm X (1925-1965) was one of the most influential African American leaders of the 1950's and 1960's. He transformed himself from a petty criminal into an important defender of the rights of blacks.

Malcolm X was born Malcolm Little in Omaha, Nebraska. His father was a follower of Marcus Garvey, a black leader who worked to establish close political and economic ties to Africa. In 1931, Malcolm's father was found dead after being run over by a streetcar. Malcolm believed white racists were responsible for his father's death. When Malcolm was 12 years old, his mother was committed to a mental hospital. Malcolm spent the rest of his childhood in foster homes. He also became discouraged by racial prejudice around him.

In 1941, Malcolm moved to Boston. The youth became involved in criminal activities. In 1946, he was arrested for burglary and sent to prison. In prison, he joined the Nation of Islam, commonly called the Black Muslims. The Nation of Islam taught that white people were devils. After Malcolm was released from prison in 1952, he adopted *X* as his last name. The letter stood for the unknown African name of Malcolm's slave ancestors.

Frank Castoral, Photo Researchers
Malcolm X

Malcolm X quickly became the Nation of Islam's most effective minister. He was a fiery orator, urging blacks to live apart from whites and to win their freedom "by any means necessary." But he became dissatisfied with the Nation of Islam, in part because it avoided political activity.

In 1964, Malcolm X broke with the Nation of Islam. Soon afterward, he traveled to the Muslim holy city of Mecca in Saudi Arabia. He met Muslims of many ethnic backgrounds and rejected the view that all white people are devils. Malcolm X adopted the Muslim name El-Hajj Malik El-Shabbazz. After returning to the United States, he formed his own group, the Organization of Afro-American Unity.

Malcolm X rejected nonviolence as a principle, but he sought cooperation with Martin Luther King, Jr., and other civil rights activists who favored *militant* (aggressive) nonviolent protests. But by this time, some Black Muslims had condemned Malcolm X as a hypocrite and traitor because of his criticisms of the group's leader, Elijah Muhammad. On Feb. 21, 1965, Malcolm X was fatally shot while giving a speech in New York City. Three members of the Nation of Islam were convicted of the crime. Malcolm's views reached many people after his death through his *Autobiography of Malcolm X* (1965).

Maldives, *MAWL deevz* or *MAL dyvz,* is the smallest independent country in Asia and one of the smallest in the world. It consists of about 1,200 small coral islands that form a chain 475 miles (764 kilometers) long and 80 miles (129 kilometers) wide in the Indian Ocean. The northern tip of the Maldives is about 370 miles (595 kilometers) south of India. These tropical islands cover a to-

Maldives

WORLD BOOK maps

tal of only 115 square miles (298 square kilometers). Fishing and tourism are the main economic activities.

The United Kingdom governed the Maldives as a protectorate for 78 years. The islands became independent in 1965. The official language is Dhivehi, and the country's name in that language is *Dhivehi Raajjeyge Jumhooriyyaa* (Republic of Maldives). Male is the capital and largest city.

Government. The Maldives is a republic. The president, who is head of the government, is elected to a five-year term by the *Majlis* (legislature). A nine-member Cabinet assists the president. The 48 members of the Majlis serve five-year terms. The people elect 40 members, and the president appoints 8. An elected committee handles local government on each *atoll* (cluster of islands). The government appoints a *kateeb* (head official) for each island. A chief justice appointed by the president administers the laws. Law in the Maldives is based on the Sunni Muslims' code of law.

People. Most Maldivians are descendants of Sinhalese people who came from Sri Lanka. Some Maldivians are descendants of people from southern India and Arab traders and sailors. Almost all Maldivians belong to the Sunni division of Islam. Maldivians live on only about 200 of the country's islands. About 80 islands are reserved for tourists.

Many Maldivians go to sea every day in boats to catch fish. Most build their boats of coconut or other timber that grows on the islands. Each boat can hold about a dozen crew members. The fishing crews sail 15 or 20 miles (24 or 32 kilometers) out from the islands, and catch bonito, tuna, and other fish. Most of the fish are exported to Japan and Sri Lanka.

Fish is the primary food of the people of Maldives. They also eat coconuts, papayas, pineapples, pomegranates, and sweet potatoes.

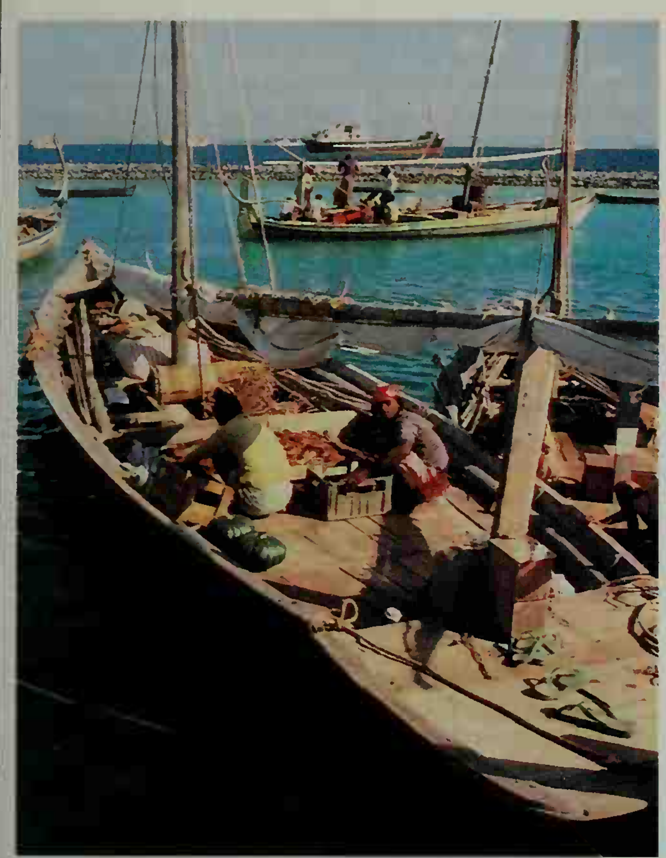
Land. The 1,200 small islands are grouped together in 13 major clusters called *atolls*. Barrier reefs around the atolls help protect the islands from the sea.

None of the islands covers more than 5 square miles (13 square kilometers), and most are much smaller than that. Most are like little platforms about 6 feet (1.8 meters) above sea level. An 8-foot (2.4-meter) elevation on Wilingili Island is the highest point. The islands have clear lagoons and white sand beaches. The land is covered with grass and low-growing tropical plants. Coconut palms and fruit trees grow on the islands.

The climate is hot and humid. Daytime temperatures average about 80 °F (27 °C). The northern islands receive at least 100 inches (250 centimeters) of rain a year, and those in the south receive almost 150 inches (381 centimeters). Two *monsoons* (seasonal winds) blow over the islands each year and bring most of the rain.

Economy of the Maldives depends largely on fishing and tourism. The government controls the fishing industry, and the sale of dried fish in Sri Lanka is one of the chief sources of government income. About one-fifth of the national income comes from tourism.

Maldivians raise breadfruit, chili peppers, coconuts, millet, and sweet potatoes. Craftworkers use the coconut husk fibers, called *coir*, to make yarn and ropes. Gan Island has two large clothing factories that produce shirts and sweaters.



Fish is the Maldives' chief export. Other exports include coir yarn, *copra* (dried coconut meat), cowrie shells, and fish meal. Rice, sugar, wheat flour, and manufactured goods are the major imports. India, Japan, Singapore, and Sri Lanka are the country's chief trading partners.

Sailboats are the most common form of transportation in the Maldives. Steamships sail regularly between Male and Sri Lanka.

History. Little is known about the early history of the Maldives, but people have lived there for thousands of years. The islands came under Portuguese rule during the 1500's. From 1656 to 1796, the Dutch ruled the

Facts in brief

Capital: Male.
Official language: Dhivehi.
Total land area: 115 mi² (298 km²). *Greatest distances*—north-south, 550 mi (885 km); east-west, 100 mi (161 km).
Elevation: *Highest*—8 ft (2.4 m) above sea level, on Wilingili Island. *Lowest*—sea level.
Population: *Estimated 2002 population*—302,000; density, 2,626 per mi² (1023 per km²); distribution, 75 percent rural, 25 percent urban. *1995 census*—244,814.
Chief products: *Agriculture*—chili peppers, coconuts, millet, sweet potatoes. *Fishing*—bonito, tuna. *Handicrafts*—coir yarn, cowrie shells, shirts and sweaters, woven mats.

Bernard Regent, Hutchison Library

Fishermen in the Maldives catch mainly tuna and bonito. Fish, one of the nation's leading foods, is also the chief export.

islands. In 1887, the Maldives officially became a British protectorate. The Maldives had internal self-government, but the United Kingdom handled foreign affairs.

In the 1950's, a dispute between the Maldivians and the British over an air base on Gan Island led to the *secession* (withdrawal) of three southern atolls. The Maldivian government accused the United Kingdom of backing the rebellion, which it crushed in 1960. That same year, the United Kingdom and the Maldives signed an agreement that gave the British free use of the Gan Island base. The Maldivians received the right to conduct most of their foreign affairs and about $2 million for economic development. In 1965, the United Kingdom and the Maldives signed a new agreement that gave the islands complete independence.

The Maldives became a republic in November 1968. In 1976, the British withdrew from the Gan Island air base. The Maldives joined the Commonwealth of Nations in 1982. In 1985, the Maldives and six other countries established the South Asian Association for Regional Cooperation (SAARC), a regional association that deals with social and economic issues. The other countries are Bangladesh, Bhutan, India, Nepal, Pakistan, and Sri Lanka. Robert W. Bradnock

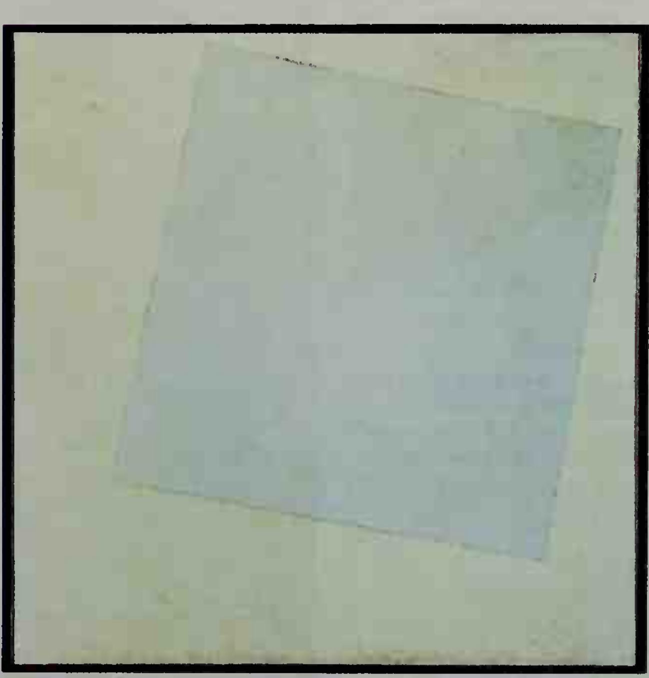
Male. See **Reproduction; Sexuality.**

Male, *MAH lay* (pop. 56,060), is the capital and chief port of the Maldives. It lies on Male Island, in the Indian Ocean. For location, see **Maldives** (map).

Housing in Male ranges from palm thatched structures with tin roofs to buildings made of crushed coral with tile roofs. Male has many *mosques* (Islamic houses of worship). Its landmarks include the Islamic Center, a gold-painted mosque and meeting place. The national museum, on the grounds of the demolished sultan's palace, displays items from Arab, Dravidian, and Sri Lankan cultures. Male attracts many tourists. Tourist and government activities employ many of the city's people.

The origin of Male is unknown. But it may have been founded as the capital when the first people reached the Maldives in the 300's B.C. Robert LaPorte, Jr.

Malemute. See **Alaskan malamute.**



Malenkov, *MAH luhn KAWF* or *mah lehn KAWF,* **Georgi Maximilianovich,** *gay AWR gih MAH ksih mih LYAH nah vihch* (1902-1988), became premier of the Soviet Union after the death of Joseph Stalin in March 1953. Nikita S. Khrushchev forced him to resign as premier in February 1955, and Malenkov became deputy premier under Premier Nikolai Bulganin. In June 1957, Malenkov tried to unseat Khrushchev as first secretary of the Soviet Communist Party. He failed and was sent to Kazakhstan. He was expelled from the party in 1964.

Malenkov was born on Jan. 13, 1902, in Orenburg. He became Stalin's private secretary in 1925. He became a member of the Politburo in 1946, and second secretary of the Presidium in 1952. Malenkov died on Jan. 14, 1988.

Albert Marrin

Malevich, *muhl YAY vihch,* **Kasimir,** *KAZ uh mir,* (1878-1935), was a Russian artist who pioneered abstract painting in Russia. Malevich developed a style called Suprematism, which reduced painting to its essential elements, such as color, line, and shape.

Malevich's Suprematist paintings consist of one or more geometric forms on a white background. Each form is *monochrome* (in a single color), usually black or red. In *Suprematist Composition: White on White* (about 1918), a white square floats in a white background. The square and the background are distinguishable only through slight differences in tint and the direction of the

Suprematist Painting: White on White (about 1918), an oil painting on canvas; the Museum of Modern Art, New York City

A Malevich painting shows the artist's dedication to the purity of geometric forms. The painting consists of a single white square on a background of a slightly different white.

brush strokes. The theory of supremacy is based on Malevich's belief in "the supremacy of pure feeling" in art.

Malevich was born of Polish parents near Kiev, Ukraine, which was then controlled by Russia. Malevich created his first suprematist work, a black square on a white background, in 1913. The first exhibition of suprematist works was in 1915. Deborah Leveton

Malherbe, *mal EHRB,* **François de,** *frahn SWAH duh* (1555-1628), was a French poet who became a haughty critic of French poetic language and style. He ridiculed the French poets of the 1500's, mercilessly attacking their flowery vocabularies and elaborate sentences. Some scholars believe that Malherbe smothered French lyric poetry by setting rigid rules that dominated poets until the Romantic period of the early 1800's. But he also gave the language simplicity, clarity, force, and dignity.

Malherbe insisted that poetry be understandable, even to the poorest people of Paris. But he sternly avoided expressing personal feelings. Instead, Malherbe wrote about love and death, the great moral truths, and patriotic subjects of his day. His poetry consists of *Odes* and *Stanzas* (1600-1628). Malherbe was born in Caen.

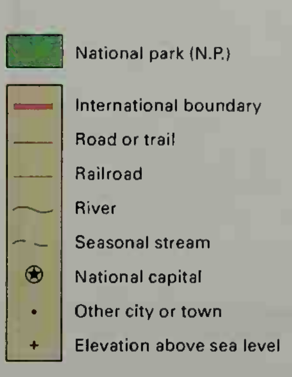
Robert B. Griffin

Mali, *MAH lee,* is a large country in western Africa. The Sahara, Africa's great desert, covers the northern half of the country. Rolling grassland spreads across most of the rest of Mali.

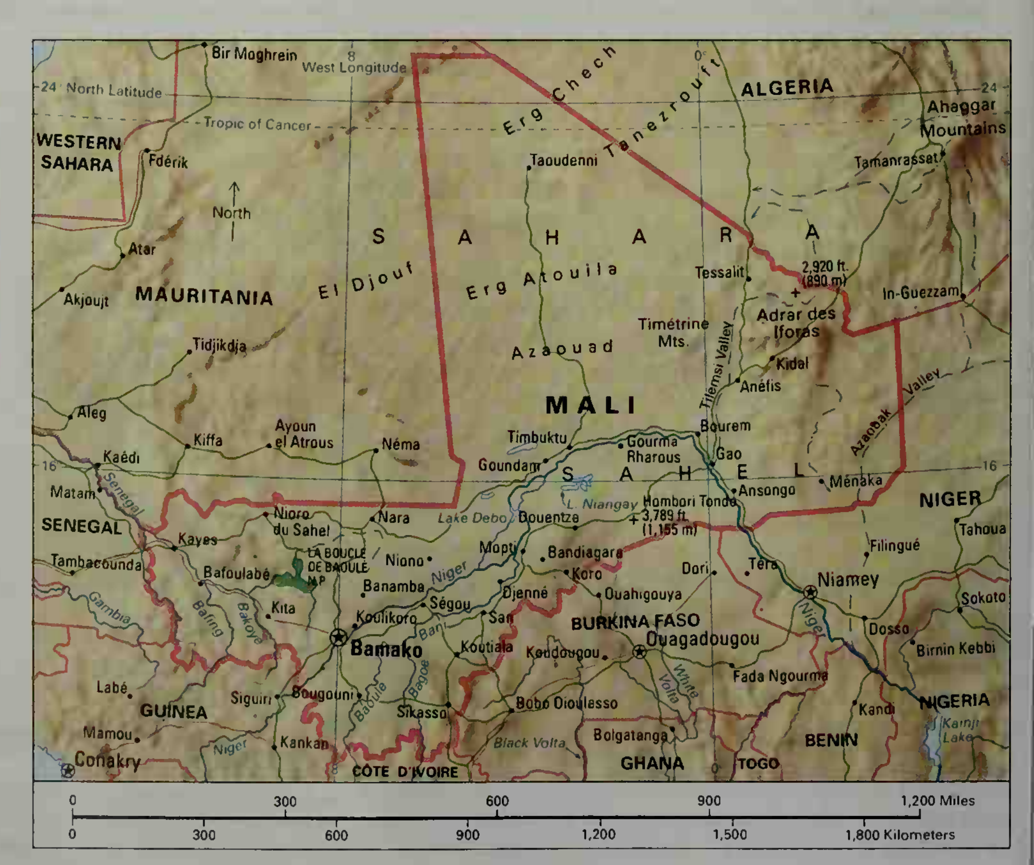
Mali is a poor, agricultural country. At times, droughts have led to large numbers of deaths of people and animals there. Most of Mali's people are black Africans who live in small rural villages and farm for a living. Many of the country's farmers produce only enough food for their own families. Many others raise livestock in the desert. Mali has a variety of mineral and water resources, but they are largely undeveloped. Manufacturing and mining contribute relatively little to Mali's economy.

From about the A.D. 300's to the late 1500's, one or more of three powerful black empires—Ghana, Mali, and Songhai—thrived in what is now Mali. France ruled Mali from 1895 to 1959. Mali became an independent nation in 1960. Its name in French, the official language, is République du Mali (Republic of Mali). Bamako is Mali's capital and largest city.

Government. The president, Mali's top government official, is elected by the people to a five-year term. The president may serve a maximum of two terms. The president appoints a prime minister and other government ministers, who carry out the day-to-day operations of the government. Mali has a 147-member legislature called the *National Assembly.* The members are elected by the people.



Mali's court system includes a Supreme Court, a Constitutional Court, and lower courts. For purposes of local government, Mali is divided into eight regions and the District of Bamako.



People. The vast majority of Mali's people are black Africans. The Fulani and a related people called the Toucouleur make up the largest group of Mali's people. The Fulani are descended from both blacks and whites. The Mandingos form the next largest Malian group. There are three main Mandingo subgroups—the Bambara, Malinke, and Soninke. Other large black groups in Mali include the Dogon, Songhai, and Voltaic peoples. Whites account for about 5 percent of Mali's population. The whites include Arabs, Europeans—chiefly French—Moors, and Tuareg.

The Fulani and Toucouleur speak Fulani. Most of

Mali

WORLD BOOK maps

Facts in brief

Capital: Bamako.
Official language: French.
Area: 478,841 mi^2 (1,240,192 km^2). *Greatest distances*—east-west, 1,150 mi (1,851 km); north-south, 1,000 mi (1,609 km). *Coastline*—none.
Elevation: *Highest*—Hombori Tondo, 3,789 ft (1,155 m) above sea level; *Lowest*—75 ft (23 m) above sea level, at the western border.
Population: *Estimated 2002 population*—11,810,000; density, 25 per mi^2 (10 per km^2); distribution, 74 percent rural, 26 percent urban. *1987 census*—7,696,348.
Chief products: *Agriculture*—cassava, corn, cotton, livestock, millet, peanuts, rice, sorghum, sugar cane, yams. *Fishing*—carp, catfish, perch. *Manufacturing*—food products, leather products, textiles. *Mining*—salt, gold.
Flag: The flag has vertical stripes of green, gold, and red. The stripes symbolize devotion to a republican form of government and the Declaration of the Rights of Man. See **Flag** (picture: Flags of Africa).
National anthem: "A Ton Appel Mali" ("At Your Call Mali").
Money: *Basic unit*—franc.

Mali's other people speak Bambara or other local languages. The Arabs and Moors speak Arabic, and the Tuareg use an ancient Berber language. French is spoken mainly by the Europeans, and by people in government offices and schools.

Islam is the chief religion in Mali. About 65 percent of the people are *Muslims* (followers of Islam). The Bambara, Malinke, and Voltaic peoples practice traditional African religions. About 5 percent of the people are Christians.

Most of Mali's black African population reside in small rural villages in the southern part of the country and grow crops for a living. They generally work on village-owned plots. Many can raise only enough food for their own use. Their foods include cassava, corn, millet, rice, sorghum, and yams. Most Malian farmers cannot afford agricultural machinery, and so they use hand tools for almost all their work. Most village families live in small houses made of mud or branches.

A majority of Mali's Fulani farm for a living. They live in dome-shaped houses thatched with straw and lined with mats. Others raise cattle in the Sahel, a semidesert region, and in the southern grasslands. These herders live in low shelters made of straw mats or branches.

Many of Mali's Arabs and Moors and almost all the Tuareg are nomads. The nomads herd cattle, goats, sheep, and donkeys back and forth across the Sahel and Sahara in search of water and pasture for grazing. They live in portable tents made of camel hair. Their basic foods include dates and millet. The nomads travel in groups led by *marabouts* (holy men) and are fiercely independent. They are more loyal to their marabouts than to Mali's government.

Many of Mali's Europeans are descendants of French colonists. Most live in modern houses in Bamako and other urban areas. Bamako is Mali's largest city (see **Bamako**). Many Europeans own businesses or have government or professional jobs. Others work in banks, stores, and offices.

Women play a key role in farming in Mali. They help plant and harvest crops and raise livestock. The government has set up modern job training programs for women. But relatively few have enrolled because of their heavy workloads and family responsibilities.

Mali, like other developing nations, faces major social problems. Many of its people suffer from a lack of education. Most of Mali's adults cannot read and write, and many of the country's school-age children do not attend school. For Mali's literacy rate, see **Literacy** (table: Literacy rates for selected countries). Mali has several schools of higher education. But many Malian students prefer to get higher degrees and professional training in other nations, mainly France and Senegal.

Mali is also challenged by poor health conditions. The average life expectancy for infants in the country is less than 50 years. Approximately a fifth of the babies born in rural areas die as infants. Malaria is widespread in Mali and is a chief cause of death among children. Mali has only a few hundred doctors to serve its entire population. Most of them work in urban areas.

Wendy Watriss, Woodfin Camp, Inc.

A street market stretches along a sidewalk in Bamako, Mali's capital and largest city. Such markets serve as social centers as well as places to buy or trade food and other goods.

Carl Purcell, Click/Chicago

Nomads camp in a desert area of Mali. They travel with their herds in search of grazing land and water. The dry Sahara covers much of the northern part of the country.

Wendy Watriss, Woodfin Camp, Inc.

Vast grasslands stretch across much of southern Mali. This area receives abundant rainfall and supports many kinds of wild animals, including elephants, giraffes, and lions.

Land and climate. Mali has three main land regions: the harsh Sahara in the north, the semidesert Sahel in central Mali, and rolling grasslands in the south. Mali has few mountains. Its highest point, Hombori Tondo, a mountain in the south, rises 3,789 feet (1,155 meters) above sea level.

The Sénégal and Niger are Mali's chief rivers. Most of the country's people live in villages and urban areas along or near these rivers and their branches. The Sénégal flows through southwestern Mali. The Niger enters Mali near Bamako and flows northeastward into the interior delta, Mali's most fertile area. It then makes a great turn called the Niger Bend and flows southeastward into the country of Niger. It spreads out into a network of branches and lakes in Mali.

Mali has three seasons. Its weather is hot and dry from March to May, warm and rainy from June to October, and relatively cool and dry from November to February. Average annual temperatures are between 80 and 85 °F (27 and 29 °C) in much of the country. From March to May, temperatures often exceed 100 °F (38 °C). In the scorching Sahara, they may rise to more than 110 °F (43 °C) during the day. But at night, Sahara temperatures may be as low as about 40 °F (4 °C). The Sahara receives an average of about 10 inches (25 centimeters) of rain a year, and southern Mali averages about 35 inches (89 centimeters).

Animal and plant life. Many wild animals roam across southern Mali. These animals include elephants, gazelles and other antelope, giraffes, hyenas, leopards, and lions. Crocodiles and hippopotamuses live in the river areas.

Mali has a variety of plant life. Trees scattered throughout the southern grasslands include cailcedra, kapioka, karite, and nere. The Sahel has baobab, down palm, and palmyra trees. It also supports acacia, cram-cram, mimosa, and other short, thorny plants.

Economy. Mali is a poor country with a developing economy. More than three-fourths of its workers farm or herd livestock for a living. Millet, rice, and sorghum are the main food crops. Other food crops include cassava, corn, and yams. Cotton, peanuts, and sugar cane are important cash crops. Nomads raise large herds of cattle, goats, and sheep. Fishing is also an important economic activity. The largest catches are carp, catfish, and perch. The fish come mainly from the Bani and Niger rivers and Lake Debo.

Service industries, such as government, tourism, and wholesale and retail trade, employ about 15 percent of Mali's labor force. Most of these people work in Bamako and other urban areas.

Manufacturing provides jobs for about 10 percent of the workers. The production of textiles is the leading manufacturing activity. The production of food and leather products is also important. The government owns almost all big factories but encourages increased private enterprise. Most of the country's largest industrial plants were built with foreign aid. They include a cement factory, sugar mill, tannery, and textile plant.

Mali has deposits of bauxite, copper, gold, iron ore, manganese, phosphates, salt, and uranium. However, the production of salt is the only major mining activity. Some gold is produced.

Cotton is Mali's chief export. It earns about half the country's export income. Mali also exports fish, leather products, livestock, meat, and peanuts. Its leading imports include chemicals, food, machinery, petroleum, and textiles. Mali trades chiefly with other countries of western Africa, and with France and other Western European nations.

Mali has about 11,200 miles (18,000 kilometers) of roads, but only about 10 percent are paved. The Niger River is navigable throughout its course in Mali. A railroad links Bamako and Dakar, Senegal. Air Mali, the national airline, operates in Mali and has flights to other African countries and to Europe.

Mali has 3 daily newspapers, about 40 radio stations, and 3 television stations. The government publishes one of the newspapers and operates one each of the radio and TV stations. The rest are privately owned.

Mali faces several economic problems. It depends heavily on agriculture, but only about a fifth of its land is fertile. The government at times discouraged farming by keeping food prices low. Crop production has also frequently suffered from below normal rainfall. In addition, pasture for grazing became increasingly scarce. In the

1970's and early 1980's, severe droughts destroyed much of the plant life in the Sahel and caused the death of millions of cattle, goats, and sheep. Mali's economy also has been troubled by sharp drops in world cotton prices and large increases in the cost of imported petroleum and other fuels.

History. From about the A.D. 300's to the late 1500's, areas in what is now Mali formed part of one or more of three great black empires. These empires—Ghana, Mali, and Songhai—grew prosperous because they controlled important trade routes.

The Ghana Empire began during the 300's and lasted until the mid-1000's. It became known as "the land of gold" because traders brought gold there from fields farther south and exchanged it for salt and other goods from North Africa. See **Ghana Empire**.

The Mali Empire flourished from about 1240 to 1500. In the 1300's, it ranked as the wealthiest and most powerful state in western Africa. Mansa Musa, its king from 1312 to 1337, brought Muslim scholars to the empire, and the city of Timbuktu started to become a center of Muslim learning. See **Mali Empire; Timbuktu**.

The Songhai Empire began in the 700's. The Malian city of Gao served as capital of the empire. Under Askia Muhammad, who ruled the empire from 1493 to 1528, Timbuktu reached its peak as a center of wealth and Muslim learning. Invaders from Morocco overran Songhai in 1591. Many small kingdoms later ruled the area. See **Songhai Empire; Askia Muhammad**.

During the mid-1800's, France tried to set up a colony in what is now Mali. But French troops met fierce resistance from black Africans and did not gain control of the area until 1895. In 1904, the colony, then called French Sudan, became part of French West Africa. In 1946, France gave French Sudan the status of a territory in the French Union. See **French West Africa**.

In 1958, French Sudan became a self-governing republic within the French Community. The next year, French Sudan and Senegal united to form the Federation of Mali. Modibo Keita, a Malian leader, became head of the federation. The federation broke up in August 1960. On Sept. 22, 1960, French Sudan gained complete independence as the Republic of Mali.

Keita became Mali's first president. He tried to develop the economy, partly by establishing close ties with the Soviet Union and other Communist nations. Several Communist countries built factories in Mali. But worldwide inflation and an unsuccessful attempt to set up a new money system led Mali into debt.

In 1968, a group of Malian military leaders overthrew Keita. Moussa Traoré, one of the leaders, took control of Mali's government as head of a military committee.

In 1974, Malians approved a constitution that called for the gradual establishment of an elected president and legislature. Legislative and presidential elections—the first elections under the Constitution—were held in 1979. All the candidates belonged to the Mali People's Democratic Union. Traoré, who headed the party, was elected president.

In the 1970's and early 1980's, severe droughts struck the Sahel and brought widespread famine to Mali. Millions of cattle, goats, and sheep died. Thousands of Fulani and Tuareg herders, who depended on their livestock for meat and milk, died from malnutrition. Thousands of other nomads poured into Mali's urban areas seeking food. The United Nations and a number of countries gave Mali food to prevent mass starvation.

Today, Mali's lack of industry and heavy reliance on agriculture limit economic progress. Malians are working to establish a more balanced economy to lessen the economic disasters caused by droughts and other agricultural problems.

In 1991, Malian government forces killed many people in a crackdown against antigovernment protests. Later that year, military leaders overthrew Traoré's rule and formed a temporary government composed of military and civilian members. In 1992, a new constitution was adopted. It provided for a multiparty system and an elected government. A new civilian president, Alpha Oumar Konaré, was elected. A new National Assembly was also elected. In 1993, former President Traoré was tried and convicted for his government's actions against the protests of 1991. In 1997, Konaré was reelected president. In 1999, Traoré was convicted of embezzlement. In 2002, Amadou Toumani Touré was elected president. Touré had helped lead the overthrow of Traoré in 1991. Shortly before leaving office in 2002, Konaré granted Traoré full pardon for his crimes. Clement Henry Moore

Mali Empire, *MAH lee,* was a black empire that flourished in west Africa from about 1240 to 1500. At its height, the Mali Empire controlled most of what are now Gambia, Guinea, Mali, and Senegal, and parts of present-day Burkina Faso, Mauritania, and Niger.

Between 1235 and 1240, Sundiata, the king of Kangaba, conquered the nearby lands of the Sosso. He built a

WORLD BOOK map

new city, Niani, to be the capital of his empire (see **Sundiata Keita**). Later, under Mansa Musa, who ruled from 1312 to about 1337, the empire spread eastward to Gao. Mansa Musa brought the empire to the peak of its political power and cultural achievement. Timbuktu became a famous center of learning, especially in law and the study of Islam, the Muslim religion.

The cities of the Mali Empire were centers for the caravan trade from beyond the Sahara. The people were successful farmers and herders. Members of the governing classes were Muslims, but most of the people continued to worship traditional local African gods.

Control of the vast empire required skill and power that Mansa Musa's successors lacked. After about 1400, Songhai and other states conquered Mali's outlying areas. By 1500, the Songhai Empire controlled most of the Mali Empire. Leo Spitzer

Malignancy, *muh LIHG nuhn see,* is the tendency of a disease to be severe and possibly cause death. It most frequently refers to a *malignant tumor,* or cancer, in contrast to a *benign* (mild) tumor (see **Cancer**; **Tumor**). Benign tumors remain in one part of the body and grow slowly. Malignant tumors can invade surrounding normal tissue, or spread to distant organs of the body through the blood, a process called *metastasis.* Malignant cells often resemble the normal cells that they originate from, but they have unique characteristics that make them malignant. Many people say *malignancy* when they mean *cancer.* Joseph V. Simone

Malinke. See **Mandingo**.

Malinowski, *MAH lih NAWF skee,* **Bronislaw,** *braw NEE slahf* (1884-1942), was a British anthropologist. He became known for his study of the culture of the peoples of the Trobriand Islands in the southwest Pacific, and for his contributions to theories on human culture.

Malinowski was born on April 7, 1884, in Poland. He taught at the University of London and at Yale University. He wrote *Argonauts of the Western Pacific, Sexual Life of Savages in North West Melanesia,* and *Coral Gardens and Their Magic.* David B. Stout

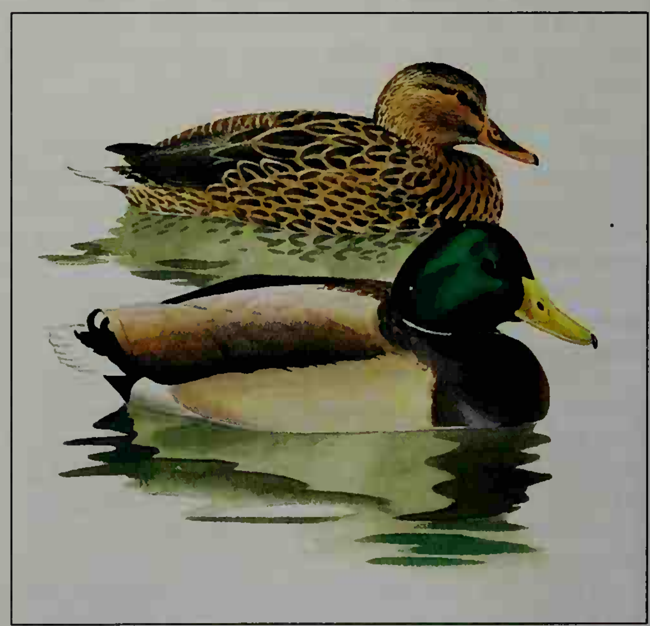
Mall. See **Shopping center**.

Mallard is one of the most common wild ducks. It lives in shallow wetlands in many parts of the world. It also inhabits areas near people, such as city parks. Mallards grow 20 to 28 inches (51 to 71 centimeters) long. In the breeding season, the male possesses striking colors, including a glossy green head, a white neck ring, a chestnut breast, and black feathers on part of the tail. The female has duller, brownish feathers that camouflage her while on her nest. The male loses his bright-colored feathers after mating and becomes similar in appearance to the female. He later replaces his mating feathers.

During warmer months, mallards nest chiefly in ponds and other prairie wetland habitats. They migrate to warmer climates in winter. Most mallards nest on the ground. The females usually lay 8 to 12 eggs. The males flock together after the eggs are laid, and the young are cared for by the females alone. Mallards feed chiefly on small water animals, such as insects, snails, and crustaceans, during early summer. They eat mainly seeds and plants the rest of the year. Rodger D. Titman

Scientific classification. The mallard belongs to the family Anatidae. Its scientific name is *Anas platyrhynchos.*



See also **Duck** (picture).

Mallarmé, *mah lahr MAY,* **Stéphane,** *stay FAHN* (1842-1898), a French poet, became the master of a group of poets who began a movement called *symbolism.* Mallarmé systematically made his poems obscure, refusing to communicate directly with readers. In "The Tomb of Edgar Poe" (1877), he rejected what he called "the words of the tribe"—that is, normal, everyday language. Key words in his poems have several simultaneous meanings and must be interpreted with a dictionary. Mallarmé's prose is remarkable for its vitality and complex sentence structure. His writings had an enormous influence on literary criticism in the late 1900's.

Mallarmé is best known for his poem "L'Après-midi d'un faune" ("The Afternoon of a Faun," 1876). This dramatic monologue explores the fine lines that separate dream, fantasy, and reality. Mallarmé's ambition was to write a "total book," a long work that he said would provide an "Orphic explanation of the earth." Two fragments exist from this unfinished work, the metaphysical dream meditation called *Igitur* and the poem "A throw of the dice will never abolish chance." Mallarmé was born on March 18, 1842, in Paris. Edward K. Kaplan

Malleability, *MAL ee uh BIHL uh tee,* is the ability of many metals to be pressed or hammered into thin sheets. A malleable metal can be squeezed into a thin sheet by pushing on it in opposite directions. The most malleable metals include copper, gold, and silver. For example, gold can be shaped into foils 10 times as thin as a sheet of paper. Some gold foils measure only 0.0001 inch (0.00254 millimeter) thick. Certain metals are unmalleable at room temperature but gain malleability when heated and kept at a high temperature. Malleable metals also exhibit *ductility*—that is, they can be permanently stretched to a considerable degree without breaking. See also **Ductility**; **Elasticity**. Johannes Weertman

Mallory, *MAL uh ree,* **Stephen Russell** (1813?-1873), was secretary of the Confederate Navy during the Civil War (1861-1865). He was born on the Caribbean island of Trinidad but grew up in Key West, Florida.

Mallory was appointed inspector of *customs* (import taxes) in Key West in 1833. In 1845, United States President James K. Polk appointed him collector of customs in Key West. In 1850, Mallory was elected to the U.S. Senate from Florida.

Florida *seceded* (withdrew) from the Union in 1861, and Mallory resigned from the Senate. Confederate President Jefferson Davis appointed him secretary of the Navy, which was then almost nonexistent. Mallory had to organize the Navy and direct it. He also had to build and equip ships from what little material he found available. Mallory succeeded in building a small but efficient Navy and showed much foresight in ordering ironclads built instead of the older type of wooden warships. His naval experts developed deadly torpedoes and underwater devices which kept the Union Navy out of the great rivers of Virginia until late in the war.

After the fall of Richmond, Virginia, in 1865, Mallory fled south with President Davis and was captured in Georgia. He was held prisoner for nearly a year but was pardoned by U.S. President Andrew Johnson in 1867. He then practiced law in Pensacola, Florida. Michael Perman

Mallow, *MAL oh,* is the popular name of a large family of plants. This family includes about 1,000 kinds of trees, herbs, and shrubs that grow in tropical and temperate regions of the world. Plants in this family have fibrous stems and sticky sap. They bear flowers with many *stamens* (male reproductive parts) that are fused together into a tubelike structure. The hibiscus, hollyhock, and marsh mallow all belong to the mallow family. The cotton plant and okra also are members. Walter S. Judd

Scientific classification. Mallows make up the mallow family, Malvaceae.

Cotton	Marsh mallow
Flowering maple	Okra
Hibiscus	Velvetleaf
Hollyhock	

Malmö, *MAL moh* or *MAHL muh* (pop. 237,438), is the third largest city in Sweden. Only Stockholm and Göteborg have more people. Malmö lies at the southern tip of Sweden, across the Öresund strait from Copenhagen, Denmark. For location, see Sweden (political map).

Malmö is southern Sweden's center of commerce and transportation. The Öresund Link runs between Malmö and Copenhagen. Both automobiles and railroad trains cross the bridge-and-tunnel link. Malmö's highways, railways, and airport provide other transportation links. The city's main economic activities include engineering and service industries, food processing, and the production of cement, handicrafts, and textiles.

Malmöhus Castle, a medieval fortress surrounded by a moat, is a popular attraction. It contains art and natural history museums and an aquarium.

Danish merchants founded Malmö in the 1100's, when the area was part of Denmark. Sweden forcibly annexed the area in 1658. M. Donald Hancock

Malnutrition, *MAL noo TRIHSH uhn,* is an unhealthy condition caused by a poor or inappropriate diet or by the body's inability to absorb or use nutrients. *Primary malnutrition* results when the body gets too much food, not enough food, or the wrong kinds of food. *Secondary malnutrition* occurs when, because of disease, the body cannot use the nutrients that are present in food.

There are a number of types of malnutrition. Obesity and starvation are extreme forms. Obesity occurs when people eat much more food than they need. Undernutrition or starvation occurs when a person does not get enough food or does not consume enough of a particular nutrient or nutrients. Symptoms of undernutrition and starvation include cramps, diarrhea, weakness, and weight loss. *Protein-energy malnutrition,* also called *protein-calorie malnutrition,* occurs when a diet is low in both proteins and calories. This condition is called *marasmus* if a diet is particularly low in calories. It is called *kwashiorkor* if a diet is especially low in proteins.

Malnutrition caused by a low intake of vitamins may lead to *vitamin deficiencies.* Various diseases result from deficiencies of different vitamins. Malnutrition may also be due to *mineral deficiencies.* For example, lack of iron or copper can cause an abnormal condition of the blood called *anemia.* Social and economic conditions as well as natural disasters such as flooding and drought may produce malnutrition. Poverty, war, disease, and ignorance regarding a balanced diet also cause countless cases of malnutrition. Mary Frances Picciano

Malone, Karl (1963-), ranks among the most dominant power forwards in basketball history. He is second among career scorers in the National Basketball Association (NBA), behind only Kareem Abdul-Jabbar. Malone is known for his strength and his ability to both score and rebound. He holds the NBA record for most free throws made in a career and most consecutive seasons in the NBA scoring at least 2,000 points.

Malone has played his entire professional career with the Utah Jazz of the NBA. He is also one of the most durable players in NBA history. He missed only four games his first 12 seasons with the Jazz. Malone won the NBA's Most Valuable Player award for the 1996-1997 and 1998-1999 seasons. In 1997, he was named to the NBA's 50th anniversary team of the league's 50 top players.

Malone was born July 24, 1963, in Summerfield, Louisiana. He starred at Louisiana Tech University for three seasons before turning professional in 1985. Utah drafted him as the 13th selection in the first round. He played on the United States teams that won the gold medal at the 1992 and 1996 Summer Olympic Games. Sam Smith

Malory, *MAL uh ree,* **Sir Thomas** (? -1471?), was the author of the book *Le Morte Darthur.* This title is French for *The Death of Arthur.* In the book, Malory told the whole story of King Arthur of Britain and the careers of such knights of the Round Table as Lancelot, Gareth, and Tristan. The book provides the fullest version of the legends of Arthur and his court ever written in English.

Scholars disagree on the identity of the author of *Le Morte Darthur.* Records from the 1400's show that several Englishmen named Thomas Malory lived at this time. A knight of Warwickshire, who was imprisoned for a se-

ries of crimes, is usually identified as the author.

Malory translated and adapted much of his work from earlier French and English writings about Arthur. He finished his work about 1470. William Caxton, the first English printer, published the first edition of the book in 1485. He made the title of Malory's last section, *Le Morte Darthur,* stand for the entire book. A manuscript copy of Malory's work was found at Winchester College in England in 1934. The most accurate and complete modern editions of the book are based on the Winchester manuscript. Malory's book has influenced the work of many artists and writers. Such writers include the English poets Edmund Spenser and Lord Tennyson. Edmund Reiss

Malpighi, *mahl PEE gee,* **Marcello,** *mahr CHEHL loh* (1628-1694), an Italian anatomist, physician, and botanist, became famous for his research on animal tissues and his mastery of the use of the microscope in his work. He made fundamental discoveries about human anatomy.

In 1659, Malpighi began to dissect the lungs of dogs and frogs. He examined the tissues under a microscope and discovered that lungs are made up of tiny air sacs, called *alveoli.* He also found that the veins connect to the arteries by *capillaries,* microscopic blood vessels.

Malpighi was the first person to observe and describe red blood cells, though he did not understand their significance. He described the tiny structures of the liver, spleen, and kidneys, as well as some of their functions. Later, he provided the first full accounts of the body structures of insects and of developing chick embryos. Other research by Malpighi advanced understanding of the structure of plants.

Malpighi was born on March 10, 1628, in Crevalcore, near Bologna. He studied medicine and philosophy at the University of Bologna. He became a professor of medicine at the universities of Pisa, Bologna, and Messina. He later served as physician to Pope Innocent XII. John Scarborough

Malpractice suit is a lawsuit in which a professional person is accused of injuring a patient or client through negligence or error. Most malpractice suits involve physicians. A smaller number involve lawyers.

The number of malpractice suits against doctors increased greatly in the United States beginning in the early 1970's. Most of these suits are filed against surgeons and other specialists who perform medical procedures that involve great risks to patients or that can have lifelong consequences. The amount of money awarded in successful malpractice suits also increased. Many such awards have greatly exceeded $1 million.

With the increased number of suits and the large amounts of money awarded, the cost of malpractice insurance for physicians soared. But some insurance companies dropped all malpractice coverage. The higher cost of malpractice insurance, like the rise in number of suits and in amounts awarded, contributed to sharp rises in the cost of medical care. Physicians passed the higher insurance cost on to patients by increasing their fees. Some physicians also began to order expensive laboratory tests and X rays as protection in case they were later sued. Some surgeons became hesitant to perform risky operations, and some older doctors retired.

Physicians and many state legislatures proposed various solutions to the problem. One proposal involved the creation of panels of doctors, lawyers, and other people to review malpractice cases before the suits go to court. Other approaches included laws that set limits on the amount of money awarded and on the fee of the trial lawyers. Some courts have ruled that such statutes are unconstitutional, and others have upheld them.

Malpractice suits against other professionals have also increased since the early 1970's. Many clients sued attorneys who lost a case. Most of these suits resulted from a technical mistake, such as failing to file a suit on time. Others involved lawyers who failed to complete legal work. Malpractice suits have also been brought against accountants and clergy. Troyen Brennan

Malraux, *mal ROH,* **André,** *ahn DRAY* (1901-1976), was a French author who combined intellectual achievement with political activity. He was born on Nov. 30, 1901, in Paris. From 1923 to 1927, he traveled in the Far East as a student of archaeology, Asian languages, and art. While there, Malraux became involved in local revolutionary struggles for freedom. In the 1930's, he participated in the struggles against Nazism in Germany and Fascism in Spain. In World War II, he fought with the French resistance forces against the Germans. Malraux served as France's first secretary of cultural affairs from 1959 to 1969.

Malraux's novels reflect his involvement in battles for freedom. However, his books are not autobiographical. Malraux's fiction explores humanity's devotion to ideals. He wanted art "to give men a consciousness of their own hidden greatness." His style is simple, concise, and fact filled. But it may burst into poetic imagery and suggests our solitude and everpresent sense of death. His best novels include *The Royal Way* (1930), *Man's Fate* (1933), *Days of Wrath* (1935), and *Man's Hope* (1937). Malraux also wrote *The Voices of Silence* (1951) and other important works on art that compare works of different periods and civilizations. Elaine D. Cancalon

Malt is a food product that results when barley and certain other grains are specially treated. In the United States and Canada, beer makers use 95 percent of the malt that is produced. It is also used in distilling, and as a source of flavor or aroma in a variety of baked goods, candies, cereals, and infant formulas.

In the malting process, manufacturers steep grain in cool water for 20 to 50 hours. They then spread the grain on large, ventilated floors and allow it to sprout and grow for 4 to 6 days. Temperature and moisture are carefully controlled. Next, large *kilns* (ovens) dry the grain for 2 or 3 days. After drying, the malt is cooled and the rootlets, which are used in animal feed, are removed from the sprouts. Finally, after cleaning, the malt is aged for 4 to 8 weeks before manufacturers use it.

During the malting process, certain chemical changes take place in the grain. Malting releases enzymes called *amylases.* These enzymes bring about the conversion of starch in the grain to sugars. Malting also produces enzymes called *hydrolases,* which are involved in breaking down proteins and nucleic acids. Robert D. Wych

Malta is an island country in the Mediterranean Sea, about 60 miles (97 kilometers) south of the island of Sicily. It consists of the inhabited islands of Malta, Gozo, and Comino, and the tiny, uninhabited islands of Cominotto and Filfla. It is one of the most densely populated countries in the world. Valletta, on the island of Malta, is the capital and chief port.

Terraces cut into the landscape for farming make much of the countryside look like giant steps. The balmy climate attracts many visitors. Tourists also come to Malta to view some of the world's finest examples of Baroque and Renaissance art and architecture.

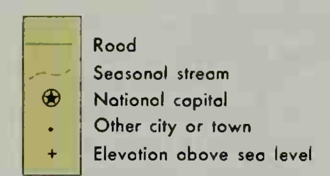
Malta was once a colony of the United Kingdom. In 1964, Malta became an independent country.

Government. Malta is a republic. The president is head of state and is appointed by parliament to a five-year term. The prime minister—usually the leader of the majority party in parliament—is the country's most powerful official. A Cabinet assists the prime minister in carrying out government operations. The 65 members of the House of Representatives are elected by the people to five-year terms.

People. Most of Malta's people speak a language called Maltese, a West Arabic dialect with some Italian words. Both English and Maltese are official languages. Maltese is used in the courts. The country has both Maltese and English newspapers. Roman Catholicism is the state religion of Malta.

All children must attend school, and lessons are taught in both English and Maltese. Malta has both public schools and Roman Catholic schools. By law, all schools must teach Roman Catholic religious doctrine. The University of Malta is in Msida, near Valletta.

Land. Malta covers a total area of 122 square miles (316 square kilometers). Malta island covers 95 square miles (246 square kilometers). Gozo covers 26 square miles (67 square kilometers). Comino covers about 1 square mile (3 square kilometers). Malta has limited supplies of fresh water. It relies heavily on *desalination plants* that turn seawater into fresh water.



Climate. Malta has a mild climate. Winters are moist and mild, and frost is unusual. Summers are hot and dry, but the heat is moderated by sea breezes. The country gets about 21 inches (53 centimeters) of rainfall a year. Northwest winds sometimes reach hurricane force in autumn and winter.

Economy. Tourism plays a major role in Malta's economy. Over a million tourists visit the country each year.

Facts in brief

Capital: Valletta.
Official languages: Maltese and English.
Area: 122 mi² (316 km²).
Population: *Estimated 2002 population*—394,000; density, 3,230 per mi² (1,247 per km²); distribution, 89 percent urban, 11 percent rural. *1985 census*—345,418.
Chief products: *Agriculture*—grapes, milk, onions, potatoes, tomatoes. *Manufacturing and processing*—beverages, processed food, shipbuilding and repair.
National anthem: "Innu Malti" ("Maltese Anthem").
Flag: A replica of the George Cross, a British medal awarded to Malta for bravery in World War II, appears on a white and red field. See **Flag** (picture: Flags of Europe).
Money: *Basic unit*—lira. One hundred cents equal one lira.

Malta

WORLD BOOK maps

Many of Malta's people work at the dockyards and in the shipbuilding industry. The one-time British naval dockyards are now used for commercial shipbuilding and repair.

Maltese farmers raise cauliflower, flowers for export, grapes, onions, potatoes, tomatoes, and wheat. Most crops are small because of the rocky soil. Malta must import most of its food. It has no minerals or natural resources, except salt and limestone.

Malta imports more goods than it exports. Its main trading partners are France, Germany, the United Kingdom, and the United States.

The country has a good road network and extensive local bus service. Ferry service links Malta with Gozo. Luqa has an international airport.

History. Malta is a region of great historical interest. Through the years, it has had much military importance because of its strategic location and natural harbors.

Remains of late Stone Age and Bronze Age people have been found in limestone caverns on the islands. Rough stone buildings from early ages have also been discovered in Malta. The Phoenicians colonized Malta in about 1000 B.C. Temples, tombs, and other relics of the Phoenicians still stand. Greek, Carthaginian, Roman, and Arab conquerors followed the Phoenicians into Malta. According to tradition, the Christian apostle Paul was shipwrecked near Malta about A.D. 60 and converted the inhabitants to Christianity.

Malta passed to the Norman kings of Sicily around 1090. About 1520, the Holy Roman Emperor Charles V

inherited the area when he received the crown of Spain. In 1530, Charles V gave Malta to the Knights Hospitallers. For this reason, the Knights are sometimes called the Knights of Malta. The Knights Hospitallers wore the Maltese cross as their badge (see Cross [picture]). They had fought against the Muslims since the time of the First Crusade in the 1090's. In 1565, the Ottoman Empire, based in what is now Turkey, laid siege to Malta with naval and military forces. Though heavily outnumbered, the Knights held out against the Ottomans for months and finally defeated them. The town of Valletta was named for Jean de la Vallette, the Grand Master who led the Knights against the Ottomans.

The French under Napoleon Bonaparte took Malta from the Knights Hospitallers in 1798. British forces drove out the French in 1800. The people of Malta offered control of the colony to the United Kingdom. British control was not completely recognized, however, until peace was made with France in 1815, after the Napoleonic Wars. The United Kingdom developed its Mediterranean military headquarters on Malta.

During World War I (1914-1918), Malta served as a strategic naval base for Allied forces. The United Kingdom granted Malta some self-government in 1921. However, the United Kingdom suspended Malta's constitution in 1930 because of a dispute between the state and Roman Catholic authorities. They disagreed about the role of the church in state affairs. The constitution was reestablished in 1932, then withdrawn a year later. This time the pro-Italian sympathies of the Maltese government led the United Kingdom to suspend the constitution. Full authority was returned to the governor in 1936.

During World War II (1939-1945), Malta controlled the vital sea lanes between Italy and Africa. The natural rocks and deep inlets of the colony concealed anchorages and submarine bases. Many underground passages provided bomb shelters. Fighter planes based on Malta defended convoys of ships. The colony suffered heavy bomb damage. In 1942, King George VI of the United Kingdom awarded the George Cross to Malta in recognition of the courage and endurance of the Maltese people during the war. In 1953, the North Atlantic Treaty Organization (NATO) established its Mediterranean military headquarters on Malta.

The constitution of 1947 gave the colony increased self-government. The Maltese Labour Party gained control of the assembly and proposed political integration with the United Kingdom. Voters approved a 1956 referendum on integration, but members of the Maltese Nationalist Party refused to vote in the referendum. This, combined with concerns over details of the agreement, brought the plans to an end.

The drive for independence gained strength in the late 1950's. A constitution approved in 1962 provided that the colony become a state with internal self-government. The new legislative assembly favored full independence. The United Kingdom agreed to grant full independence in May 1964. But disagreement among Malta's political factions delayed the action until September 1964.

Malta's political parties could not agree on whether to become a republic or a constitutional monarchy after independence. Some factions did not even want independence from the United Kingdom. But the Nationalist Party defeated the Labour Party on these measures, and Malta became an independent constitutional monarchy on Sept. 21, 1964. Giorgio Borg Oliver, leader of the Nationalist Party, became prime minister. In 1971, the Labour Party won a majority in parliament. Party leader Dom Mintoff became prime minister.

In 1974, Malta's parliament amended the constitution to change the form of government to a republic. Mintoff remained as prime minister. The Labour Party kept its majority in parliament in the 1976 and 1981 elections, and Mintoff continued to serve as prime minister until he resigned in 1984.

In 1979, an agreement between the United Kingdom and Malta that permitted the use of military facilities on Malta expired. The United Kingdom and NATO then withdrew their forces.

In 1987 elections, the Nationalist Party won a majority in parliament, and its leader, Eddie Fenech Adami, became prime minister. In 1992 elections, the Nationalists again won a majority. In 1996 elections, the Labour Party won the most votes, but elections in 1998 returned the Nationalists and Fenech Adami to power. John A. Davis

Malta fever. See **Brucellosis.**

Diana Rawson, Photo Researchers

Malta's capital, Valletta, borders the Mediterranean Sea. The city has been the capital of Malta since 1571. It is also the country's chief port.

Maltese was probably the world's first lap dog. It developed on the Mediterranean island of Malta more than 2,000 years ago. Ladies in Greek and Roman noble families were fond of these dogs. They carried them in the sleeves of their robes and waited on the dogs as though they were babies. The Maltese grew to be one of the gentlest of all toy dogs. It usually weighs from 4 to 6 pounds (1.8 to 2.7 kilograms). Its black eyes have dark rims that make the eyes look large. Its white coat falls from a part down its back, and may grow so long it trails on the ground. See also **Dog** (picture: Toy dogs).

Critically reviewed by the American Kennel Club

Malthus, *MAL thuhs,* **Thomas Robert** (1766-1834), was an English economist. He is best known for his *Essay on the Principle of Population* (1798). His main idea in this book is that population tends to increase more rapidly than food supplies. He believed that wars and disease would have to kill off the extra population, unless people limited the number of their children.

Malthus's *Essay* suggested to Charles Darwin the relationship between progress and natural selection. This was a basic idea in Darwin's theory of evolution (see **Darwin, Charles R.**). Malthus's prediction failed to come true in the 1800's. Improved methods of agriculture provided enough food for most people. But rapid population growth in the 1900's, especially in underdeveloped countries, led to renewed interest in Malthus's theories. Many conservationists warn that food production cannot keep pace with population indefinitely. But others disagree, claiming that food production technology continues to improve.

Malthus was born on Feb. 17, 1766, in Surrey. He decided to be a clergyman, and was graduated from Cambridge University. About 1796, he took a parish in Surrey. He became a professor of history and political economy in the college of the East India Company in 1805, and held this post until his death. M. Omar Rahman

Maltose, *MAWL tohs,* is the chemical term for malt sugar. The formation of maltose in the body is the first step in the digestion of starchy foods. The enzyme *ptyalin* in saliva changes starch into maltose. Other enzymes in the body split the maltose into glucose (see **Glucose**). Commercially, the enzyme *diastase* in malt changes starch into maltose. Fermentation changes maltose into alcohol. This is recovered by distillation. Maltose is used for sweetening some foods. See also **Brewing; Digestive system; Malt.** Kay Franzen Jamieson

Mamba, *MAHM buh* or *MAM buh,* is the name of three deadly snakes of central and southern Africa. Mambas are closely related to the cobras but do not have a hood (see **Cobra**). Mambas are slender and look somewhat like whips. They are usually about 6 to 8 feet (1.8 to 2.4 meters) long but may be as long as 14 feet (4.3 meters). Mambas glide rapidly in trees as well as on the ground. They produce a deadly poison. The black mamba is green when young and dark brown when adult. The green mamba is green throughout its life.

Albert F. Bennett

WORLD BOOK illustration by Richard Lewington, The Garden Studio

The mamba, a close relative of the cobra, is a poisonous snake that lives in central and southern Africa.

Scientific classification. The mambas belong to the family Elapidae. The scientific name for the black mamba is *Dendroaspis polylepis.* The green mamba is *D. angusticeps.*

Mamelukes, *MAM uh looks,* were a military group that ruled Egypt from about A.D. 1250 to 1517. They were originally Turkish, Mongol, and Circassian slaves first brought to Egypt in the late 1100's. The Mamelukes were trained as soldiers and rose to high army and government posts before they revolted and seized control of Egypt. See **Egypt** (History; picture). In time, they extended their rule to Palestine, Syria, and southern Asia Minor (now Turkey). The Ottoman Empire defeated the Mamelukes and conquered Egypt in 1517. But the Mamelukes quickly regained influence under the Ottomans. In 1811, Muhammad Ali, Egypt's Ottoman governor, ordered the massacre of the Mamelukes. A few escaped to Nubia to reorganize. But they could not defeat Ali's modern army and soon disappeared. Andrew C. Hess

Mamet, *MAM eht,* **David** (1947-), is a leading American playwright. In his major plays, Mamet uses forceful, realistic dialogue to create a world he sees as corrupt and morally decayed and ready for radical change. Mamet often focuses on how following an amoral business ethic reduces people to commodities and creates an emotional and spiritual wasteland.

Mamet first gained attention for two short plays, *Duck Variations* (1972) and *Sexual Perversity in Chicago* (1974). His first major full-length drama was *American Buffalo* (1977), a naturalistic study of three petty criminals. *Glengarry Glen Ross* (1984) is an exposé of greed and cynicism among real estate salesmen. The play won the 1984 Pulitzer Prize for drama. *Speed-the-Plow* (1988) is a satiric portrait of the movie industry in Hollywood. *Oleanna* (1992) examines charges of sexual harassment between a college professor and a graduate student. *The Cryptogram* (1995) deals with the psychological abuse of a child by the adults closest to him.

Mamet has written several successful screenplays, including *The Verdict* (1982), *The Untouchables* (1987), and *Things Change* (1988). He wrote and directed the motion pictures *Homicide* (1991), *State and Main* (2000), and *Heist* (2001). His nonfiction pieces were collected in *Writing in Restaurants* (1986) and *Some Freaks* (1990). He also wrote a novel, *The Village* (1994). Mamet was born on Nov. 30, 1947, in Chicago. Thomas P. Adler

The flying lemur of Southeast Asia glides from tree to tree by spreading the folds of skin that connect its neck, legs, and tail. The animal does not really fly, but it can travel nearly 100 yards (91 meters) through the air.

The zebra is a striped member of the horse family. No individual zebra's stripes are identical to those of another zebra. The kind of zebra shown here, Grevy's zebra, is an endangered species.

Among Alaskan fur seals, the males and females live together only during the summer mating season. The rest of the year, the males make their home in the Gulf of Alaska, while the females live as far south as the coast of California.

The star-nosed mole has 22 pink, fleshy "feelers" at the end of its snout. The mole uses its feelers to find the insects and worms it eats. These feelers can detect movement of the prey. Star-nosed moles live in damp or muddy soil in various parts of eastern North America.

Mammal

Mammal is an animal that feeds its young on the mother's milk. There are more than 4,500 *species* (kinds) of mammals, and they make up one of the classes of *vertebrates* (animals with backbones). Many mammals are among the most familiar of all animals. Cats and dogs are mammals. So are such farm animals as cattle, goats, hogs, and horses. Mammals also include such fascinating animals as anteaters, apes, giraffes, hippopotamuses, and kangaroos. And human beings, too, are mammals.

The contributors of this article are Robert M. Timm, Curator of Mammals and Professor of Systematics and Ecology at the University of Kansas Natural History Museum, and Barbara L. Clauson, Adjunct Curator of Mammals at the University of Kansas Natural History Museum.

Mammals live almost everywhere. Such mammals as monkeys and elephants dwell in tropical regions. Arctic foxes, polar bears, and many other mammals make their home in polar regions. Such mammals as camels and kangaroo rats live in deserts. Certain others, including seals and whales, swim in the oceans. One group of mammals, the bats, can fly.

The largest animal that has ever lived, the blue whale, is a mammal. It can measure more than 100 feet (30 meters) long and weigh more than 150 short tons (135 metric tons). The smallest mammal is the Kitti's hog-nosed

The sloth spends most of its life in the treetops. It moves slowly along the underside of branches, hanging upside down by its claws. Sloths live in Central and South American rain forests.

Amazon River dolphin

Ganges River dolphin

Dolphins are mammals that live in water. Most kinds of dolphins live in the ocean. However, the Amazon River dolphin and the Ganges River dolphin dwell in fresh water.

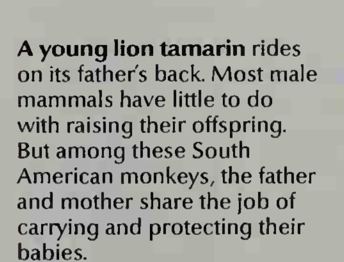
Interesting facts about mammals

Blue whale

WORLD BOOK illustration by Alex Ebel

The largest mammal—and the largest animal that has ever lived—is the blue whale. It measures up to 100 feet (30 meters) long when fully grown.

Kitti's hog-nosed bat



WORLD BOOK illustration by John Dawson

The Kitti's hog-nosed bat of Thailand is probably the smallest mammal. It is about the size of a bumble bee and weighs no more than a penny.

African rhinoceros

The rhinoceros has horns that look like closely packed hairs. Actually, they consist of many fibers of *keratin,* the horny substance that makes up the nails of people. African rhinos have two horns. Indian rhinos have one.

Lion tamarins

A young lion tamarin rides on its father's back. Most male mammals have little to do with raising their offspring. But among these South American monkeys, the father and mother share the job of carrying and protecting their babies.

Hyrax

The hyrax is a mammal that looks much like a large guinea pig. But scientists believe that its nearest relatives are actually elephants. Hyraxes, which are also known as conies, live in Africa and the Middle East.

WORLD BOOK illustrations by James Teason unless otherwise credited

bat of Thailand. It is about the size of a bumble bee and weighs only about $\frac{1}{14}$ ounce (2 grams).

Some mammals live a long time. Elephants, for example, live about 60 years, and some human beings reach the age of 100 years or more. On the other hand, many mice and shrews live less than a year.

Mammals differ from all or most other animals in five major ways. (1) Mammals nurse their babies—that is, they feed them on the mother's milk. No other animals do this. (2) Only mammals have true hair. All mammals have hair at some point in their life, though in certain whales it is present only before birth. Other living things, including bees and some plants, possess hairlike coverings on their bodies. But these coverings are not true hair. (3) Mammals are *warm-blooded*—that is, their body temperature remains about the same all the time, even though the temperature of their surroundings may change. Birds are also warm-blooded, but nearly all other animals are not. (4) Mammals have a larger, more well-developed brain than do other animals. Some mammals, such as chimpanzees, dolphins, and especially human beings, are highly intelligent. (5) Most mammals give their young more protection and training than do other animals. Other unusual characteristics of mammals include a four-chambered heart, a lower jaw with a single bone on each side, and an outer ear.

This article provides general information about mammals. Several hundred *World Book* articles give details on specific kinds of mammals. For a list of these articles, see the *Related articles* at the end of this article. In ad-

dition, the article **Animal** has much information on mammals, such as the tables *Names of animals and their young* and *Length of life of animals.*

The importance of mammals

How people use mammals. Since the earliest times, human beings have hunted other mammals. Prehistoric people ate the flesh of wild mammals, used their skins for clothing, and made tools and ornaments from their bones, teeth, horns, and hoofs.

More than 10,000 years ago, people learned they could *domesticate* (tame and raise) certain useful mammals. Hunters tamed wolves and from them bred dogs, the first domestic animals, to guard homes and track and bring down game. People later domesticated the wild ancestors of today's cattle, goats, hogs, and sheep. Since then, these mammals have provided meat, leather, and other products. Horses and oxen have long been used to carry people or their goods. Camels, elephants, goats, llamas, reindeer, and even dogs have also been used for transportation.

Some mammals, especially cats, dogs, hamsters, and rabbits, are popular pets. Certain mammals are used in scientific research. For example, new drugs are tested on domestic mice and rats and on dogs, guinea pigs, monkeys, and rabbits.

Although domestic mammals provide many products, people still hunt wild mammals. They hunt such mammals as antelopes, deer, rabbits, and squirrels for their flesh or hides. Whales are killed for their meat and oil, and seals for their skins. Beavers, muskrats, otters, and other wild mammals that have thick coats are trapped for their fur. Elephants, hippopotamuses, and walruses are killed for their tusks, which consist of ivory. Rhinoceroses are killed for their horns.

Wild mammals are also a source of enjoyment. Many people travel to national parks to delight in viewing bears, deer, moose, and other mammals in their natural environments. Other people visit zoos, where they can see interesting mammals from many countries. Even in the largest cities, people can still find some wild mammals, such as the gray squirrel and the chipmunk.

Mammals in the balance of nature. Mammals are important not only to people but also to the whole system of life on the earth. Many mammals help plants grow. For example, animals that eat plants leave seeds in their *droppings* (body wastes). Many of these seeds sprout into plants. Similarly, many of the nuts that squirrels bury for a food supply grow into trees. Gophers, prairie dogs, and other burrowing mammals dig up the soil. This activity mixes the soil with air, water, and decaying leaves, which promotes the growth of plants.

Flesh-eating mammals also help maintain the balance of nature by feeding on plant-eating animals. If such flesh-eaters as wolves, mongooses, and weasels did not control the number of plant-eaters, certain species of plants in an area could be drastically reduced or even wiped out. Other mammals help keep the insect population under control. For example, aardvarks, giant anteaters, and pangolins eat millions of ants and termites at each meal. Every night, bats eat great numbers of insects. *Scavenger* mammals, such as coyotes, hyenas, and jackals, clean up the remains of large animals that have been killed or that died naturally.

Even the wastes and dead bodies of mammals are important to the balance of nature. Mammal droppings are a valuable fertilizer. The bones of dead mammals break down into chemicals that are needed by animals and plants. Rodents often chew on mammal bones and antlers that deer have shed because these remains are important sources of calcium and other minerals. For more information, see **Balance of nature.**

The bodies of mammals

Mammals have many ways of life, and each species has a body adapted to its particular way of life. However, all mammals share some basic body characteristics. These characteristics include certain features of their (1) skin and hair, (2) skeleton, and (3) internal organ systems.

Skin and hair cover the body of mammals. Skin consists of an inner layer, the *dermis,* and an outer layer, the *epidermis.* The dermis contains the arteries and veins that supply the skin with blood. The epidermis, which has no blood vessels, protects the dermis. It also produces special skin structures, including hair, horns, claws, nails, and hoofs.

The skin of mammals has a rich supply of glands. *Mammary glands* produce the milk that female mammals use to nurse their young. *Sebaceous glands* give off oil that lubricates the hair and skin. *Sweat glands* eliminate small amounts of liquid wastes, but their main purpose is to help mammals cool off. As sweat evaporates from the skin, it cools the surface. Many mammals, such as dogs and skunks, also have *scent glands.* Dogs use their scent glands for communication and identification. Skunks spray a bad-smelling liquid from their scent glands as a means of self-defense.

Many mammals have two types of hairs. The *underhair* consists of soft, fine hairs that form a thick, warm coat. The outer *guard hair* consists of longer, slightly stiffened hairs that give shape to a mammal's coat and protect the underhair. Many mammals have long, stiff hairs about the mouth or other parts of the head. These hairs, called *vibrissae* or *tactile hairs,* serve as highly sensitive touch organs. The whiskers of cats and mice are examples of such hairs.

Hair serves many purposes. The hair color of many mammals blends with the animals' surroundings and so helps them hide from their enemies or prey. Some mammals have specialized guard hairs, such as the quills on a porcupine, that provide protection against enemies. But the main purpose of hair is to keep the animal warm. Dolphins and whales, which lack body hair, have a thick layer of fat that provides warmth. Other mammals with little hair, such as elephants and rhinoceroses, live in warm climates. See **Skin; Hair.**

Skeleton of mammals provides a framework for the body and protects vital organs. In addition, the muscles that enable a mammal to move are attached to the skeleton. The skeleton of all adult mammals—whether blue whales or shrews—consists of more than 200 bones. Some of these bones are *fused* (united) and so form a single structure. The skeleton has two main parts: (1) the axial skeleton and (2) the appendicular skeleton.

The axial skeleton consists of three regions. These regions are the skull, the vertebral column, and the thoracic basket.

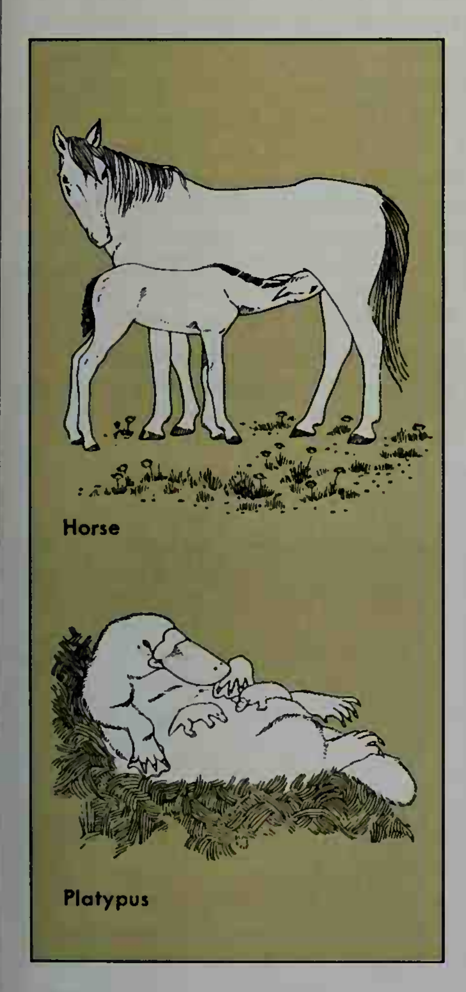
The skull houses the brain in a bony box called the

cranium. The skull also includes the jaws and teeth and areas for the organs of hearing, sight, and smell. Some mammals have bony growths from the skull, such as the antlers on deer.

The vertebral column, or spine, consists of five kinds of *vertebrae* (spinal bones): (1) *cervical,* in the neck; (2) *thoracic,* in the chest; (3) *lumbar,* in the lower back; (4) *sacral,* in the hip; and (5) *caudal,* in the tail. All mammals, except manatees and sloths, have seven cervical vertebrae. The number of each of the other kinds of vertebrae varies with the species of mammal.

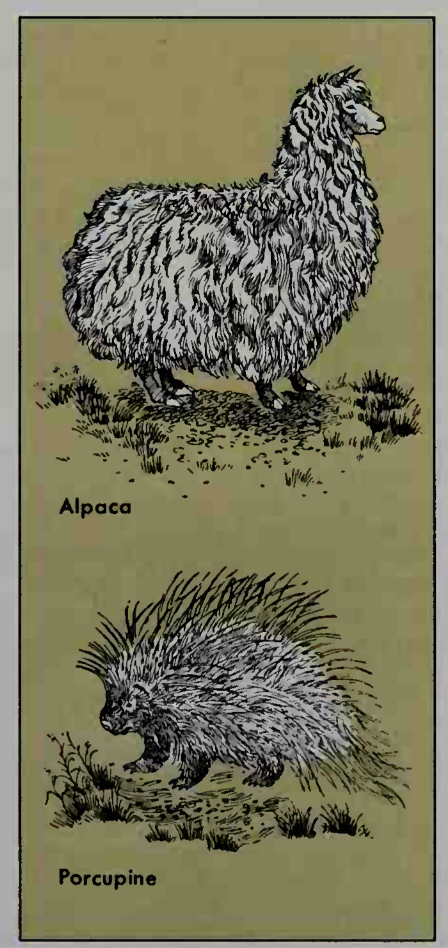
The thoracic basket is made up of the ribs, which are attached to the thoracic vertebrae. Most of the ribs also are joined to the breastbone. The thoracic basket forms a bony cage that protects the heart, lungs, and other vital organs.

The appendicular skeleton is made up of the limbs and their supports. The forelimbs are attached to the axial skeleton by the shoulder girdle, which consists of a broad shoulder blade and, in most species, a narrow collarbone. The hindlimbs are attached to the sacral vertebrae by a hip girdle consisting of three bones. In many mammals, the three bones of the hip girdle are fused to one another and to the sacral vertebrae.



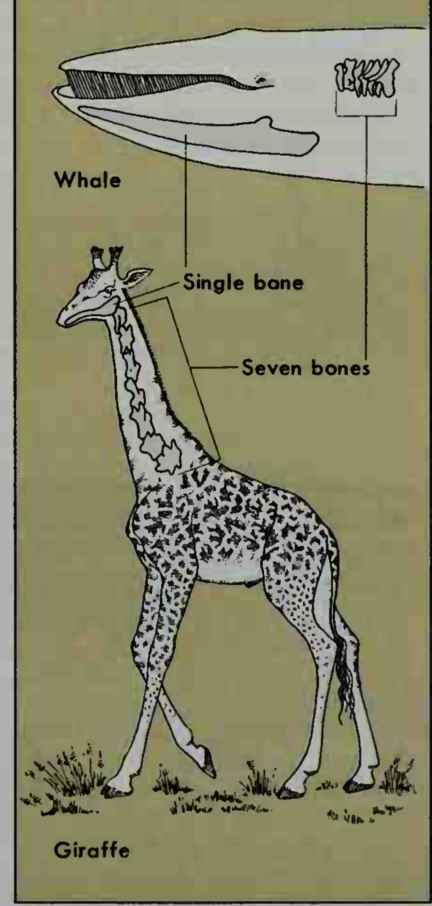
A single bone forms the upper portion of each limb. In most mammals, the lower part of each limb has two bones. These bones are fused in some mammals. The wrist, palm, ankle, and sole consist of several small bones. The number of these depends on how many fingers or toes the mammal has. See **Skeleton**.

Internal organ systems are groups of organs that serve a particular function. The major systems of mammals include (1) the circulatory system, (2) the digestive system, (3) the nervous system, and (4) the respiratory system.



The circulatory system consists of the heart and blood vessels. Mammals have an extremely efficient four-chambered heart, which pumps blood to all parts of the body. The blood carries food and oxygen to the body tissues, where they are burned to release energy. The red blood cells of mammals can carry more oxygen than can the cells of all other animals except birds. The circulatory system's high efficiency is associated with warm-bloodedness. Mammals must burn large amounts of food to maintain a high body temperature. See **Blood; Circulatory system; Heart** (Birds and mammals).

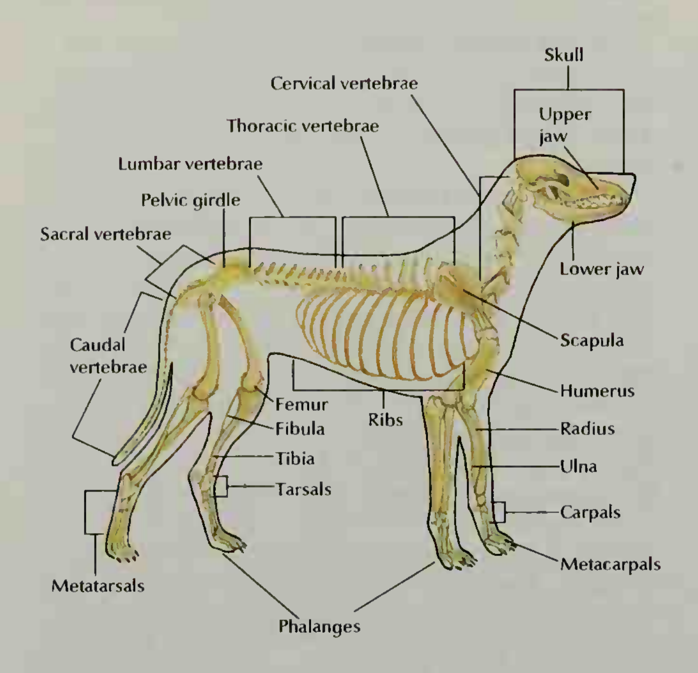
The digestive system absorbs nourishing substances from food. It consists basically of a long tube that is formed by the mouth, the esophagus, the stomach, and the intestines. The digestive system of mammals varies according to the kind of food an animal eats. Mammals that eat flesh, which is easy to digest, have a fairly simple

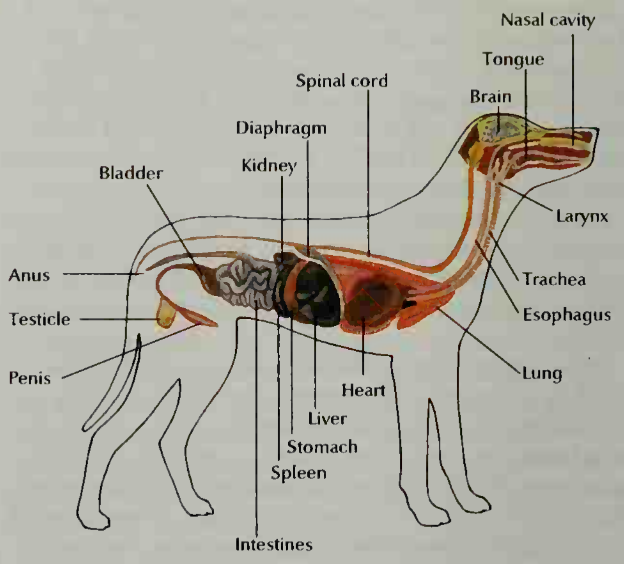


Some major characteristics of mammals

Mammals nurse their young. A colt, like most baby mammals, sucks milk from his mother's nipples. Baby platypuses lap milk from their mother's abdomen.

Mammals have hair. In the alpaca and most other mammals, a thick coat of hair provides warmth. The porcupine's quills are special hairs used for self-defense.





WORLD BOOK illustrations by Jean Helmer

Mammals have similar skeletons. Only one bone forms each side of the lower jaw in mammals. Almost all mammals have seven bones in the neck.

The anatomy of a mammal Although mammals differ greatly in size and shape, they all share a number of physical characteristics. These characteristics include the same basic skeletal and internal organ systems. The diagrams below show the skeleton and internal organs of a male dog.

WORLD BOOK diagrams by Jean Helmer

stomach and short intestines. Most mammals that eat plants, however, have a complicated stomach and long intestines. For example, cows and sheep have a four-chambered stomach. Each chamber helps break down the coarse grasses that the animals eat. See **Digestive system; Ruminant.**

The nervous system regulates most body activities. It consists mainly of the brain and spinal cord and their associated nerves. Most kinds of mammals have a larger brain than do other animals of similar size. In addition, mammalian brains have an extremely well-developed *cerebral cortex.* This part of the brain serves as the center for learning and gives mammals superior intelligence. See **Brain; Nervous system.**

The respiratory system enables mammals to breathe. It is made up of two lungs and various tubes that lead to the nostrils. A muscular sheet called the *diaphragm* divides the chest cavity from the abdominal cavity and aids in breathing. Only mammals have a muscular diaphragm. In most mammals, the nostrils are at the end of the snout or nose. Dolphins and whales have their nostrils, called *blowholes,* at the top of the head. Dolphins and some whales have one nostril. Other whales have two. See **Lung; Respiration.**

Other organ systems of mammals include the endocrine, excretory, and reproductive systems. The endocrine system consists of glands that produce *hormones,* substances which help regulate body functions. The excretory system eliminates wastes from the body by means of the kidneys. For information on these two systems, see the articles **Hormone** and **Kidney.** For a discussion of the reproductive system, see the section of this article titled *How mammals reproduce.*

The senses and intelligence of mammals

Senses. Mammals rely on various senses to inform them of happenings in their environment. The major senses of mammals are (1) smell, (2) taste, (3) hearing, (4) sight, and (5) touch. However, the senses are not equally developed in each species of mammal. In fact, some species do not have all the senses.

Smell is the most important sense among the majority of mammals. Most species have large nasal cavities lined with nerves that are sensitive to odors. These animals rely heavily on smell to find food and to detect the presence of enemies. In many species, the members communicate with one another through the odors produced by various skin glands and body wastes. For example, a dog urinates on trees and other objects to tell other dogs it has been there. A few species of mammals, especially human beings, apes, and monkeys, have a poorly developed sense of smell. Dolphins and whales seem to lack the sense entirely. See **Smell.**

Taste helps mammals identify foods and so decide what foods to eat. This sense is located mainly in *taste buds* on the tongue. However, much of the sense of taste is strongly affected by the odor of food. See **Taste.**

Hearing is well developed in most mammals. Most species have an outer ear, which collects sound waves and channels them into the middle and inner ear. Only mammals have an outer ear. See the *World Book* article **Ear** for a description of the human ear, a typical mammalian ear.

Some mammals use their sense of hearing to find food and avoid obstacles in the dark. Bats, for example, produce short, high-pitched sounds that bounce off surrounding objects. Bats can use these sounds and their echoes to navigate and even to detect tiny flying insects. Dolphins and whales also use this system, called *echolocation,* to navigate, find food, and avoid objects underwater. However, most of the sounds they make are pitched much lower than are the sounds of bats. Other echolocating mammals include shrews and some seals.

Sight is the most important sense among the *higher*

primates (apes, monkeys, and people). The structure and function of the eye is similar in all mammals. However, the eyes of the higher primates have more *cones* than do those of most other mammals. These structures give apes, monkeys, and people sharp daytime vision and the ability to tell colors apart. A few other mammals that are active during the day have some color vision, but most mammals are color-blind. Many species of mammals that are active at night have large eyes with a reflector at the rear. This reflector, called the *tapetum lucidum,* helps the animal see in the dark. It produces the *eye-shine* a person sees when light strikes the eyes of a cat or a deer at night. See Eye.

Touch. Most mammals have a good sense of touch. *Tactile nerves*—that is, nerves that respond to touch—are found all over a mammal's body. But some areas have an especially large number of these nerves and are extremely sensitive to touch. The whiskers of such mammals as cats, dogs, and mice have many tactile nerves at their base. These whiskers help the animals feel their way in the dark. Moles and pocket gophers have a highly sensitive tail, which aids them when backing up in their dark, narrow tunnels. Primates' fingers have many tactile nerves, as do the paws of raccoons.

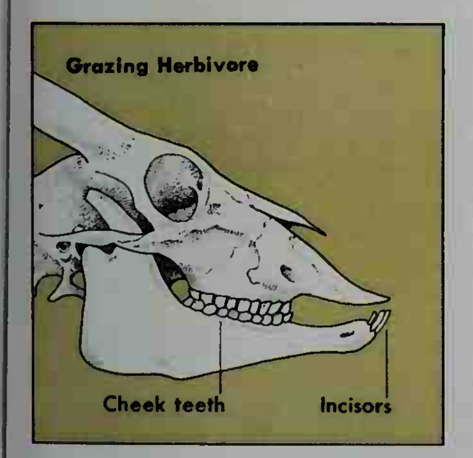
Intelligence is related to the ability to learn. Through learning, an animal stores information in its memory and then later uses this information to act in appropriate ways. Mammals, with their highly developed cerebral cortex, can learn more than other kinds of animals.

Intelligence is difficult to measure, even in human beings. The size of the surface area of the brain, especially of the cerebral cortex, generally indicates an animal's learning ability. In the more intelligent mammals, such as chimpanzees and dolphins, the cerebral cortex is fairly large and has many folds, which further increase its surface area. Human beings have the most highly developed cerebral cortex.

What mammals eat

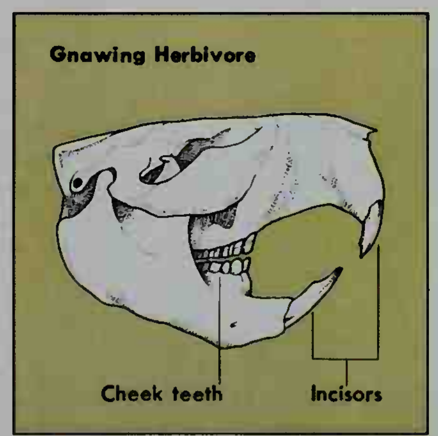
Most mammals are *herbivorous*—that is, they eat plants. Plant food is generally tough and so tends to wear teeth down. Herbivorous mammals have special teeth that help counteract such wear. Many plant-eating mammals, including cattle, elephants, and horses, have high-crowned teeth that wear down slowly. The *incisors* (front teeth) of such mammals as rodents and rabbits grow continuously to keep up with the wear caused by chewing.

Some mammals are *carnivorous.* They eat animal flesh. Many of them are speedy hunters that catch, hold, and pierce their prey with long, pointed *canine teeth.* Such mammals, which include leopards, lions, and wolves, do not thoroughly chew their food. They swallow chunks of it whole. Dolphins, seals, and other fish-eating mammals also use their teeth to grasp prey, which they swallow whole. Some carnivorous mammals commonly feed on the remains of dead animals, instead of hunting and killing fresh prey. Hyenas are especially adapted to such a diet and have extremely powerful jaws that can crush even large bones.



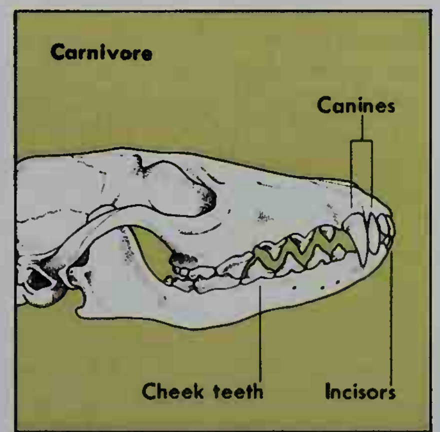
Various mammals eat insects. Many of these *insectivorous* mammals, such as bats, moles, and shrews, have teeth that can crush and slice off the hard outer parts of insects. This action exposes the softer flesh and juices, which the mammals feed on. Other insect-eaters, such as aardvarks, anteaters, echidnas, numbats, and pangolins, have weak teeth or none at all. These mammals eat ants and termites, which they lick up with their long, sticky tongues and swallow without chewing.

Some mammals eat both plants and animals. These *omnivorous* mammals have teeth that can grind up plants and tear off flesh. They include bears, hogs, opossums, raccoons, and human beings. Some omnivorous mammals change their diet with the seasons. For example, spotted skunks feed mostly on fruits, seeds, and insects in summer. In winter, they eat mainly mice and rats.



How mammals move

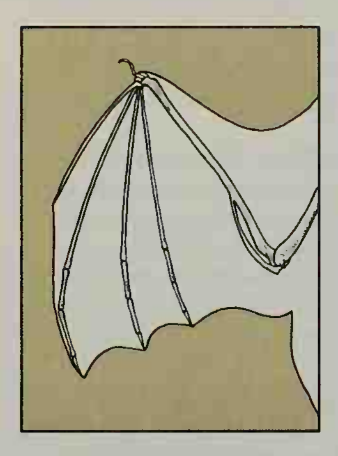
On land. Most mammals live on the ground. The majority of these *terrestrial* animals move about on four legs. They walk by lifting one foot at a time—first one



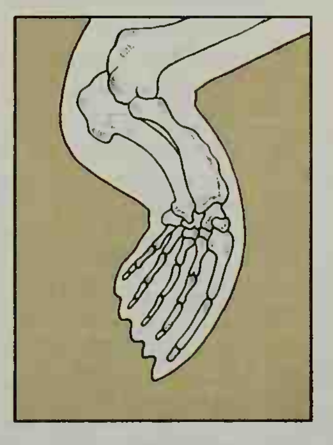
The teeth of mammals Mammals have three basic types of teeth: (1) *incisors* (front teeth), (2) *canines* (side teeth), and (3) *premolars* and *molars* (cheek teeth). The number and shape of these teeth vary according to diet.

Sheep teeth. A sheep snips off grass by pressing its lower incisors against a pad on its upper jaw. It uses the cheek teeth for grinding and has no canine teeth.

Beaver teeth. A beaver uses its huge incisors to gnaw the bark off plants. Like sheep, beavers use the cheek teeth for grinding and have no canine teeth.

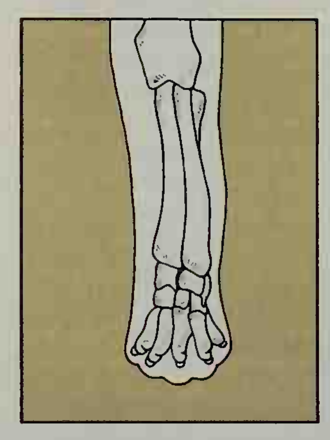


WORLD BOOK illustrations by Jean Helmer

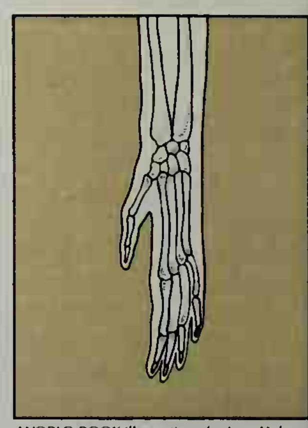


Red fox teeth. A red fox has small incisors but large, pointed canine teeth, which it uses to stab and hold prey. The cheek teeth are for cutting and crushing.

How the skeleton is adapted for movement



Although all mammals have a basic skeleton in common, it is adapted in each species to suit the particular way the animals move. These illustrations show various adaptations of the forelimb.



A bat's forelimb is adapted for flying. The bones of the hand and forearm provide the framework of the bat's wing.

A walrus's forelimb forms a paddlelike flipper. This mammal uses its forelimbs for swimming.

An elephant's forelimb provides a sturdy, pillarlike support to carry the enormous body over the ground.

WORLD BOOK illustrations by Jean Helmer

A gibbon's forelimb is adapted for swinging through trees. The animal has powerful arms and flexible fingers.

forefoot, then the opposite hindfoot, next the other forefoot, and then the opposite hindfoot. At faster speeds, most four-legged mammals *trot,* lifting one forefoot and the opposite hindfoot at the same time. A few species, including camels and giraffes, pace rather than trot. *Pacing* involves lifting both feet on one side of the body at the same time. At their fastest speed, most terrestrial mammals *gallop.* While galloping, the animal usually has only one foot on the ground at a time. At some point during the gallop, all four feet are in the air.

Jerboas, kangaroos, and kangaroo rats are terrestrial mammals that move by hopping. These animals have powerful hind legs. They also have a long tail that is used for balance.

In trees. Many mammals that live in forested areas spend most of their time in the trees. These *arboreal* animals have a number of special body features that help them move through the trees. Monkeys, for example, can use their hands and feet to grasp tree branches. Many monkeys of Central and South America also have a *prehensile* (grasping) tail, which they can wrap around branches for support. Other arboreal mammals with a prehensile tail include kinkajous, opossums, and phalangers. Some species of anteaters, pangolins, and Central and South American porcupines also have such a tail. Squirrels and tree shrews have sharp, curved claws that aid them in climbing trees. The claws of tree sloths are so long and curved that the animals cannot walk erect on the ground. These mammals spend most of their life hanging upside down from branches.

In water. Dolphins, porpoises, manatees, and whales are mammals that live their entire life in water. They have a streamlined body and a powerful tail, which they move up and down to propel themselves through the water. Their forelimbs are paddlelike flippers, used for balance and steering. They have no hindlimbs.

Many other mammals spend much, but not all, of their time in water. Some of these animals, such as capybaras, hippopotamuses, and walruses, swim by moving their forelimbs and their hindlimbs. Other species use mainly their forelimbs. Such swimmers include platypuses, polar bears, and fur seals and sea lions. Still other mammals use only their hindlimbs to swim. These animals include beavers and hair seals.

In the air. Bats are the only mammals that can fly. Their wings consist of thin skin stretched over the bones of the forelimbs. Bats fly by beating their wings forward and downward, then upward and backward.

The so-called flying lemurs, flying phalangers, and flying squirrels cannot actually fly. These mammals have a fold of skin between the forelimb and hindlimb on each side of the body. Instead of flapping these "wings," the animals stretch them out and glide from tree to tree.

Underground. Pocket gophers, moles, and certain other mammals spend almost all their life underground. Most of these *fossorial* mammals have strong claws and powerful forelimbs. Many of them have poor vision, and some are blind. The forelimbs of moles are turned so that the broad palms face out and backward. Strong chest muscles attached to the forelimbs enable moles to "swim" through the soil, much as a person swims when doing the breaststroke.

How mammals reproduce

All mammals reproduce sexually. In sexual reproduction, a *sperm* (male sex cell) unites with an *egg* (female sex cell) in a process called *fertilization.* The fertilized egg develops into a new individual. In all species of mammals, the eggs are fertilized inside the female's body. Male mammals have a special organ, the penis, which releases sperm into the female during *copulation* (sexual intercourse).

Mating occurs among most mammals only when the female is in *estrus,* also called *heat.* At this time, the female is sexually receptive and will permit copulation. See Estrous cycle.

The time of the estrous period varies with different species. Among many mammals, especially those that live where the climate is constant the year around, the females may come into heat at any time. Such *polyestrous* (many-estrous) mammals include elephants and giraffes. Among species that live in regions with distinct seasons, all the females may come into heat at a particular time of year. This *breeding season,* also called the

rutting season, is so timed that the offspring will be born when conditions are best for their survival. Some seasonal breeders have one heat period a year. Such *monestrous* (one-estrous) species include certain bats, bears, and deer. Other species, such as cottontail rabbits, have several heat periods during their breeding season. These mammals are *seasonally polyestrous.*

Most smaller mammals are *promiscuous* in their mating behavior. No lasting bond forms between the mates. They remain together only long enough to copulate. Some other species are *polygamous.* The males of such species, which include American elks and fur seals, gather a *harem* (group of females) just before and during the mating season. The male tries to mate with each member of his harem. The association between the male and his harem ends after the breeding season. Among many kinds of mammals, the males and females remain together for some time after mating. However, only a few species of mammals seem to take one mate for life. Zoologists believe that such *monogamous* species include beavers, wolves, and an antelope called a dik-dik.

Reproduction. Mammals can be divided into three groups according to the way in which new individuals develop from the fertilized eggs. These groups are (1) placentals, (2) marsupials, and (3) monotremes.

Placentals give birth to fairly well-developed off-

How mammals reproduce

All mammals reproduce sexually. A new individual begins to form after a *sperm* (male sex cell) unites with an *egg* (female sex cell). This union is called *fertilization.* Mammals can be divided into three groups according to the way in which the fertilized egg develops into a new individual. These groups are (1) placentals, (2) marsupials, and (3) monotremes.

Norman Myers, Bruce Coleman Inc.

Placentals give birth to fairly well-developed offspring, such as the newborn zebra shown above. A young placental mammal develops inside its mother, receiving nourishment from her through an organ called the *placenta.* Placentals make up the vast majority of mammals.

Leonard Lee Rue III, Bruce Coleman Inc.

Marsupials give birth to poorly developed young, such as these baby opossums. The young complete their development attached to the mother's nipples.

Warren Garst, Tom Stack & Assoc.

WORLD BOOK diagram by Jean Helmer

Monotremes, such as the platypus, *left,* lay eggs rather than bear their young alive. The female platypus digs a long tunnel in the bank of a stream, *right.* There she lays one to three eggs that have a leathery shell. The only other monotremes are the echidnas, or spiny anteaters. Platypuses and echidnas live in Australia and on nearby islands.

George Schaller, Bruce Coleman Inc.

A lion cub sucks nourishing milk from its mother's nipple. All baby mammals feed on mother's milk. In many species, the young continue to nurse long after they can eat solid foods.

Joe Branney, Tom Stack & Assoc.

A mother brown bear shows her cubs how to catch fish. Many young mammals learn how to obtain food by watching and imitating the behavior of their parents and other adults.

H Albrecht, Bruce Coleman Inc.

Young African hunting dogs romp together in a make-believe fight. This kind of play serves as an important learning experience. It helps develop the skills needed for hunting.

spring. The vast majority of mammals are placentals. After fertilization occurs, a placental mammal begins to develop in the *uterus,* a hollow organ in the mother's abdomen. Another organ, called the *placenta,* attaches the developing mammal, called an *embryo,* to the uterus wall. The embryo receives nourishment from the mother through the placenta.

The time during which the unborn young develops in the uterus is called the *gestation period.* Among placental mammals, the gestation period ranges from about 16 days in golden hamsters to about 650 days in elephants. Most species with a short gestation period give birth to young that are generally helpless and may be blind and hairless. Most species with a long gestation period bear young that are alert soon after birth. The newborns may also be fully haired, and some can even walk or run almost immediately.

Marsupials give birth to tiny, poorly developed offspring. Immediately after birth, the young attach themselves to the mother's nipples. The babies remain attached until they develop more completely. The nipples of most female marsupials are in a pouch, called the *marsupium,* on the stomach. Marsupials are often known as *pouched mammals.* However, not all female marsupials have a pouch. Certain kinds of opossums, for example, lack this feature.

There are about 270 species of marsupials. About two-thirds of them live in Australia and on nearby islands. Australian marsupials include kangaroos, koala bears, and wombats. About 70 kinds of opossums, which are marsupials, live in Central and South America. One species lives in the United States and southern Canada.

Monotremes, unlike all other kinds of mammals, do not give birth to live young. Instead, they lay eggs that have a leathery shell. After an incubation period, the eggs hatch. The only monotremes are the echidnas and the platypus. They live in Australia, New Guinea, and Tasmania.

Care of the young. All baby mammals feed on milk from their mother's mammary glands. Baby placentals and marsupials suck the milk from the mother's nipples. Female monotremes do not have nipples. The milk is released through pores on the mother's abdomen, and the young lap it up. The nursing period lasts only a few weeks in mice, hares, and many other species. But among some mammals, such as elephants and rhinoceroses, the young may nurse for several years before they are *weaned*—that is, taken off the mother's milk. In most species, the young can eat solid food long before they are weaned.

Young mammals must learn many of the skills they need to survive. Much of this learning occurs during the nursing period, when the young are taught how to obtain food and how to avoid dangers. Among most kinds of mammals, the mother alone raises the young. However, the males of some species help care for their offspring. For example, male mice of certain species aid in nest building. Male coyotes and African hunting dogs bring back food for the mother and puppies. Male lions help protect the mother and cubs from attacks by hyenas and other lions.

Among many smaller mammals, such as mice and shrews, the young leave the parental nest or den as soon as they are weaned. But among cheetahs, ele-

phants, wolves, and many other species, the young stay with their parents long after the nursing period ends.

Ways of life

Group life. Many mammals live in *social groups* of several individuals. The simplest social group consists of an adult male and female and their offspring. Beavers and certain species of monkeys form such family groups. A larger social group, such as a wolf pack, may have a number of adult and young animals of both sexes. Zebra herds, which consist of an adult male and several females and their young, make up another kind of social group.

Among many social species, the group members are ranked according to a *dominance hierarchy.* The *dominant* (controlling) members of the group get first choice of food and mates. They may establish their dominance at first by winning fights. Thereafter, they keep their position mostly by threats. See **Dominance**.

Group life offers several advantages. Killer whales, lions, wolves, and other *predators* (hunters) that live in groups cooperate in surrounding and bringing down prey. However, prey species can also profit from group life. If one white-tailed deer senses danger, for example, it can warn the entire herd by flashing the white underside of its tail. Among some prey species, such as baboons and musk oxen, the group assembles into a defensive formation for protection against predators.

Some mammals spend most of their life alone. Such *solitary* mammals include leopards, tigers, and most other cats except lions. However, even solitary mammals spend some time with members of their species. For example, adult males and females get together to mate, and a mother remains with her young at least until they are weaned.

Solitary mammals have several advantages over social species. They do not have to share available food and shelter. In addition, a solitary predator can hunt its prey more silently than can a group. Among prey species, a solitary animal attracts less attention than a group does, and it can hide more easily.

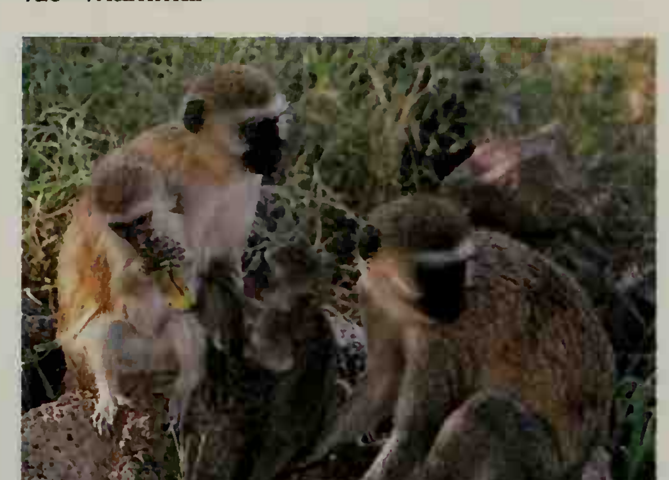
Territoriality is a form of behavior in which an animal or group of animals claims and defends a particular area. Other members of the species are kept out of the territory. Many species of mammals establish territories only during the breeding season. For example, a male fur seal claims a territory before mating. He drives all other males from his territory, while he tries to herd as many females as possible into the area. Other mammals, such as gibbons and howler monkeys, claim a territory to help ensure the group of an adequate food supply.

Mammals mark the boundaries of their territories in various ways. For example, hyenas leave solid body wastes and scents produced by special glands to indicate their territorial borders. Wolf packs mark their territories with urine. Such markers serve as "No Trespassing" signs to other members of the species.

Mammals usually defend their territories by threats rather than by actually fighting. A group of howler monkeys, for instance, keeps other howlers out of its territory by shouting at them.

Many mammals are not territorial. But most species, including those that do not claim a territory, have a *home range.* A mammal wanders over its home range during the daily activities of feeding, drinking, and seeking shelter. Unlike a territory, a home range is not defended against members of the same species. See **Territoriality**.

Migration. Many kinds of mammals make seasonal migrations to obtain a better food supply, to avoid harsh weather, or to do both. For example, various species of North American bats migrate southward each autumn because the insects that they feed on become scarce during the cold northern winter. Wildebeests and zebras in central Africa migrate in search of green grass during the yearly dry season. The American elk of Canada and the western United States spends the summer on high mountain slopes. In winter, it lives in the valleys below, where the snow is not as deep.



Some mammals migrate to an area to give birth or to mate. Every fall, for example, gray whales swim from their Arctic feeding waters to the warmer seas off the northwest coast of Mexico. These waters provide little or no food for the whales. The animals make the journey to give birth because newborn whales could not survive in the cold Arctic waters. See **Migration**.

Hibernation. Some kinds of mammals hibernate to avoid winter food shortages. During hibernation, an animal goes into *torpor,* a type of sleep from which it cannot be awakened quickly. The body temperature of a hibernating mammal is lower than normal. In fact, the temperature of most hibernators drops to nearly that of the surrounding air. The heartbeat and breathing slow down greatly. A hibernating mammal does not eat. It lives off the fat in its body. Some hibernating mammals pass in and out of torpor all winter.

Rod Allin, Bruce Coleman Inc.

Barren ground caribou are *social mammals*—that is, they live in groups. Caribou herds may include hundreds of members. The herds spend the summer in the Arctic tundra. As autumn approaches, they migrate south to evergreen forests, where they can get food during the winter.

R. T. W. from Carl E. Östman

Vervets, like all other species of monkeys, are social mammals. Vervets generally form bands of no more than 20 members. These monkeys are common throughout much of Africa.

K. W. Fink, Bruce Coleman Inc.

A male sea lion, *center,* claims a territory during the mating season. He keeps all other males out of his territory but tries to gather as many females as possible into the area.

Mammals that hibernate include many kinds of bats; echidnas; and chipmunks, woodchucks, and some other rodents. Most of these animals become extremely fat before they go into hibernation. They usually spend the winter in a den or some other protected place where the temperature is not likely to fall below freezing.

Some bears also enter into a sleeplike state during much of the winter. Many scientists believe that a bear's winter sleep can be classified as hibernation. However, many other scientists do not consider bears to be true hibernators because their body temperature falls only slightly during winter sleep.

A few kinds of mammals *estivate*—that is, they become inactive during the hottest, driest part of the summer. Estivation is most common in certain kinds of bats, rodents, and other small mammals. See **Estivation; Hibernation.**

Methods of attack and defense. Mammals that hunt rely mainly on their sharp teeth to catch and kill prey. Most of these predators also have sharp claws, which they use to grab and hold their victims. Solitary predators generally stalk their prey by slinking and hiding, and many of these hunters have coats that blend with their surroundings. After a predator has sneaked up on its prey, it makes a final dash at high speed to catch the animal before it can escape. Group hunters, such as African hunting dogs and wolves, usually take turns in the chase until they have worn the prey out.

Most mammals try to escape predators by fleeing. Many hoofed mammals, such as deer and impalas, can run swiftly for long distances. Ground squirrels, prairie dogs, and many other small mammals rush into a burrow or other hiding place. On the other hand, fawns and rabbits sometimes escape hunters by remaining absolutely still. This defense works because many predators are "sight hunters" and are attracted mainly by movement. The American opossum takes this defense one step further. It "plays dead" by going completely limp. Many predators lose interest in the apparently dead animal.

Some mammals have special features that help protect them from enemies. The bony shell of armadillos and the scales of pangolins serve as protection against sharp-clawed predators. The thick skin of elephants and rhinoceroses serves the same purpose. Echidnas, hedgehogs, and porcupines have sharp, stiff quills that stop most attackers. Skunks and their relatives spray a foul-smelling liquid when threatened. An animal that has been sprayed by a skunk will probably not want to threaten it again. The skunk's bold black-and-white markings make it easy for predators to remember to avoid the animal. Most prey species, however, have protective coloration that blends with their surroundings. The coat of some species changes seasonally to match the color of the terrain. For example, the coats of Arctic hares and Arctic foxes are brownish in summer. In winter, the coats turn white and so help hide the animals against the snow.

The evolution of mammals

The ancestors of mammals. Mammals *evolved* (developed gradually) from a group of reptiles called the *synapsids.* These reptiles arose during the Pennsylvanian Period (325 million to 286 million years ago). By the middle of the Permian Period (286 million to 248 million years ago), a branch of the synapsids called the *therapsids* had appeared. Over tens of millions of years, the therapsids developed many features that would later be associated with mammals. The therapsids are often referred to as the *mammallike reptiles.* One group of therapsids, the *cynodonts,* developed especially mammallike teeth, skulls, and limbs. Most scientists believe that the first mammals evolved from the cynodonts.

The first mammals probably split off from the cynodonts late in the Triassic Period (248 million to 213 million years ago). Numerous fossils from this period might be either early mammals or cynodonts. Scientists cannot be sure because many characteristics of mammals—such as hair, mammary glands, and warm-bloodedness—are not preserved in the fossil record.

By the start of the Jurassic Period (213 million to 145 million years ago), mammals had definitely evolved. They were tiny, shrewlike animals that probably ate insects and worms. Mammals remained fairly small throughout the Jurassic Period and the Cretaceous Period (145 million to 65 million years ago). Dinosaurs ruled the land during these periods. But many primitive

Methods of attack and defense

Mammals have various means of capturing prey and of defending themselves against enemies. The most important means include speed, concealment, and special protective body structures.

Jack Couffer, Bruce Coleman Inc.

A lion chases a waterbuck. In this contest, both mammals rely on speed—the lion to attack, and the waterbuck to escape. In most instances, a healthy adult waterbuck will escape.

George Schaller, Bruce Coleman Inc.

A tiger's striped coat provides almost total concealment in tall grass, enabling the animal to sneak up on its prey.

Leonard Lee Rue III, FPG

An armadillo's bony shell protects the animal like a suit of armor. When attacked, the armadillo curls up into a tight ball.

groups of mammals developed in Jurassic times. Most scientists believe that one of these early groups led directly to modern monotremes, though the fossil record of egg-laying mammals is extremely incomplete. Many other early groups died out in the Cretaceous Period. But one group, the *pantotheres,* probably gave rise to marsupials and placentals by the middle of the period.

The Age of Mammals began with the extinction of the dinosaurs at the end of Cretaceous times. During the Cenozoic Era (65 million years ago to the present), mammals became the dominant land vertebrates. By the end of the Eocene Epoch (55 million to 34 million years ago), all the modern *orders* (main groups) of mammals had developed. The modern families of mammals appeared during the Oligocene Epoch (34 million to 24 million years ago).

Mammals reached their greatest variety during the Miocene Epoch (24 million to 5 million years ago). The number of mammalian species began to decline during the Pliocene Epoch (5 million to 2 million years ago). The Pleistocene Epoch, which began about 2 million years ago, brought enormous changes in climate. Several waves of glaciers advanced over much of the land. Many mammals—including ground sloths, mammoths, saber-toothed cats, and woolly rhinoceroses—died out. Most of these extinctions were probably due to the changes in climate. But some might have been caused by a group of new, skillful predators—human beings.

The future of mammals. Although extinctions are a normal part of evolution, human beings have caused an increasingly rapid decline in the number of wild mammals. Human hunters have exterminated such mammals as the blaubok, also called the bluebuck, of Africa; the zebralike quagga; and Steller's sea cow. Human beings have also reduced the population of orangutans, rhinoceroses, tigers, and many other mammals to a size so low that these species might not survive in the wild.

Most large wild mammals are now few in number and confined to parks, some of which provide little protection or insufficient living space. Other large mammals are still hunted. Every year, people turn more and more wild lands into farms and towns, and so increasingly deprive mammals of living space. The survival of many wild mammals will depend on the establishment and careful management of large nature preserves and parks. Robert M. Timm and Barbara L. Clauson

A classification of mammals

Zoologists divide mammals into various orders of related species. The classification used here recognizes 26 orders of living mammals. The orders are listed according to their probable evolutionary development. Scientists disagree on the exact number of species recognized in each order.

WORLD BOOK illustrations by Jean Helmer and Paul Turnbaugh

Order Monotremata—monotremes. Primitive mammals that lay eggs. Mammary glands lack nipples. Teeth present only in young; adults have a long snout covered by leathery skin. Order consists of two species of echidnas and one species of platypus.

Echidna

Order Didelphimorphia—American opossums. A large group of marsupials, mammals whose young are poorly developed at birth. They have thick fur, a pointed snout, and medium to large eyes. The long tail is capable of grasping. Order consists of 66 species.

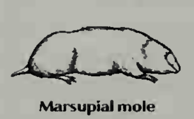
Opossum

Order Paucituberculata—caenolestids. South American insect-eating marsupials. These shrewlike mammals have a pointed snout; small eyes; a long, hairless tail; and no pouch. Order consists of seven species.

Shrew opossum

Order Microbiotheria—Order consists of only one species, the monito del monte, a small nocturnal marsupial with large eyes and a pointed snout.

Monito del monte



Order Dasyuromorphia—dasyurids. Varied group of meat-eating marsupials. Order consists of 64 species, including marsupial mice, quolls, the Tasmanian devil, and the extinct Tasmanian tiger.

Tasmanian devil

Order Peramelemorphia—bandicoots. Marsupials with a long snout and with hind legs longer than front legs. They often travel by hopping. Order consists of 22 species.

Bandicoot

Order Notoryctemorphia—Order consists of only one species, the marsupial mole, a burrowing marsupial that resembles a true mole. It has soft fur, a stumpy tail, and unusually large claws on the third and fourth fingers of the forefoot.

Marsupial mole

Order Diprotodontia—diprotodonts. Varied group of marsupials with a pair of enlarged incisor teeth in their lower jaw. They also have the second and third toes of their hind feet joined. Order consists of 131 species, including kangaroos, koalas, sugar gliders, and wombats.

Kangaroo

Order Xenarthra—xenarthrans (also called edentates). Mammals that lack teeth or have only small, peglike teeth. Forelimbs adapted for digging or for clinging to branches. Order consists of about 30 species of anteaters, armadillos, and sloths.

Armadillo

Order Insectivora—moles, shrews. Small mammals with teeth adapted for crushing insects and other invertebrates. Most have a pointed snout and five-toed feet. Order consists of more than 425 species, including hedgehogs, moles, and shrews.

Hedgehog

Order Scandentia—tree shrews. Small, squirrellike mammals with long snouts. They have strong claws on all toes and are excellent climbers. Order consists of 19 species.

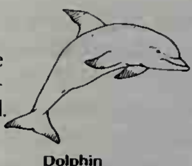
Tree shrew

Order Dermoptera—flying lemurs. Tree-dwelling Asian mammals with flaps of skin adapted for gliding. Order consists of two species of flying lemurs, also called colugos.

Flying lemur

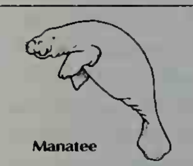
Order Chiroptera—bats. The only mammals that are capable of true flight, having forelimbs adapted as wings. Order consists of about 980 species of bats.

Bat



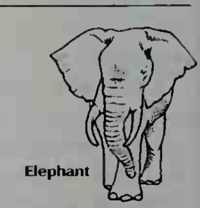
Order Primates—primates. Most species are tree dwellers. Hands have five fingers, and feet five toes. Many species have thumbs and big toes capable of grasping. Some have grasping tails. Order consists of more than 230 living species, including apes, human beings, lemurs, and monkeys.

Baboon



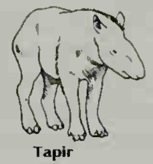
Order Carnivora—carnivores. Most are meat-eaters and have claws and large canine teeth. Order consists of about 260 species, including bears, cats, hyenas, raccoons, seals, skunks, walruses, and wolves. Seals and walruses are sometimes put in a separate order, Pinnipedia.

Wolf



Order Cetacea—cetaceans. Aquatic mammals with streamlined bodies, paddlelike forelimbs, no hindlimbs, horizontally flattened tail, and nostrils on top of the head. Order consists of about 80 species of dolphins, porpoises, and whales.

Dolphin



Order Sirenia—dugongs, manatees. Aquatic mammals with paddlelike forelimbs, no hindlimbs, horizontally flattened tail, and broad flattened muzzle. Order consists of five species.

Manatee

Order Proboscidea—elephants. Large, thick-skinned mammals. Nose and upper lip form trunk; upper incisors enlarged as tusks. Order consists of two species, the African elephant and Indian elephant.

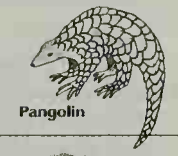
Elephant

Order Perissodactyla—odd-toed ungulates. Hoofed mammals with one or three toes on each foot. Axis of limb passes through middle toe. Order has about 17 species, including horses, rhinoceroses, and tapirs.

Tapir

Order Hyracoidea—hyraxes. Mammals with hooflike claws and a short tail. Order consists of seven species of hyraxes.

Hyrax



Order Tubulidentata—Order consists of only one species, the aardvark, a burrowing, insect-eating mammal with a long, piglike snout and long, sticky tongue.

Aardvark

Order Artiodactyla—even-toed ungulates. Hoofed mammals with two or four toes on each foot. Axis of limb passes between middle of toes. Order consists of about 220 species, including antelopes, bison, camels, cattle, deer, giraffes, hippopotamuses, hogs, pronghorns, and sheep.

Deer

Order Pholidota—pangolins. Toothless mammals covered with horny scales. A few hairs grow between scales. Order consists of seven species of pangolins.

Pangolin

Order Rodentia—rodents. Small, gnawing mammals with one pair of chisellike upper incisors; no canines. Order consists of more than 2,050 species, including beavers, gophers, mice, porcupines, rats, and squirrels.

Squirrel

Order Lagomorpha—lagomorphs. Small mammals with two pairs of upper incisors, no canine teeth, and molars without roots. Tail short or absent. Order consists of about 80 species of hares, pikas, and rabbits.

Hare

Order Macroscelidea—elephant shrews. Small, insect-eating mammals with a long, flexible, sensitive snout. Order consists of 15 species.

Elephant shrew

Mammary glands are special glands found in all mammals. In female mammals, the mammary glands produce milk. They are one of the major features that distinguish mammals from other kinds of animals.

In males, the mammary glands remain undeveloped. In female human beings, they enlarge and develop at the beginning of adolescence. The gland itself consists of several *lobes* (compartments) surrounded by cells of fat. The amount of fat determines the size of the mammary glands. The lobes are made up of smaller *lobules,* also called *acini,* which are lined by cells that secrete milk. Many *ducts* (tubes) are connected to these lobules. The ducts combine and form several main ducts that empty milk from the mammary glands at the nipple. Mammary gland development and milk production are

controlled by certain chemicals called *hormones.*

Mammography is the use of X rays to create images of the inside of the breast. Mammography is an important tool used by physicians to detect breast cancer. The images are taken with a special X-ray machine that presses the breast between two flat surfaces. The breast is compressed to spread the tissue so a lower dose of X rays can be used. The procedure produces a black-and-white image of the breast tissue called a *mammogram.* The mammogram is then examined by a *radiologist,* a physician trained in using images for medical diagnosis.

Doctors often order mammography to determine the cause of breast problems, such as a lump, breast pain, skin dimpling, or an abnormal discharge from the nipple. This type of mammography is called *diagnostic mammography.* Many abnormalities appear on a mammogram as a mass of little white flecks called *calcifications* or as an opaque mass. Most such abnormalities are *benign* (not cancerous). An abnormality's features indicate whether it is more likely benign or cancerous. Irregular, poorly outlined borders of a mass on the image can suggest cancer. Additional images and other tests are usually required to determine if cancer is present.

Screening mammography is performed to detect breast cancer in women who have no symptoms. Screening mammography is used to find breast cancers as early as possible, before tumor cells have *metastasized* (spread outside the breast). Among women over the age of 50, mammography can detect cancerous tumors in the breast 3 to 4 years before the tumor is large enough to be felt. Detecting cancer while a tumor is still small greatly increases the chances of a cure. Most doctors recommend that women begin having annual mammograms at age 40 to 50.

Standard mammograms, however, fail to detect about 15 percent of breast cancers. A new technique called *full field digital mammography* creates a computer image of the breast. Computer analysis of the mammogram allows more accurate detection and diagnosis of abnormalities in the breast. Suzanne J. Smith

Mammoth, *MAM uhth,* was a prehistoric animal closely related to present-day elephants. Mammoths were huge, lumbering beasts. Some measured more than 14 feet (4.3 meters) high at the shoulders. Mammoths had trunks and tusks. Many had tusks 13 feet (4 meters) long. The tusks curved down from the animal's upper jaw, then curved up and crossed in front of the trunk. Certain mammoths, called *woolly* or *hairy* mammoths, had long hair on their bodies, which helped protect them from the severe cold of the Pleistocene Epoch, a time marked by a succession of ice ages.

Mammoths rank among the most common fossils. The bodies of mammoths have been found perfectly preserved in ice in Siberia. Fossils of mammoths also have been found in Europe and in almost every state of the United States. Alaskan miners often find petrified mammoth bones and teeth when they pan for gold.

The oldest known mammoth bones date from 4 million years ago in Africa. Mammoths spread to other continents and reached North America about 1 $\frac{1}{2}$ million years ago, during the ice age, which ended about 11,500 years ago. Prehistoric people hunted them for food. Pictures of mammoths drawn by cave dwellers can be seen on cave walls in France. Most mammoths died out about 10,000 years ago. However, groups of smaller mammoths called dwarf mammoths survived much longer on isolated islands. One group, which lived on Wrangel Island off the northeast coast of present-day Siberia, died out only about 3,800 years ago. These dwarf mammoths reached only about 6 feet (1.8 meters) high at the shoulder. Michael R. Voorhies

Scientific classification. Mammoths belong to the elephant family, Elephantidae. They make up the genus *Mammuthus.*

See also **Fossil** (How fossils form); **Mastodon.**

Mammoth Cave National Park, *MAM uhth,* surrounds Mammoth Cave, part of the world's longest known cave system. The park lies in central Kentucky. The Green and Nolin rivers flow through it. Mammoth Cave National Park was established in 1941. For area, see **National Park System** (table: National parks).

Mammoth Cave is often called one of the wonders of the Western Hemisphere. The cave is in a ridge that consists mainly of limestone. Through millions of years, mildly acidic water trickled through cracks in the limestone and wore it away, forming the cave. Visitors can be guided through 12 miles (19 kilometers) of corridors on five levels in the cave. The lowest level lies 360 feet (110 meters) below the surface of the earth. Many rocks in the cave have interesting colors and shapes. These rocks resemble flowers, trees, and waterfalls.

The cave contains several lakes, rivers, and waterfalls. The largest river, Echo River, varies in width from 20 to 60 feet (6 to 18 meters) and in depth from 5 to 25 feet (1.5 to 8 meters). Strange eyeless fish live in Echo River (see **Cavefish**). These colorless creatures are about 3 inches (8 centimeters) long. Other blind creatures living in Mammoth Cave include beetles and crayfish. Several species of bats live in parts of the cave.

Historians believe that the first white people to see Mammoth Cave were local settlers who came to the area during the late 1700's. A deed filed in 1798 describes a large cave that probably was Mammoth Cave. But moccasins, simple tools, torches, and the remains of mummies found in the cave indicate that it was known to prehistoric Indians. Saltpeter, used to make gunpowder, was mined in the cave during the War of 1812. Mammoth Cave contained the only large supply of saltpeter that was known in the United States at that time. After the war ended, miners stopped working in the cave. It became a public showplace in 1816.

Another famous cave, Floyd Collins Crystal Cave, lies within the national park. Collins, a cave explorer, discovered Crystal Cave in 1917. Crystal Cave forms part of the Flint Ridge cave system, one of three cave systems in the park. The other two are the Joppa Ridge and the Mammoth Cave systems. In 1972, explorers discovered a connection between Mammoth Cave and the Flint Ridge cave system. The combined Mammoth-Flint Ridge cave system is the longest known cave system in the world. It has more than 300 miles (483 kilometers) of explored passages. Critically reviewed by the National Park Service

Man. See **Human being.**

Man, Isle of, is an island in the Irish Sea. It is a dependency of the British Crown and lies about halfway

between England and Ireland and about 20 miles (32 kilometers) south of Scotland. For its location, see **United Kingdom** (political map). The island has an area of 221 square miles (572 square kilometers) and a population of about 81,000. Most people have Celtic ancestry, and a few speak a Celtic language called *Manx* as well as English. A breed of cats called *Manx,* most of which have no tail, originated on the island (see **Cat** [picture]).

There are several theories about the origin of the island's name. One of the most widely held theories is that the name *Man* comes from the Celtic word *monadh,* meaning *mountain.* Most of the Isle of Man is covered by farmland and *moors* (wastelands of coarse grasses and evergreen shrubs called *heather*). A low mountain chain runs the length of the island. The highest peak, Snaefell, rises 2,034 feet (620 meters) above sea level. Douglas, the island's capital, lies on the east coast.

The Isle of Man is a popular summer resort for the people of the United Kingdom and Ireland. An international motorcycle race, held each June, is a major attraction. In addition to tourism, important industries include agriculture and fishing. In 1961, the Isle of Man greatly lowered its taxes on individuals and companies. The low taxes helped attract new residents and industries.

The Isle of Man was ruled at times by Ireland, Wales, Norway, Scotland, and England. Great Britain (now the United Kingdom) bought the island from local rulers in 1765 and has controlled it ever since. However, British laws do not apply to the island unless they specifically name it. A lieutenant governor represents the United Kingdom on the island. Tynwald Court, a 1,000-year-old parliament, regulates internal affairs. H. R. Jones

Man-of-war bird. See **Frigatebird.**

Managed care plans are health insurance plans that allow the insurer to influence the type of health care provided to patients. These plans differ from traditional *indemnity insurance plans.* In a traditional indemnity plan, the insurer gives the patient money for at least part of the cost of care. But the plan does little or nothing to influence the amount, price, quality, or type of care. Managed care plans have been widely adopted around the world as a way of controlling medical costs.

In the United States, the best-known types of managed care plans are (1) health maintenance organizations and (2) preferred provider organizations. Both types are private insurance plans.

Health maintenance organizations (HMO's) differ from traditional indemnity plans in that they not only finance health care, but also provide it. In return for premiums, an HMO promises to provide the patient with complete health care services. The HMO makes a profit only if the services it provides cost less than the premiums it receives. HMO's thus have a strong incentive to control health care costs. An HMO can control costs by keeping its members healthy, by providing care in a cost-efficient way, or by limiting the services it provides.

An HMO may employ doctors, nurses, and other health care professionals directly. Or it may enter into contracts with providers who agree to furnish medical care to members of the HMO for a set fee per patient.

Preferred provider organizations (PPO's) are groups of doctors or other health care providers who make special contracts with insurers. Under these contracts, the providers promise to give medical care at a price negotiated with the insurer. The price is typically lower than that charged by other health care providers. The insurer's contract with its patients encourages them to seek care from providers who belong to the PPO. For instance, the contract may require the insurer to pay 90 percent of the cost if the provider is affiliated with the PPO but only 70 percent if the provider is not affiliated.

The managed care debate. Many Americans have doubts about the quality of care given by managed care plans. Some patients and doctors fear that cost-control incentives limit the quality of care provided. For instance, critics claim that managed care plans have a financial incentive to rush a patient home from the hospital after an operation or other medical procedure.

Some laws in the United States require managed care plans to provide certain minimum levels of care to patients who suffer from particular conditions. For example, one federal law requires insurance plans to pay the cost for mothers and their newborns to stay in the hospital for at least 48 hours after the baby's birth.

Despite the criticism of managed care, some people believe the plans provide excellent health care. These people point out, for instance, that many plans give their doctors treatment guidelines that are regularly updated to incorporate advances in medical science.

In other countries, managed care plans may take the form of national health insurance programs that pay for the health care of almost all the country's people. One such country is the United Kingdom. There the government pays the salaries of most doctors and owns and funds most of the hospitals. In Canada, the provinces and federal government share the cost of most health care services. Canada's provincial governments affect the delivery of health care in a number of ways. For example, they control the number of doctors and the availability of expensive, hospital-based medical equipment. Australia has a national health insurance system that provides basic health care for all of its citizens. Private insurance companies offer coverage for care not provided by the Australian government. Mark J. Browne

See also **Insurance** (Private health insurance).

Management. See **Industry** (Management); **Personnel management.**

Management and Budget, Office of (OMB), is a United States government agency that helps the president prepare the federal budget and evaluate government programs and organization. It determines the performance and objectives of each government program and recommends to the president how much money the government should spend. It also reviews and approves all regulations issued by agencies of the executive branch. Other functions of the OMB include improving the financial management of government agencies and improving government organization and administrative management. The OMB issues *The Budget of the United States Government* and other publications.

Before 1970, the OMB was known as the Bureau of the Budget. The bureau was created in 1921 as part of the Treasury Department. It became a part of the Executive Office of the President in 1939.

Critically reviewed by the Office of Management and Budget

See also **Congressional Budget Office.**

Management information systems are computer systems designed to aid the executives who run busi-

nesses, government agencies, and other organizations. Management information systems help managers make complex business decisions.

The establishment of a management information system involves the preparation of specific *programs* (sets of instructions) for the computer. For example, one program might call for the computer to issue *exception reports.* These reports list any unusual developments, such as products with very low or very high sales. In most cases, computer specialists develop programs from information provided by managers.

Management information systems may be used to handle *programmable* or *nonprogrammable* decisions. Programmable decisions are simple decisions that a computer can make by itself, using the data it receives. For example, a management information system can determine how often to order supplies by processing information about rates of use and storage costs. Nonprogrammable decisions are more complex and require an exchange of information between human managers and the computer system. For example, a manager's decision to increase prices might hinge on the computer's analysis of how rising costs will affect sales.

Richard M. Hodgetts

Managua, *mah NAH gwah* (pop. 903,100), is the capital, largest city, and chief commercial center of Nicaragua. It lies on the southern shore of Lake Managua in western Nicaragua (see **Nicaragua** [map]).

Managua was severely damaged in 1972 by an earthquake that killed about 5,000 people and destroyed almost the entire downtown area. Today, the city has no central business district. The former downtown section consists of empty fields, except for those now used as sports fields or as sites for monuments honoring national heroes. A few concrete buildings survived the earthquake. These include the Palace of the Heroes of the Revolution, the Presidential Palace, and the badly damaged Metropolitan Cathedral.

Since the earthquake, residential and business areas have been built on the outskirts of Managua. Large villages of housing units were built for thousands of families left homeless by the earthquake. Other new construction included schools, hospitals, and shopping centers. These buildings were specially constructed to withstand severe earthquakes.

Managua's economy is based mainly on trade. The city is Nicaragua's chief trading center for coffee, cotton, and other crops. It is also an important industrial center. Its chief products include beer, coffee, matches, textiles, and shoes.

Managua was built in the 1850's on the site of an Indian community. The city occupies an area on a *fault* (break in the earth's crust) and suffered a major earthquake in 1931 as well as in 1972. *Seismologists* (scientists who study earthquakes) predict that Managua will continue to experience a severe earthquake every 50 years or less. Nathan A. Haverstock

See also **Nicaragua** (picture).

Manakin, *MAN uh kihn,* is a type of small, tropical bird. There are more than 50 species of manakins. They live in woodlands and forests from Mexico to Argentina. These birds are extremely active and show little fear of people. Most manakins measure less than 5 inches (13 centimeters) long.

© John S. Dunning, Photo Researchers

The manakin is a small bird found in the tropical forests of Central and South America. The male, *shown here,* has brilliantly colored feathers. The female's feathers are generally olive-green.

Manakins have a chunky body with a short, broad bill and short wings. Most species have a short tail, but a few have longer tail feathers. The males of most species have a bold color pattern. They are partly black or olive-brown and partly brightly colored in red, yellow, or blue feathers. Females are olive-green in color.

Male manakins perform elaborate courtship rituals to attract females. They often produce unusual sounds with their wings as part of these rituals. In some species, the male does a solitary hopping or flying dance. Other species are known for displays in which many males gather on a specially selected dancing ground called a *lek.* There they perform courtship displays in competition with each other. The female manakin visits the lek and selects a mate as the males perform. Once mating occurs, the female builds a nest and raises the family alone, while the male continues to court other females.

Manakins feed mainly on insects and small fruit. Recent studies indicate that some manakins may live more than 20 years. Most other birds of similar size have a much shorter life span. Donald F. Bruning

Scientific classification. Manakins make up the family Pipridae.

Manama, *muh NAM uh* (pop. 121,986), is the capital, largest city, and chief port of Bahrain, an island nation in the Persian Gulf (see **Bahrain**). Manama lies on the northern tip of the country's main island, which is also called Bahrain.

Manama was probably founded in the 1300's. It became an important port, largely because it lies along major trade routes. Today, the city is a major center of trade, finance, and shipping for the Persian Gulf region. It has numerous warehouses, banks, and stores, as well as modern hotels and government offices. About 40 percent of Bahrain's people live in Manama.

In 1962, the government of Bahrain opened a new harbor for Manama. This harbor is suitable for modern ocean vessels. Manama has been developing its industries since the mid-1900's. These industries include the

construction and repair of ships. Robert Geran Landen

Manassas, Battles of. See **Civil War** (First Battle of Bull Run; Second Battle of Bull Run; table: Major battles).

Manatee, *MAN uh TEE,* sometimes called *sea cow,* is a large water mammal. It belongs to the same group of mammals—the order *Sirenia*—as the dugong. There are three species of manatees. The *Caribbean manatee* lives in the Caribbean Sea and along the northeastern coast of South America. It is also found in the coastal waters of the Southeastern United States, particularly in the bays and rivers of Florida. The *Amazon manatee* is only found in fresh water. It dwells in the Amazon and Orinoco river systems. The *African manatee* lives in the rivers and coastal waters of western Africa. All three species have been hunted for their flesh, hide, and oil, and are endangered or threatened.

The manatee feeds on water plants. Its upper lip is divided into halves, which close like pliers on the plants. A manatee can consume more than 100 pounds (45 kilograms) of plants in a day. In Guyana, manatees have been used to keep waterways free of weeds.

A manatee has light to dark gray skin, with bristly hairs scattered over its body. Its front legs are paddle shaped, and its tail is rounded. It has no hind legs. The Caribbean manatee may grow to 13 feet (4 meters) long and weigh up to 3,500 pounds (1,600 kilograms).

Daniel K. Odell

Scientific classification. Manatees make up the genus *Trichechus* in the family Trichechidae. The Caribbean manatee is *T. manatus;* the Amazon manatee, *T. inunguis;* the African manatee, *T. senegalensis.*

See also **Animal** (picture: Animals of the ocean); **Dugong; Sea cow; Sirenia.**

Manchester (pop. 397,400; met. area pop. 2,445,200) is one of the largest cities in England, one of the political divisions of the United Kingdom. Manchester is the center of England's third largest metropolitan area. Only the metropolitan areas of London and Birmingham have more people. Manchester is the main city of Greater Manchester County, one of the United Kingdom's chief economic centers. The city is on the Irwell River about 35 miles (56 kilometers) east of the Irish Sea, an arm of the Atlantic Ocean (see **England** [political map]). The Manchester Ship Canal links the city to the mouth of the Mersey River, which flows into the Irish Sea. The canal makes Manchester an inland port.

The city. Manchester Cathedral, a famous city landmark, was built in the 1400's. Manchester also has many buildings that date from the 1800's, when the city became a major industrial and trade center. These buildings include the magnificent Town Hall, built in 1877. A number of the buildings constructed during the 1800's to serve the needs of industry and trade are now used for other purposes. For example, the Royal Exchange, formerly a trading center for the British cotton industry, is now a theater. Bridgewater Hall, a concert hall built in 1996, is the home of the world-famous Hallé Orchestra. The Imperial War Museum North, housed in a striking metal-clad building on the banks of the ship canal, opened in 2002.

During the 1970's, a huge educational district was developed south of Manchester's downtown area. The district is more than 2 miles (3.2 kilometers) long and includes two universities, a technical school, a college of music, and a college of education.

Economy. Manchester is one of the United Kingdom's chief centers of trade and finance. Its port handles about 14 million tons (13 million metric tons) of cargo annually. The city has many banks and insurance companies and a stock exchange. The Manchester area is also a leader in manufacturing. Products include chemicals, clothing and textiles, computers, electronic equipment, industrial machinery and machine tools, paper, precision instruments, and processed foods. Manchester has an international airport. The city is a center of railroad transportation and of radio and television broadcasting.

History. About A.D. 80, Roman soldiers built a fort on the site of what is now Manchester. Anglo-Saxons from northeastern England established a village there about 700. By the 1500's, Manchester had become an important center for the wool trade.

During the 1800's, Manchester developed into one of the world's chief centers for the production of cotton textiles. The city and its surrounding communities grew into a major industrial area. Large numbers of people moved there to find jobs. The Manchester Ship Canal opened in 1894 and made the city an inland port. The production of cotton textiles declined steadily during the first half of the 1900's. However, the development of other businesses in the city and surrounding communities helped the area retain its economic importance.

In the late 1990's, Manchester undertook a major rebuilding and restoration project in its downtown area. In June 1996, a bomb planted by the Irish Republican Army (IRA) near the Arndale shopping center in downtown Manchester injured more than 200 people and damaged many buildings. Anthony Sutcliffe

Manchester, New Hampshire (pop. 107,006; met. area pop. 198,378), is the state's largest city and chief manufacturing and financial center. It lies on the banks of the Merrimack River in south-central New Hampshire (see **New Hampshire** [political map]). The Uncanoonuc Mountains curve around the western part of the city.

Nearly 10 percent of the people of Manchester are foreign-born. About a fourth of the population are of French-Canadian ancestry.

The city is the home of the Manchester Institute of Arts and Sciences, the Currier Gallery of Art, the Association Canado-Américaine, and the Carpenter Memorial Library. New Hampshire, Notre Dame, and St. Anselm colleges and a campus of the University of New Hampshire are also in the city. The home of General John Stark, a figure of the Revolutionary War in America (1775-1783), is in the city.

Manchester was once known as the home of the largest cotton mills in the world. The mills failed in the 1930's. Today, the city's chief products include boots and shoes and cotton and woolen goods. It is an insurance center and distributing point. The city is served by Manchester Airport, several bus lines, and a freight railroad. No railroad passenger trains stop in Manchester.

Manchester's first white settlement was started in 1722. Manchester was first called Harrytown, and then Derryfield. It received its present name in 1810. Manchester became a city in 1846. It has a mayor-council form of government. Donald C. Anderson

Manchester terrier is a breed of dog that originated in Manchester, England, in the 1800's. Dog breeders

produced the terrier to compete in rat-killing matches. In these matches, people bet on how many rats a dog could kill in a given period. By mating the black-and-tan terrier, an excellent ratcatcher, with the swift whippet, the breeders hoped to produce a superior ratter. Today, Manchesters are popular house pets. They are loyal to their owners and make excellent watchdogs.

Manchesters have a smooth, black coat; and a tan mark over each eye, on each cheek, and on the chest. The front of the forelegs and the inside of the hind legs are tan with black markings. The ears are set high on the long, narrow head. The dog has a whiplike tail.

The Manchester terrier has two varieties—the standard and the toy. The standard Manchester weighs 12 to 22 pounds (5.4 to 10 kilograms). Its ears may naturally stand erect or may fold over, with the tips falling to the front. Some owners have the ears *cropped* (cut) to make them stand straight up. The toy Manchester weighs 5 to 12 pounds (2.3 to 5.4 kilograms). Its ears are naturally erect. The toy was bred from the standard.

Critically reviewed by the American Manchester Terrier Club

See also **Dog** (picture: Terriers).

Manchuria, *man CHOOR ee uh,* is the historical name of a region in northeastern China. Today, Manchuria is called the Northeast or *Dongbei.* The region contains rich natural resources, especially coal and iron. Much of China's heavy industry centers around Changchun, Harbin, and Shenyang. The region also produces much of China's food. Manchuria consists roughly of the Chinese provinces of Heilongjiang, Jilin, and Liaoning; and the northeastern part of Inner Mongolia, a self-governing region of China. Manchuria covers about 475,000 square miles (1,230,000 square kilometers).

People. Manchuria has a population of over 100 million. About 90 percent of the people are descendants of Chinese who migrated to Manchuria between 1880 and 1930. Manchus, the original people of Manchuria, make up about 5 percent of the region's population. Smaller population groups include Koreans and Mongols. Large numbers of these minority peoples have been absorbed into Chinese society through intermarriage and public education. Today, almost all the people of Manchuria speak Northern Chinese (Mandarin), the official language of China. They follow Chinese customs and live as do the people of most other parts of China.

Land and climate. A broad central plain makes up most of Manchuria. Forested mountains border the plain on the east, north, and west. In the south, the Liaodong Peninsula extends into the Yellow Sea. The Amur and Ussuri rivers separate Manchuria from Russia on the northeast. Korea lies across the Yalu River to the southeast. Manchuria has long, cold winters and short, hot summers.

Economy. Manchuria has rich deposits of coal and iron, both used in making steel. Its factories make such steel products as machinery, railroad equipment, tools, and trucks. They also produce cement, chemicals, electrical equipment, and paper. Grains, especially sorghums and soybeans, make up much of Manchuria's agricultural production. The region's farmers also grow cotton, sugar beets, and tobacco. Manchuria has reclaimed large areas of wasteland for farming by using irrigation and other methods. Dalian, one of China's busiest ports, lies in the southern part of Manchuria.

History. In early times, Manchu warriors on horseback frequently invaded and conquered parts of China. The Manchus conquered northern China in 1644, and gradually extended their control to the whole country. The Manchus ruled until 1912. Chinese rulers since 1912 have looked upon Manchuria as part of China.

Russia expanded across Asia during the 1800's and seized land from China. In 1860, Russia and China signed an agreement giving Russia all the territory north of the Amur River and east of the Ussuri River. In 1896, China agreed to permit Russia to build the Chinese Eastern Railway across Manchuria to the Russian port of Vladivostok. Two years later, Russia leased land on the Liaodong Peninsula and built a naval base at Lüshun and a port at Dalian.

In the Russo-Japanese War (1904-1905), Japan defeated Russia and took control of the Liaodong Peninsula. In 1931, the Japanese conquered the rest of Manchuria. They made the region a puppet state called *Manchukuo.* During World War II (1939-1945), Manchuria was an important industrial base for Japan.

During the last days of World War II, the Soviet Union—which had been formed in 1922 under Russia's leadership—declared war on Japan and occupied Man-

Manchuria

This map shows Manchuria, now called the Northeast or *Dongbei.* It is located in the northeastern part of China.

churia. Before returning Manchuria to China in 1946, the Soviet Union helped the Chinese Communists seize power. The Communists conquered all of China in 1949.

During the 1960's, China claimed some Soviet territory beyond Manchuria. In 1969, China and the Soviet Union clashed over control of several islands in the Amur and Ussuri rivers. The fighting stopped after the countries agreed to discuss their differences. But when the Soviet Union broke up in 1991, the border claims had not yet been settled. Russia and China continue to negotiate to settle the claims. Richard Louis Edmonds

Manchus, *MAN chooz,* were a people who conquered China in the 1600's. They invaded from Manchuria, in what is now northeast China, in 1644. They established the *Qing (Pure)* dynasty that year and gradually took control of China. The Qing dynasty prospered in the 1700's but declined in the 1800's. It ended in 1912, when the Chinese overthrew the Manchus.

Manchu rulers forbade marriage between Manchus and the Chinese until the early 1900's. Since then, many Manchus and Chinese have intermarried. Most Manchus now have taken Chinese names. The Manchus are descended from a people called the Jurchen (also spelled Juchen). The Jurchen, who also came from Manchuria, had occupied all of northern China by 1127 and ruled the area until 1234. Richard L. Davis

Mandalay, *MAN duh LAY* (pop. 472,512), is Myanmar's second largest city and chief inland river port. Only Yangon has more people. Mandalay lies in central Myanmar on the Irrawaddy River (see **Myanmar** [map]). It is known for its old pagodas, temples, and monasteries. It is the home of the Mandalay Arts and Science University.

Mandalay was founded in 1857. It was the capital of Myanmar (then called Burma) from 1860 to 1885, when the British captured the city. The British moved the capital to Yangon, also spelled Rangoon. Mandalay suffered much damage during World War II (1939-1945).

James F. Guyot

Mandamus, *man DAY muhs,* is a court order that requires a person, lower court, government official, or an officer of a corporation to do a legal duty. On many occasions, a public official may be required to perform an act, such as to make a commission or sign a paper. If the official refuses to do the act, a *writ of mandamus* may be sought, and a court may order the official to do the act. Mandamus can be obtained only where the law says the official must do the act, but not where the law says the official may decide whether to do it or not. In such a case, a court will not compel the official to decide in favor of the person seeking the writ of mandamus. But the court may compel the official to decide one way or the other. See also **Injunction; Writ.** Paul C. Giannelli

Mandan Indians are a tribe that has lived in western North Dakota, along the Missouri River, for more than 500 years. The Mandan were originally village dwellers and lived in large, earth-covered lodges. They hunted and also cultivated fields of beans, corn, squash, sunflowers, and tobacco. The early Mandan exchanged their crops for goods that other tribes brought to their villages. During the 1700's, the Mandan began to trade with European explorers and traders.

In 1837, a smallpox epidemic nearly wiped out the Mandan. The survivors found refuge in the nearby villages of the Arikara and the Hidatsa tribes. From the 1840's to the 1860's, the three tribes settled on what is now the Fort Berthold Reservation in North Dakota.

In the late 1800's, the U.S. government began to divide the reservation into small parcels of land, which were assigned to each eligible Arikara, Hidatsa, and Mandan. The three tribes then left their villages and moved to their assigned lands. In the late 1940's, the government took about a fourth of the reservation to build Garrison Dam, a huge hydroelectric project. Indian families who lived on this land had to settle elsewhere on the reservation. Today, about 400 Mandan live there. Most are farmers or ranchers. Beatrice Medicine

Oil painting on canvas (1832) by George Catlin; National Museum of American Art, Smithsonian Institution, Gift of Mrs. Sarah Harrison

A Mandan medicine man, wearing moccasins with attached foxtails, holds ceremonial pipes decorated with feathers.

Mandarin, *MAN duhr ihn.* English-speaking people used the name *mandarin* for any high military or civil official of the Chinese Empire. The Chinese term is *guan,* which means *a public official.* The dialect of North China, the language these officials spoke, is called *Northern Chinese* or *Mandarin.* The Chinese call the dialect *putonghua,* meaning *common language.* Today it is China's official language. See **Chinese language.**

A Chinese became a mandarin by taking promotional examinations. He showed his rank by the color of the buttons on his cap. Governors and generals had red coral buttons. Lieutenant governors and judges wore blue ones. Lower officers had other colors.

Each mandarin had an official robe. The military man's robe had beasts embroidered on it. The civil official's robe was illustrated with decorative birds. Judges wore plainer robes.

A mandarin could not marry or acquire property in the province to which he was sent. He could not serve over three years in one province. Richard L. Davis

Mandarin, *MAN duhr ihn,* is a citrus fruit that has a sweet, juicy pulp. Most varieties have an orange-colored rind that separates easily from the edible interior. In the United States, mandarins are called *tangerines.* Mandarins and mandarin hybrids form a large group of citrus fruits. Hybrids include the *tangelo,* a cross with a grapefruit, and the *tangor,* a cross with an orange.

Mandarins originated in Southeast Asia. They are now grown in Brazil, China, Italy, Japan, Spain, and other countries. In the United States, Arizona, California, and Florida are the leading mandarin-producing states.

Wilfred F. Wardowski

Scientific classification. Mandarins belong to the rue family, Rutaceae. They are *Citrus reticulata.*

See also **Tangelo; Tangerine; Tangor.**

Mandated territory. After World War I ended in 1918, certain colonies and territories were taken from the defeated nations and placed under the administration of one or more of the victorious nations. These areas were called *mandated territories.* The League of Nations, a forerunner of the United Nations (UN), supervised the governing countries in the administration of the territories. The League expected the governing countries to improve living conditions in the territories, and to prepare the people for self-government.

Britain received mandates for Mesopotamia (later renamed Iraq); Tanganyika (now part of Tanzania); and Palestine. Palestine was later divided into Palestine and Transjordan (later renamed Jordan). France received Syria, which was later divided into Syria and Lebanon. Both Britain and France were given parts of the Cameroons and Togoland. Belgium received Ruanda-Urundi. Japan was given German islands in the North Pacific Ocean. Australia received German islands in the South Pacific, including the northeastern section of New Guinea and Nauru. New Zealand received Western Samoa (now Samoa) and the Union of South Africa (now called South Africa) received German Southwest Africa (now called Namibia).

The mandate system ended in 1947. By that time, several mandated territories, including Iraq, Syria, Lebanon, and Jordan, had become independent countries. The remaining territories, except Namibia, were placed under the stronger United Nations trusteeship system. The same countries continued to administer the territories, but they were under the control of the UN. Namibia became independent in 1990. Anthony D'Amato

Mandela, *man DEHL uh,* **Nelson** (1918-), was president of South Africa from 1994 to 1999. He was the country's first black president. Mandela was elected by the country's National Assembly. The Assembly had been chosen in South Africa's first elections in which the country's blacks were allowed to vote. Blacks won a majority of the Assembly seats, and the Assembly selected Mandela as president. These developments marked the beginning of a new era in South Africa. They resulted in blacks gaining control of the government after a long period of domination by the white minority.

Since 1991, Mandela had served as president of the African National Congress (ANC), a largely black group that opposed the South African government's policy of rigid racial segregation called *apartheid.* He had long been a leader of protests against apartheid and was imprisoned in 1962 on charges of conspiring to overthrow the white-minority government. While in prison, he became a symbol of the struggle for racial justice. After being freed in 1990, he led negotiations with white leaders that eventually brought an end to apartheid and established a nonracial system of government.

Mandela and then-President F. W. de Klerk of South Africa won the 1993 Nobel Peace Prize. They were honored for their work to end apartheid and to enable the country's nonwhites to fully participate in the South African government.

Early life. Nelson Rolihlahla Mandela was born in Umtata, in the Transkei territory of South Africa. His father was a chief of the Xhosa-speaking Tembu tribe. Mandela gave up his right to succeed his father and instead prepared for a legal career. He attended the University College of Fort Hare, studied law by correspondence at Witwatersrand University, and received a law degree from the University of South Africa in 1942. That year, in Soweto, he and a friend opened the first black law partnership in South Africa.

Imprisonment. Mandela joined the ANC in 1944 and helped form the organization's Youth League. In 1948, the South African government established its policy of apartheid. The ANC called for equality for all races and began leading open resistance to the government. In 1956, the government charged Mandela with treason and other serious crimes, but he was found not guilty in 1961. The government had outlawed the ANC in 1960, but Mandela renewed the protests and went into hiding. He was arrested in 1962, convicted of sabotage and conspiracy, and sentenced to life in prison.

While Mandela was in prison, growing antiapartheid forces in South Africa argued that he should be freed. His wife at that time, Winnie Mandela, became a leading spokesperson for his cause. Shortly before Mandela's release in 1990, the government recognized the ANC as a legal political organization.

End of white rule. After leaving prison, Mandela agreed to suspend an armed struggle the ANC had been waging against the South African government. Over the objections of more radical ANC members, he urged conciliation with South African President de Klerk and other government leaders. He sought to obtain political power for the country's blacks in a peaceful way.

Nelson Mandela

In 1990 and 1991, the government repealed the laws that formed the legal basis of apartheid. But Mandela also negotiated an end to other forms of racial injustice, including laws that denied blacks the right to vote in national

and provincial elections. The first truly open national elections in which all races could vote were held in April 1994. The ANC won a majority in the country's National Assembly, and Mandela became president. Mandela stepped down as head of the ANC in 1997.

In 1992, Mandela announced that he and his wife, Winnie, had agreed to separate. The couple was divorced in 1996. In 1998, Mandela and Graca Machel, the widow of President Somora Machel of Mozambique, were married. Sanford J. Ungar

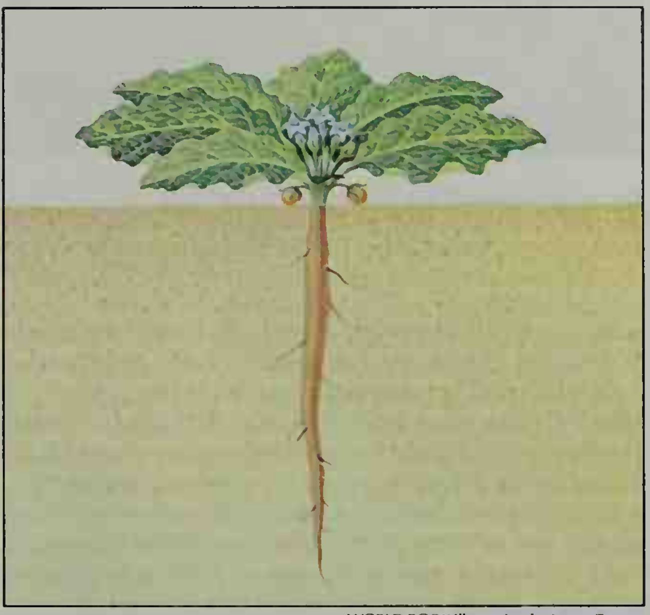
Mandingo, *man DIHNG goh,* is the name of a group of west African people. The Mandingo are descendants of the founders of the powerful Mali Empire. Most of the 1 $\frac{1}{2}$ million Mandingo live in Mali, but many live in Côte d'Ivoire, Gambia, Guinea-Bissau, and Senegal. The Malinke are the most important Mandingo group. The Mandingo speak a language that belongs to the *Mande* language group.

During the 1200's, Mande-speaking people lived in independent states in Africa. The largest and most famous Mandingo state, the Mali Empire, flourished from about 1240 to 1500. Its leaders converted to Islam, the religion of the Muslims, but few of the Mandingo people became Muslims. Today, many Mandingo still practice traditional African religions. Most of the rural people are farmers or cattle herders, though many city dwellers are traders or artists. Leo Spitzer

Mandolin, *MAN duh lihn,* is a stringed musical instrument. It has a narrow, *fretted* (ridged) neck attached to a pear-shaped body that resembles the body of a lute. Most mandolins have four pairs of strings. Others have five pairs. The strings run from the top of the neck to a low bridge near the bottom of the body. The player strums the strings with a *plectrum* (pick) held between the thumb and index finger of the right hand. With the fingers of the left hand, the player presses down the strings along the neck to vary the pitch. During the 1700's, the mandolin gained some use in classical music. Today, it is primarily played in popular music.



Abram Loft

David R. Frazier

The mandolin has been popular for hundreds of years, particularly among southern Europeans and Latin Americans.

Mandrake is the name of two similar plants that belong to the nightshade family. Mandrakes grow wild in southern Europe and Asia. The stem of a mandrake cannot be seen, and the leaves seem to grow from the roots. Most mandrakes have one large, thick root that tapers to a point. The white, bluish, or purple flowers of a mandrake grow on slender stalks among the leaves.

WORLD BOOK illustration by James Teason

A mandrake has a large, thick root. Some people believe these roots have magical and medicinal properties.

People have had superstitious beliefs about the mandrake since early times. The plant contains *scopolamine* and *hyoscyamine,* two chemical compounds that may be used as medicines or poisons. Ancient peoples of the Near East and Europe used the root of the plant as a narcotic and anesthetic. Some people thought mandrakes were magical plants and used them in so-called *love potions.* Mandrakes are mentioned in the Bible and in the Ebers Papyrus, an Egyptian medical text which dates from about 1550 B.C. or earlier. The Egyptians probably used the plant to prepare sedatives and pain-relieving drugs. Today, some people may still use the plant's root in drinks believed to have magical effects.

John E. Averett

Scientific classification. Mandrakes are in the nightshade family, Solanaceae. The two species of mandrakes are *Mandragora autumnalis* and *M. officinarum.*

Mandrill, *MAN druhl,* is a colorful monkey that lives in the forests of Cameroon and other parts of western Africa. Male mandrills are among the largest monkeys, weighing as much as 90 pounds (41 kilograms). Female mandrills weigh half as much. Mandrills resemble baboons, having long arms, small, piglike eyes, large canine teeth, and a muzzle similar to that of a dog. The

George H. Harrison from Grant Heilman

The male mandrill has vivid coloring that helps make it one of the most unusual looking monkeys. The colors become even more brilliant when this west African monkey is excited.

male mandrill is especially colorful. Its cheeks are blue; its long, flat nose is red; and its rump is red and blue.

Like most other monkeys, mandrills live in groups. Mandrill groups range from 15 to 95 individuals, though as many as 150 mandrills may band together for short periods of time. Males protect the group against leopards and other enemies. Mandrills move about on the ground and in trees. They feed on vegetation—especially fruits—and many kinds of insects. In captivity, mandrills have lived for more than 40 years.

Scientific classification. The mandrill belongs to the Old World monkey family, Cercopithecidae. It is *Mandrillus sphinx.*

Maned wolf. See Fox (South American "foxes").

Manet, *ma NAY,* **Edouard,** *ay DWAR* (1832-1883), a French painter, helped break tradition by using his subject matter in unexpected ways. His subjects often combine elements of traditional art with themes from the life of his time. Manet also painted in a bold, simplified manner, stressing the general visual effect. Since Manet's time, painting has been dominated by this concern with the importance of the picture itself, rather than with the picture's storytelling function.

Manet is often identified with the impressionist style of painting, and he and the impressionist artists influenced each other. However, Manet refused to exhibit his works in impressionist shows. The public considered impressionism revolutionary and treated it hostilely. Manet preferred to seek popular success by exhibiting in conservative shows sponsored by the government.

Manet was born in Paris. From 1850 to 1856, he studied with the skillful but traditional artist Thomas Couture. From Couture, Manet learned how to use outline expressively, how to obtain a lively effect with broken brushstrokes, and how to achieve strong lighting with a minimum of tones. Manet wanted to use this technical knowledge in order to portray modern life in a spontaneous way.

In 1863, Manet shocked the people of Paris with his painting *Luncheon on the Grass.* This picture shows a female nude at a picnic with two men who are wearing modern clothing. Many people felt that the painting was indecent. In 1865, Manet's *Olympia,* a painting of a female nude, created an even greater scandal. The public objected to the nude's bold pose, to her direct and outward gaze, and to the picture's severe lighting contrasts and flat silhouetted forms.

During the 1860's, Manet also painted scenes from modern history, though Biblical and ancient historical scenes were popular at the time. One painting shows

Courtauld Institute Gallery, London

Art Institute of Chicago

Edouard Manet completed *Bar at the Folies Bergère, left,* in 1882. The painting shows the firm modeling and bright, vivid colors that are typical of much of his work. The portrait of Manet, *above,* was painted by his friend Henri Fantin-Latour in 1867.

the execution of Emperor Maximilian of Mexico in 1867. Another of Manet's modern historical scenes, *Combat of the Kearsarge and the Alabama* (about 1865), shows a naval battle of the American Civil War. It is reproduced in the **Alabama** (ship) article.

Manet's last great painting was *Bar at the Folies Bergère* (1882). This work is remarkable for its dazzling color, rich textures, and detailed portrayal of Parisian society. Manet died on April 30, 1883. Richard Shiff

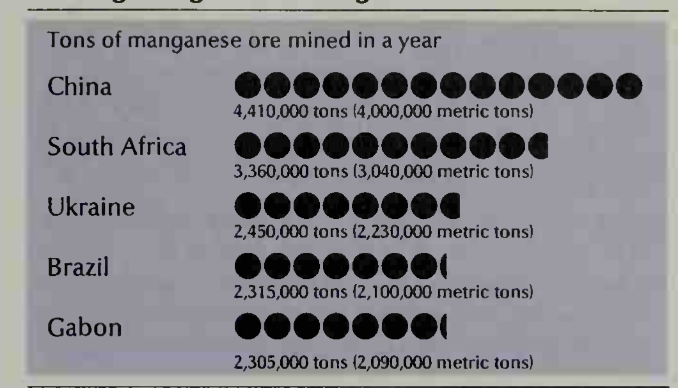
Manganese, *MANG guh neez,* is a brittle, silver-gray metallic element. All plants and animals require small amounts of it. Manganese is also an important substance in steel and has many other industrial uses.

Manganese is plentiful in Earth's crust. It occurs only in combination with other elements, mainly in the minerals braunite, hausmannite, manganite, psilomelane, pyrolusite, and rhodochrosite. It was first isolated in 1774 by Johan Gottlieb Gahn, a Swedish chemist.

In living things, manganese is a part of many proteins and *enzymes.* An enzyme is a protein that serves as a *catalyst,* a substance that speeds up chemical reactions. One manganese enzyme is called *superoxide dismutase.* This enzyme protects living tissue from *superoxide,* an electrically charged oxygen molecule. Cells produce superoxide during *respiration,* the process by which living things obtain and use oxygen. Manganese also plays an important role in *photosynthesis,* the process by which plants produce food.

In human beings and other animals, a lack of manganese disrupts growth and results in disorders of the bones and central nervous system. A diet that includes beans, nuts, green leafy vegetables, or whole grain and cereals provides adequate amounts of manganese.



Industrial uses. Industry uses most manganese in *alloys* (metal mixtures) and compounds. About 95 percent of the manganese in ores is used to make *ferromanganese.* This alloy with iron contains about 80 percent manganese and is used in refining steel. Manganese strengthens steel—itself an alloy—by removing oxygen and sulfur from it. Bubbles of oxygen weaken steel. Sulfur increases steel's tendency to break during the *forging process,* in which the metal is heated and shaped.

All steel has some manganese. *Manganese steel* contains as much as 14 percent manganese. It is extremely durable, so it is used for heavy-duty machinery and safes. Manganese makes *stainless steel* and various alloys of aluminum, copper, and magnesium harder and more resistant to rust.

The most widely used compound of manganese is *manganese dioxide.* Applications include dry cell batteries, paints and dyes, glass, and photographic developer. It also gives bricks a red to brown color. *Manganese sulfate* is used in the production of paint and varnish driers. *Potassium permanganate* serves as a disinfectant and deodorizer. It is also used in water purification and in the production of the artificial sweetener saccharin.

Properties. Manganese belongs to the group of chemical elements called *transition metals* (see **Element, Chemical** [Periodic table of the elements]). Its *atomic number* (number of protons in its nucleus) is 25. Its *relative atomic mass* is 54.938049. An element's relative atomic mass equals its *mass* (amount of matter) divided

Leading manganese-mining countries

Figures are for 1998.
Source: U.S. Geological Survey.

by $\frac{1}{12}$ of the mass of an atom of carbon 12, the most abundant form of carbon. Manganese melts at 1246 ± 3 °C and boils at 2062 °C. Its chemical symbol is Mn.

Manganese can exist in four forms. These forms, called *allotropes,* have different chemical and physical properties. For example, the allotrope *alpha manganese* is brittle and has a density of 7.44 grams per cubic centimeter at 20 °C. Another allotrope, *gamma manganese,* is flexible and has a density of 7.21 grams per cubic centimeter at 20 °C. Manganese metal tarnishes in dry air and rusts in moist air. In dilute inorganic acids, it forms dissolved manganese salts and hydrogen gas.

Sources. Most manganese occurs in iron ores. A high manganese content makes the ore more valuable. China, South Africa, and Ukraine produce the most manganese ore, followed by Brazil and Gabon. The United States, which has few deposits of high-grade manganese ore, imports about three-fourths of its manganese.

The ocean floor, especially in the Pacific, has large deposits of manganese in round masses called *nodules.* The nodules are about 20 percent manganese. They may become an important source of manganese and other metals if the technology for mining them economically is developed.

Manganese ores are processed by several methods. The purest manganese is obtained by heating manganese ores to an extremely high temperature. This *roasting* of the ores produces manganese oxide. Next, mixing this substance with sulfuric acid forms a solution of manganous sulfate. Finally, this solution is purified through *electrolysis*—that is, an electric current is run through the solution to remove the metal from it.

In another method of purification, manganese ore, aluminum, and silicon are deposited in an electric furnace. There, the ore undergoes a chemical process called *reduction* to yield manganese (see **Reduction**).

Emily Jane Rose

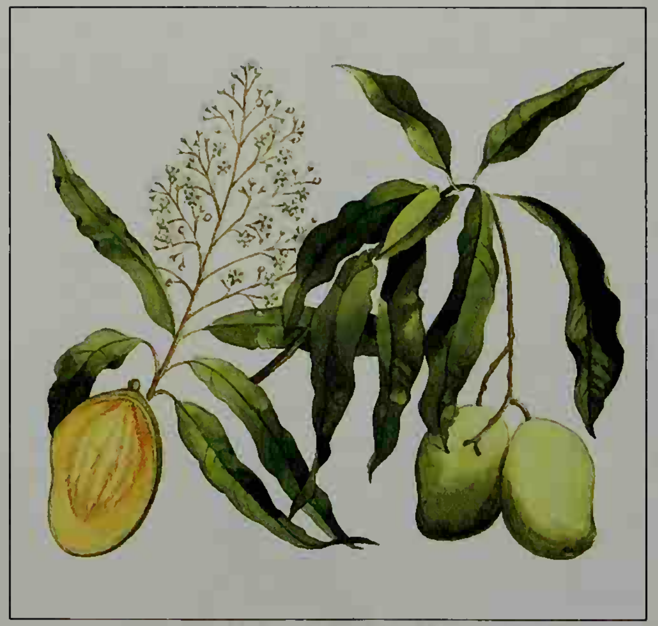
Mange, *maynj,* is a contagious skin disease that certain types of mites cause in dogs, cats, sheep, horses, goats, and swine. Mites usually cause mange in animals that are ill, dirty, or neglected, or that live in crowded conditions. Mange occurs when mites burrow into the skin of animals, causing an irritation. The animals experience severe itching and have areas of redness and swelling. As the disease progresses, the condition of the sores and areas of swelling worsens. Patches of hair or wool

fall out. Continuous scratching may cause open sores.

Veterinarians treat mange chiefly by using antimite sprays or by washing afflicted animals with sulfur or lime-sulfur shampoos. Mange can be prevented by keeping animals' coats clean and well-groomed and by providing the animals with a proper diet; a clean, dry place; and adequate space. Lawrence D. McGill

See also Mite.

Mango is a fruit that grows in tropical regions throughout the world. It serves as the main food of many people in tropical countries and is often called the *king of tropical fruits.* Mangoes are eaten fresh or are used in making desserts, preserves, and some other foods. The fruit is an excellent source of vitamins A and C.



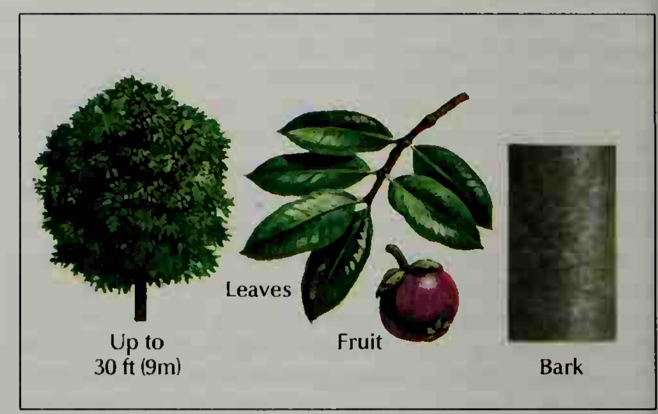
Most mangoes are kidney-shaped, oval, or round. They vary from about 2 to 10 inches (5 to 25 centimeters) in length and from 2 ounces to 5 pounds (57 grams to 2.3 kilograms) in weight. Mangoes have a smooth, leathery skin that surrounds a juicy, yellow or orange pulp and a hard inner pit. The skin may be green, purple, or various shades of orange, red, or yellow. Many mangoes have tough fibers in their pulp, and some of the fruits have an unpleasant turpentinelike odor. But mangoes grown commercially have a soft, fiberless pulp and a sweet, spicy taste and odor.

The mango tree is an evergreen that grows about 70 feet (21 meters) tall. It has long, slender leaves and small, pinkish-white flowers. The fruit develops from the ovaries of the blossoms and ripens about five months after the flowers bloom.

Mangoes were first cultivated about 4,000 years ago in India and the Malay Archipelago. In the 1700's and 1800's, European explorers brought mangoes from India to other tropical countries. Today, farmers grow mangoes in Brazil, India, Mexico, and the Philippines. In the United States, mangoes grow in Florida and in Hawaii.

Philip J. Ito

Scientific classification. The mango belongs to the cashew family, Anacardiaceae. It is *Mangifera indica.*



WORLD BOOK illustration by Kate Lloyd-Jones, Linden Artists Ltd.

Mangoes are delicious tropical fruit. They grow from clusters of tiny pink flowers on the evergreen mango tree.

Mangosteen, *MANG guh steen,* is a tree that grows in Southeast Asia. It is about 30 feet (9 meters) tall. The large, shiny green leaves are thick and leathery. The white to pinkish flowers measure almost 2 inches (5 centimeters) across. The edible fruit is shaped like a tangerine. A hard yellowish to reddish-purple rind surrounds juicy, white flesh that separates into several sections. The fruits are about 2 $\frac{1}{2}$ inches (6 centimeters) across. Cold weather kills the plant. A few mangosteens grow in gardens in the southernmost United States.

Alwyn H. Gentry

WORLD BOOK illustration by John D. Dawson

The mangosteen is a tree from Southeast Asia that produces edible, juicy fruit with a yellowish to reddish-purple rind.

Scientific classification. Mangosteens belong to the garcinia family, Clusiaceae or Guttiferae. They are classified as *Garcinia mangostana.*

Mangrove, *MANG grohv,* is a tree that grows along tropical coasts in salty ocean water. The best-known species is the *red mangrove.* As this type of mangrove develops, it sends down roots from its branches. Eventually, a network of many stiltlike roots supports its leafy crown above the water.

Mangroves form the chief plant growth along long stretches of tropical coasts. They usually grow in places by quiet ocean water. Large mangrove thickets, or forests on stilts, often grow in shallow waters along bays, lagoons, and river mouths. The thousands of stiltlike roots catch silt, which piles up in the water. At the mouths of streams, the roots slow down the current and help settle the silt. Thus, mangroves may aid in building up dry land. The roots also form a breeding place for many fish and other marine life.

Mangrove seeds often germinate while the fruit is on the tree. A seed sends down a root up to 1 foot (30 centimeters) long. When the fruit falls, the heavy root holds it upright as it floats on the water. The root tip eventually strikes mud and a new tree begins to grow.

The red mangrove is found along coasts from Florida to northern South America and in West Africa. Most grow only to the height of a shrub or small tree. Related species can grow up to 82 feet (25 meters) tall. People use the wood of the red mangrove for wharf piles and fuel. The bark is rich in tannic acid, which is used for tanning hides and making dyes. Alwyn H. Gentry

Scientific classification. The mangrove belongs to the mangrove family, Rhizophoraceae. The scientific name for the red mangrove is *Rhizophora mangle.*

Manhattan Island is one of the commercial, financial, publishing, and cultural centers of the world. Millions of people commute there every day to work in offices, factories, shops, and theaters. Manhattan has a population of 1,537,195 and an area of 34 square miles (88 square kilometers), including 12 square miles (31 square kilometers) of inland water. The island forms the smallest, in size, of the five *boroughs* (districts) of New York City. The East River is its eastern border, with Upper New York Bay on the south, the Hudson River on the west, and the Harlem River and Spuyten Duyvil Creek on the north. Bridges, tunnels, and ferries connect the island with the other boroughs and with New Jersey (see **New York City** [map]).

Manhattan Island has many famous landmarks and tourist attractions. They include Broadway, Central Park, Chinatown, the Empire State Building, Greenwich Village, Rockefeller Center, Times Square, the United Nations Headquarters, Wall Street, and many churches, colleges, museums, skyscrapers, and theaters. Most of New York City's municipal buildings stand on the island.

Peter Minuit, governor (or director-general) of the colony of New Netherland, bought Manhattan Island in 1626 from Indians who may have been passing through the area. Minuit paid for the island with beads, cloth, and trinkets worth $24. Michael K. Heiman

See also **Minuit, Peter; New York City** (Manhattan).

Manhattan Project was created by the United States government in 1942 to produce the first atomic bomb. The official agency that produced the bomb was the Corps of Engineers' Manhattan Engineer District, commanded by Major (later Lieutenant) General Leslie R. Groves. The American physicist J. Robert Oppenheimer directed the design and building of the bomb. Industrial and research activities took place at such sites as Los Alamos, New Mexico; Oak Ridge, Tennessee; and Hanford, Washington.

The idea for the project began in 1939, shortly before World War II began. United States scientists feared Germany might be the first country to develop an atomic bomb. They alerted President Franklin D. Roosevelt to this possibility. Manhattan Project scientists successfully exploded the first atomic bomb on July 16, 1945, near Alamogordo, New Mexico. Lucille B. Garmon

See also **Nuclear weapon**.

Mangroves have long, spreading roots that anchor the trees in tropical coastal waters. The roots catch and hold particles of dirt and sand, which helps build up shorelines.

Manic-depressive disorder. See **Bipolar disorder**.

Manichaeism, *MAN uh KEE ihz uhm,* is a philosophical and religious system based on the teachings of a Babylonian prophet named Mani, who lived during the A.D. 200's. According to Manichaeism, two opposing forces govern the universe—the kingdom of light (good) and the kingdom of darkness (evil). The soul, which is a part of the kingdom of light, is trapped inside the body, a part of the kingdom of darkness. The soul yearns to escape the body. This escape can only occur in death, when the soul returns to God.

Manichaeans believed that while living on earth in a mortal body, people must lead lives of self-denial and avoid lusts of the flesh. Only through wisdom can a person hope to avoid the evils of material and sensual things. Wisdom and knowledge will come from a savior who will reveal a plan for salvation and redemption. This savior appears as the prophets Zoroaster, Buddha, and Jesus, and finally as Mani. Manichaeism taught several sacraments necessary for self-denial, such as vegetarianism, simplicity in daily activity, and refraining from sexual intercourse. Robert William Smith

Manifest destiny was a term used to describe the belief in the 1840's in the inevitable territorial expansion of the United States. People who believed in manifest destiny maintained that the United States should rule all North America because of U.S. economic and political superiority, because the U.S. population was growing rapidly, and because it was God's will that the United States should do so. The phrase was first used in 1845 by John L. O'Sullivan in an article on the annexation of Texas. The spirit of manifest destiny was revived at the end of the 1800's, during and after the Spanish-American War (see **Spanish-American War**). See also **United States, History of the** (Expansion). Jerome O. Steffen

Manila (pop. 1,581,082; met. area pop. 9,932,560) is the capital and largest city of the Philippines. It is also the country's leading port and chief cultural, social, educational, and commercial city.

Manila is a place of sharp contrasts, with some people possessing exceptional wealth and others suffering from severe poverty. The city was once known as the *Pearl of the Orient* for its beautiful setting and architectural landmarks. But much of Manila has become crowded and polluted.

Location and size. Manila stretches along the east shore of Manila Bay on the island of Luzon. A crescent of mountains surrounds the city on the north, east, and south. The Pasig River divides the city into two sections. Manila covers a total area of about 15 square miles (38 square kilometers). It is the center of a large metropolitan area that covers 246 square miles (636 square kilometers).

Hutchison Library

Downtown Manila lies on both banks of the muddy Pasig River. The river cuts through the heart of the city and forms an essential part of the harbor on Manila Bay. Several bridges span the river and connect the two parts of the city.

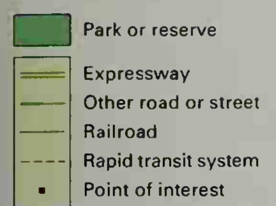
Description. Intramuros, or the Walled City, stands on the south bank of the Pasig River. Spaniards began construction of Intramuros in 1571 and completed it in 1739. They built high walls and a wide moat to protect themselves from attacks by Filipinos. Only the walls and a few of the churches, convents, monasteries, and public buildings still stand. Heavy bombing during World War II (1939-1945) destroyed the rest of Intramuros. Outstanding among the old buildings is San Agustin Church, completed in 1601.

Rizal Park, which is one of Manila's favorite parks, looks across Manila Bay from just outside Intramuros. A statue of José Rizal stands on the spot in the park where this national hero was executed by the Spanish on Dec. 30, 1896. Roxas Boulevard runs south along Manila Bay from Rizal Park. Close to the city center, hotels and mansions line the boulevard, but it also runs through poor areas of the city.

The original business district of Manila lies on the north bank of the Pasig River. Six bridges connect it with the south bank. Chinatown lies on the river's north bank. Many tourists travel to Quiapo, just north of the Pasig, to visit its crowded market and lively restaurants, shopping centers, and movie houses. Thousands of people go to the Quiapo Church every Friday to worship at the shrine of the image of the Black Nazarene. Tondo, in the northwestern corner of the city, is a large poor section. The most modern section of Manila lies in suburban Makati.

Important buildings in Manila include Malacañang—home to many Philippine presidents—and the José Rizal Memorial Stadium. Outstanding government buildings include the Legislative Building, the City Hall, and the Post Office. Bombing during World War II destroyed the Manila Cathedral, originally built in 1654, but it was rebuilt in 1958.

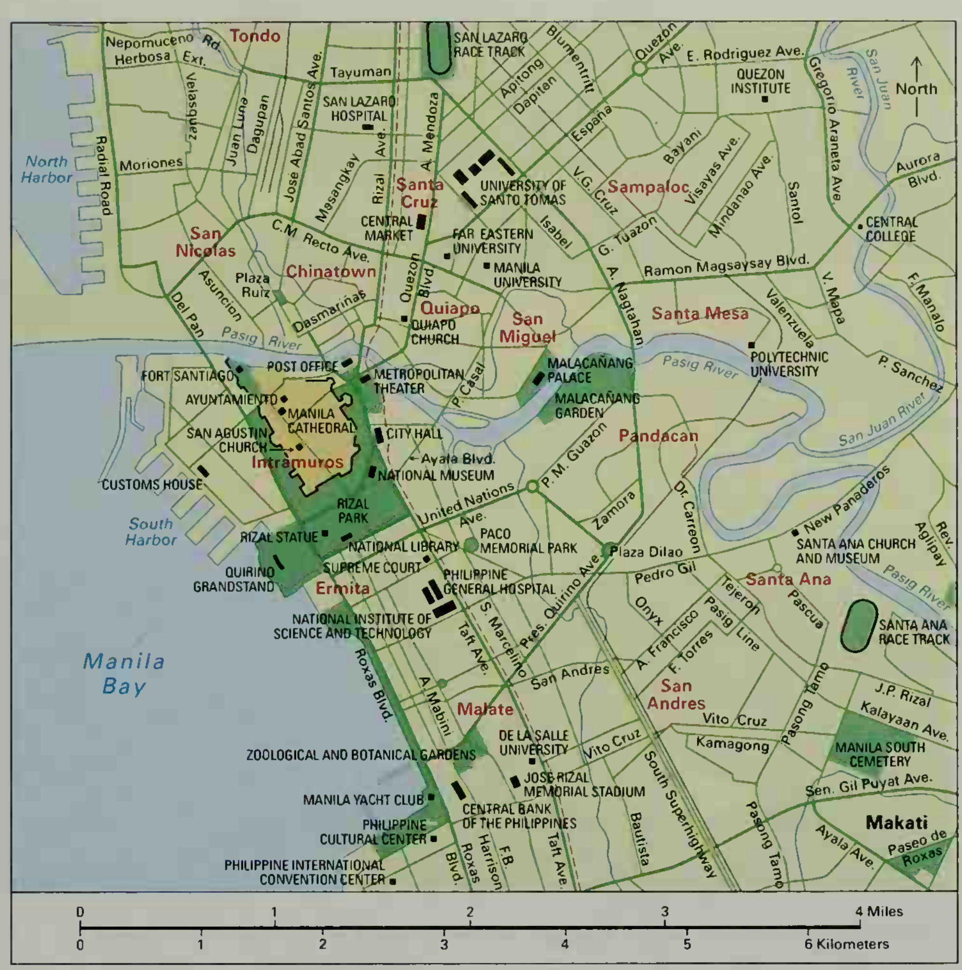
Economy. Manila is the banking, financial, and commercial center of the Philippines. The Asian Development Bank, which lends money to promote economic growth in Asia, has its headquarters in Manila. Industries in Manila turn out a variety of textiles and clothing, and accessory manufacturers produce costume jewelry, hats, leather goods, pearl buttons, and shoes. Handmade items include embroidered goods and furniture. Processing plants produce beer, coconut oil, processed foods, soap, and tobacco products. Other products include building materials, cosmetics, drugs, electronic products, glass, ink, machinery, matches, nails, paints, pencils, radio equipment, and rope and twine.



Manila is an important trade center in the Pacific area. The city's major exports are electronic products, clothing and textiles, and processed foods. Other exports include mineral ores, timber products, and abacá, from which rope is made. Corporations from the United States, Europe, and Japan and other Asian nations have invested in manufacturing operations in Manila. These facilities make electronics, drugs, and processed foods, among other goods.

Transportation and communication. Manila's harbor and location make it an important port on Pacific and Far East trade routes. Piers in the harbor can handle 10 or more large ships at one time. Manila also has an international airport. The Philippine National Railways links Manila with other cities on Luzon. The Manila area also has a small elevated rail rapid transit system.

Manila has many radio and television stations. Publishers in Manila print a number of newspapers and magazines.



Education and cultural life. Manila has several universities. The University of Santo Tomás, the oldest, was founded in 1611. The main campus of the University of the Philippines stands in Quezon City. Many colleges also operate in Manila. The National Museum and Santo Tomás Museum have interesting collections. The city also has a number of public libraries. The Manila Symphony Orchestra plays concert music. Ballet and opera groups are also active in the city.

Government. The Manila metropolitan area is part of the National Capital Region, which is sometimes called

WORLD BOOK maps

Metro-Manila. There are 17 cities and towns within the National Capital Region. Each of the cities and towns has an elected mayor and legislative council. Manila and Quezon City are the largest of the cities.

History. Traders have used Manila and its bay as a port for over a thousand years. In the 1500's, the Manila area was a small sultanate ruled by Rajah Soliman and Rajah Lakandula. The Spanish conquered these rulers, and Miguel López de Legazpi, a conquistador, founded a Spanish city at the site of Manila in 1571.

The Ayuntamiento in Intramuros was built in 1735 to house the city council and the mayor's office. This building became the seat of the national government of the Philippines when the United States took possession of the country. An earthquake destroyed a large part of Manila in 1863.

Spain surrendered Manila to the United States in 1898, during the Spanish-American War. The American administration of the city installed a modern water supply system and electric lighting, and made several other improvements.

Japanese forces seized Manila on Jan. 2, 1942, just four weeks after World War II spread to the Pacific. United States forces began the liberation of the city on Feb. 3, 1945, and a bitter four-week battle followed. Among the first places liberated were the Santo Tomás internment camp and the Bilibid Prison, where the Japanese had kept United States prisoners. Few buildings in Manila remained standing when the Japanese finally surrendered the city on March 4. However, the Filipinos began rebuilding almost immediately afterward.

Manila became the national capital of the Philippines when independence was proclaimed on July 4, 1946. In 1948, the Philippine government made Quezon City the official capital of the country. But Manila continued to serve as the seat of the government, pending the completion of new government buildings in Quezon City. In 1976, the government made Manila the country's official capital again. James Putzel

See also **Philippines** (pictures); **World War II** (The war in Asia and the Pacific).

Manila Bay is the entrance to the city of Manila on Luzon, a northern island in the Philippines. The bay is an extension of the South China Sea. For location, see **Philippines** (map). Manila Bay is about 40 miles (64 kilometers) long and 35 miles (56 kilometers) wide. Its waters are deep enough for large ships. There are two excellent harbors at Cavite and Manila.

The rocky, fortified island of Corregidor is at the mouth of Manila Bay. Some of the most bitter fighting of World War II (1939-1945) took place on Corregidor. The island was attacked by the Japanese during the first days of the war. During the Spanish-American War, in 1898, an American fleet under the command of Commodore George Dewey destroyed a Spanish fleet in a battle at Manila Bay. James Putzel

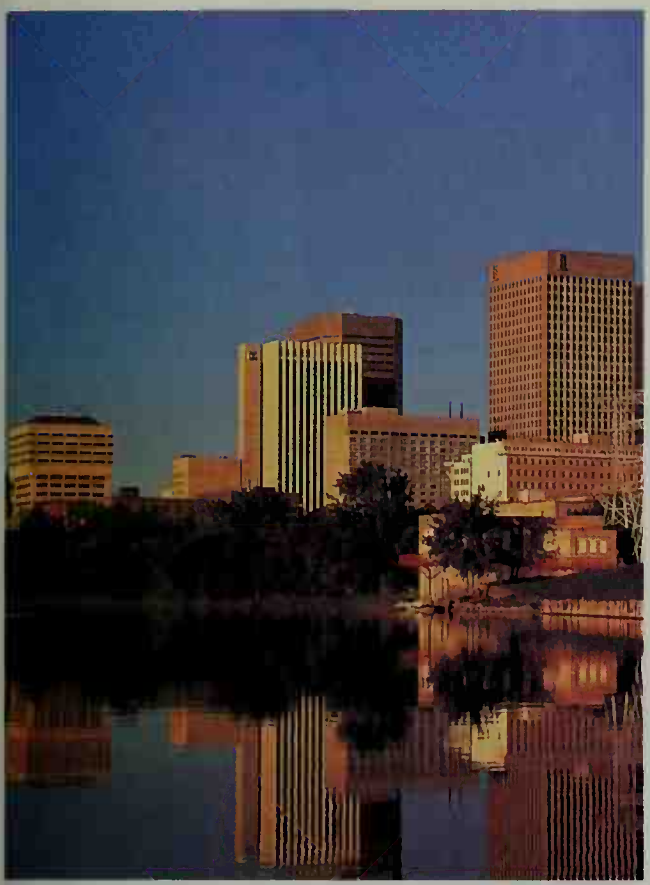
A vast field of Manitoba wheat that spreads out beyond the village of Wellwood

Manitoba

Manitoba, *MAN uh TOH buh,* is one of Canada's three Prairie Provinces. The other two are Alberta and Saskatchewan. Manitoba lies midway between the Atlantic and Pacific oceans. Winnipeg, Manitoba's capital and largest city, is the main transportation center linking eastern and western Canada.

More than half the people of Manitoba live in the Winnipeg metropolitan area. Winnipeg is the province's major industrial center. Busy food-processing plants and other factories are located in Winnipeg, which also serves as a major distribution center. In addition, the Winnipeg metropolitan area has clothing factories and plants that manufacture transportation equipment and electronic products.

Winnipeg lies in the plains that cover part of southern Manitoba. This fertile region has the richest farmlands in the province. In summer, vast fields of wheat and other grains wave in the sun. Large numbers of beef cattle graze in fenced pastures. Other important farm products of this southern region include canola, hogs, milk, oats, and potatoes.



The contributors of this article are John S. Brierley, Professor of Geography at the University of Manitoba; and J. M. Bumsted, Professor of History at St. John's College, University of Manitoba.

A vast, rocky region lies across the northern two-thirds of Manitoba. This thinly populated region has great deposits of copper, nickel, and zinc. Thompson has one of the few facilities in the Western world for all stages of nickel production, from mining to processing. This thriving town was carved out of the wilderness after prospectors discovered vast deposits of nickel in the area. Manitoba supplies about one-fourth of the nickel that is produced in Canada. The province ranks among the leading North American producers of nickel and zinc.

Thick forests stretch across the southern half of the region. Balsam fir, spruce, and other trees that grow in this area provide wood for Manitoba's furniture factories and paper mills.

Manitoba's many rivers and lakes cover almost a sixth of the province and help make it a popular vacationland. Tourists enjoy boating and swimming in the clear, sparkling waters. Fishing enthusiasts come from many parts of North America to cast for bass, catfish, pike, and trout. In the rugged forests of Manitoba, hunters track black bear, caribou, elk, moose, and smaller game. In the province's marshes and prairies, hunters shoot ducks, geese, and sharp-tailed and ruffed grouse.

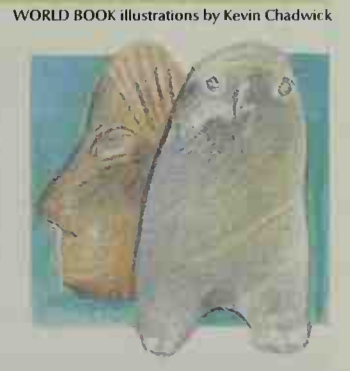
Beaver and other fur-bearing animals made the Manitoba region important during the late 1600's. English fur

Stuart McCall, Northlight

Winnipeg, the capital of Manitoba

traders entered the rich fur country from Hudson Bay in the northeast. French-Canadian traders came westward from Quebec during the early 1700's. The adventurous fur traders paddled their birchbark canoes up Manitoba's rivers and traveled through forests and plains. They traded with the Indians of the region and built forts and trading posts in the wilderness. Irish and Scottish farmers began breaking up the plains of Manitoba in the early 1800's. Vast wheat fields were created in the fertile Red River Valley. Manitoba began exporting wheat, and the grain it produced became famous for its high quality.

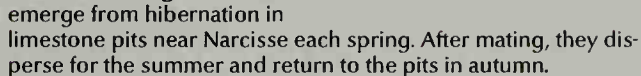
The word *Manitoba* probably came from the Algonquian language of the Indians. The tribes thought the *manito* (great spirit) made the echoing sounds that came from a strait of Lake Manitoba. These sounds were actually made by waves dashing against limestone ledges on the shore. The Indians called this part of the lake *Manito waba* (great spirit's strait).



Manitoba's nickname is the *Keystone Province.* It earned this nickname because of its location in the central, or keystone, position of the "arch" formed by the 10 Canadian provinces.

For the relationship of Manitoba to the other Canadian provinces, see the *World Book* articles on **Canada; Canada, Government of; Canada, History of.**

Interesting facts about Manitoba



WORLD BOOK illustrations by Kevin Chadwick

Two of the world's best collections of Inuit (Eskimo) art are located in Manitoba. One is at the Eskimo Museum in Churchill, which is devoted entirely to Inuit art. The other, housed at the Winnipeg Art Gallery, contains about 6,000 examples.

Inuit art

Manitoba's seaport, at Churchill, is the only seaport in the Prairie Provinces.

Thousands of garter snakes emerge from hibernation in limestone pits near Narcisse each spring. After mating, they disperse for the summer and return to the pits in autumn.

One of the world's largest denning areas for polar bears lies south of Churchill. The town, sometimes called the *Polar Bear Capital of the World,* is the most accessible and habitable area in the world lying within reach of an area where polar bears live. Each fall, polar bears converge on Churchill, waiting for ice to form on Hudson Bay so they can hunt for seals. Polar bears often wander close to town, where they search for food in garbage dumps.

Polar bears

Copper and zinc mining near Lynn Lake

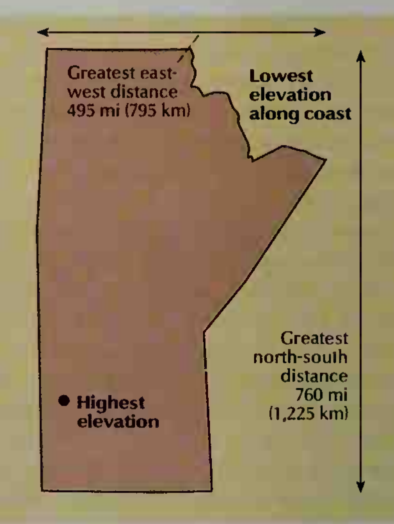
Manitoba in brief

Symbols of Manitoba

The provincial flag, adopted in 1966, bears the British Union Flag and a shield. The buffalo symbolizes that animal's importance in Manitoba's early history. The red cross of St. George represents Manitoba's bond with the United Kingdom. Manitoba's coat of arms, adopted in 1992, shows a unicorn from the British coat of arms. The horse symbolizes Manitoba's early history. The beaver, Canada's national animal, represents Manitoba's historic fur trade.

Provincial flag

Manitoba (brown) is the sixth largest province in Canada and the smallest of the Prairie Provinces (yellow).



The Manitoba Legislative Building is in Winnipeg, the province's capital since it entered the Dominion in 1870.

General information

Entered the Dominion: July 15, 1870, the fifth province.
Provincial abbreviation: MB (postal).
Provincial motto: *Gloriosus et Liber* (Glorious and Free).

Land and climate

Area: 250,947 mi² (649,950 km²), including 39,224 mi² (101,590 km²) of inland water.
Elevation: *Highest*—Baldy Mountain, 2,727 ft (831 m) above sea level. *Lowest*—sea level, along Hudson Bay.
Coastline: 400 mi (645 km).
Record high temperature: 112 °F (44 °C) at St. Albans, near Wawanesa, on July 11, 1936, and at Emerson on July 12, 1936.
Record low temperature: −63 °F (−53 °C) at Norway House on Jan. 9, 1899.
Average July temperature: 66 °F (19 °C).
Average January temperature: −4 °F (−20 °C).
Average yearly precipitation: 20 in (50 cm).

Important dates

- **1612** Sir Thomas Button of England explored the west coast of Hudson Bay.
- **1738** Pierre Gaultier de Varennes, Sieur de la Vérendrye, built Fort Rouge at the site of present-day Winnipeg.
- **1812** Settlers sent by the Earl of Selkirk established the Red River Colony.
- **1869-1870** Louis Riel led métis in the Red River Rebellion.

Sources of information

For information on tourism in Manitoba, write to: Travel Manitoba, Department RC2, 7-155 Carlton Street, Winnipeg, MB R3C 3H8. Travel Manitoba's Web site at www.travelmanitoba.com also provides tourist information. For information on the province's economy and government, write to: Manitoba Information Services, Room 29, Legislative Building, Winnipeg, MB R3C 0V8. For information on Manitoba's history, write to: Manitoba Culture, Heritage and Tourism, Main floor, 213 Notre Dame Avenue, Winnipeg, MB R3B 1N3. The department's Web site at www.gov.mb.ca/chc/ is also a useful resource.

1870 Manitoba became Canada's fifth province on July 15.

1912 The Canadian government extended Manitoba's northern boundary to Hudson Bay.

1960 Nickel mining operations began in Thompson.

1972 Winnipeg and its suburbs merged into one city, making Winnipeg one of Canada's largest cities.

People

Bill Brooks, Masterfile

Winnipeg's Old Market Square lies in a restored historic area of the city. Many people visit the square during the summer to enjoy its outdoor flea market and live entertainment.

Population. The 2001 Canadian census reported that Manitoba had 1,119,583 people. The population of the province had increased by less than 1 percent over the 1996 figure of 1,113,898.

About three-fourths of the people of Manitoba live in cities and towns. About three-fifths live in the metropolitan area of Winnipeg. Winnipeg is the largest city and chief industrial center. It has the province's only Census Metropolitan Area as defined by Statistics Canada.

Brandon is the next largest city in Manitoba, followed by Thompson and Portage la Prairie. For more information, see the articles on the cities and towns of Manitoba listed in the *Related articles* at the end of this article.

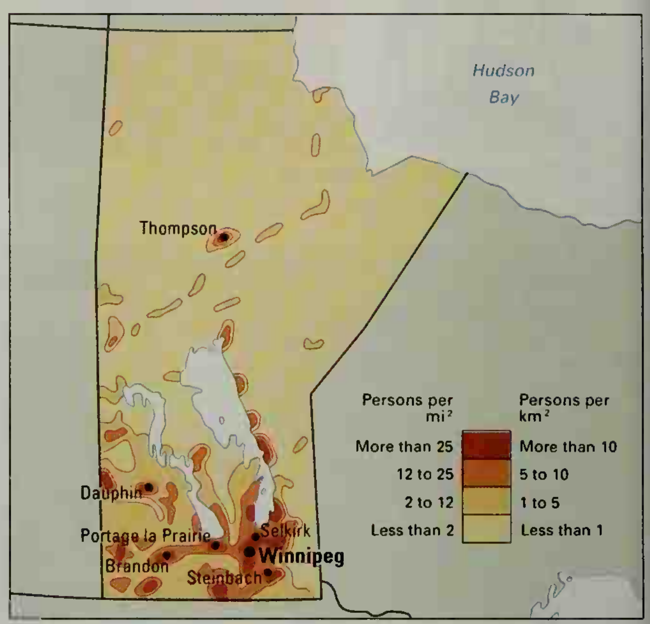
About 85 out of 100 Manitobans were born in Canada. About half of the people in Manitoba have some British ancestry. Other large ethnic groups, in order of size, include Germans, Ukrainians, and French. Winnipeg's St. Boniface district is the center of French-Canadian culture in the province. Of the people born outside of Canada, many come from Asian and Caribbean countries.

Manitoba has about 46,000 *métis* (persons of mixed white and Indian ancestry). There are about 56,000 North American Indians and about 700 Inuit. Another 21,000 people have some American Indian ancestry. Manitoba has more than a hundred Indian reservations. Most of the Inuit live near Churchill.

Schools. The first school in the Manitoba region was set up by the first European settlers to the Red River Colony, in 1812. In 1818, Roman Catholic missionaries, led by Joseph Provencher, began setting up schools along with churches. John West, an Anglican missionary, opened the Manitoba region's first Protestant school in 1820.

In 1871, a church-supported educational system, which had developed, was ended. The province created a board of education to direct the schools and provide them with public funds. Roman Catholic board members managed the Roman Catholic schools, and Protestant members supervised the Protestant schools. In 1890, the province abolished the board of education and its double school system. The provincial Department of Education was created to head a single education system. In 1908, the cabinet office of minister of education was established in Manitoba.

Today, Manitoba's Department of Education, Training and Youth oversees public education from kindergarten through high school. The Department of Advanced Education handles issues affecting universities and colleges.



Manitoba law requires all children from the ages of 7 to 16 to attend school. For information on the number of students and teachers in Manitoba, see **Education** (table).

Libraries and museums. The largest libraries in the province are all in Winnipeg. They include Centennial Library (a public library), the Legislative Library, the Provincial Archives, and the University of Manitoba Library.

The Hudson's Bay Company Archives in Winnipeg contain materials on the human and natural history of northwestern North America. The Museum of Man and Nature and the Winnipeg Art Gallery, both in Winnipeg, attract many visitors each year.

Population density

About three-fifths of Manitoba's people live in and around Winnipeg, the province's largest city. The northern areas are thinly populated, partly because they have a severe climate.

WORLD BOOK map; based on the *National Atlas of Canada*.

Universities and colleges

Manitoba has four degree-granting universities and colleges that are members of the Association of Universities and Colleges of Canada, listed below.

Name	Mailing address
Brandon University	Brandon

Visitor's guide

Manitoba features beautiful white-sand beaches, shimmering lakes, rugged rivers, and vast stretches of untouched wilderness. The province's streams are full of sport fish. In northern areas, people can watch polar bears and view the dramatic natural light displays known as the *aurora borealis* or the *northern lights.* Lake Winnipeg and many other lakes in Manitoba have summer resorts that offer boating and swimming.

Visitors to Manitoba can see many reminders of the province's colorful history. Forts and trading posts of the early fur-trading days are popular. The beautiful St. Boniface Cathedral, in Winnipeg, stands on the site of the first Roman Catholic church in western Canada. Many people who helped shape the history of Manitoba are buried in the churchyard, including the métis leader Louis Riel.

Many visitors to the province attend performances of the Royal Winnipeg Ballet, the Winnipeg Symphony Orchestra, and other groups. Sports fans visit Winnipeg to see the Blue Bombers of the Canadian Football League.

Manitoba's annual events include many colorful festivals. The Winnipeg Folk Festival, featuring folk musicians and singers, is held in Birds Hill Park each July. The National Ukrainian Festival occurs each July in Dauphin.

Places to visit

Following are brief descriptions of some of Manitoba's many interesting places to visit:

Centennial Centre, in Winnipeg, includes the Manitoba Museum of Man and Nature, a concert hall, and a planetarium.

Churchill, a seaport town on the rocky coast of Hudson Bay, is known as the Polar Bear Capital of the World. People can watch polar bears and beluga whales in their native habitats and can view the northern lights. The partially restored Fort Prince of Wales, built by the Hudson's Bay Company in the 1700's, overlooks the bay near Churchill. The area also has museums featuring Inuit arts and artifacts.

International Peace Garden lies partly in Manitoba and partly in North Dakota. This nonprofit botanical garden and park is dedicated to the long-standing peace between Canada and the United States.

Lower Fort Garry, 20 miles (32 kilometers) north of Winnipeg, is the only stone fur-trading fort in Canada still standing complete. It was built in the 1830's by the Hudson's Bay Company on the Red River. The area is now a national historic park.

Mennonite Heritage Village, in Steinbach, is a reproduction of an authentic Mennonite village. It includes a blacksmith shop, a general store, farmhouses, a livery barn, and a sod house. A huge windmill towers over the site.

Oak Hammock Marsh, near Stonewall, is one of North America's best areas for bird watching. Visitors can see over 260 kinds of birds in this 8,650-acre (3,500-hectare) habitat.

Spirit Sands, in Spruce Woods Provincial Park, features high sand dunes and plants and animals that are rare to Manitoba.

National and provincial parks. Riding Mountain National Park lies west of Lake Manitoba. For its area and chief features, see Canada (National parks and national park reserves). Manitoba has 12 provincial parks. For information on the parks, write to Conservation Manitoba, Parks and Natural Areas, 200 Saulteaux Crescent, Winnipeg, MB R3J 3W3. Conservation Manitoba's Web site at www.manitobaparks.com provides detailed information about Manitoba's provincial parks.

Land and climate

Land regions. Manitoba has four main land regions. They are, from northeast to southwest: (1) the Hudson Bay Lowland, (2) the Canadian Shield, (3) the Manitoba Lowland, and (4) the Saskatchewan Plain.

The Hudson Bay Lowland is a wet plain bordering the southern part of Hudson Bay. In Manitoba, this almost treeless flatland extends about 100 miles (160 kilometers) into the interior. Few people live there.

The Canadian Shield is a vast, horseshoe-shaped region that covers almost half of Canada and part of the United States. The rough shield, made up mostly of granites and other kinds of rocks, covers nearly two-thirds of Manitoba. It has many lakes, streams, and forests, and deposits of copper, nickel, and other minerals. See **Canadian Shield**.

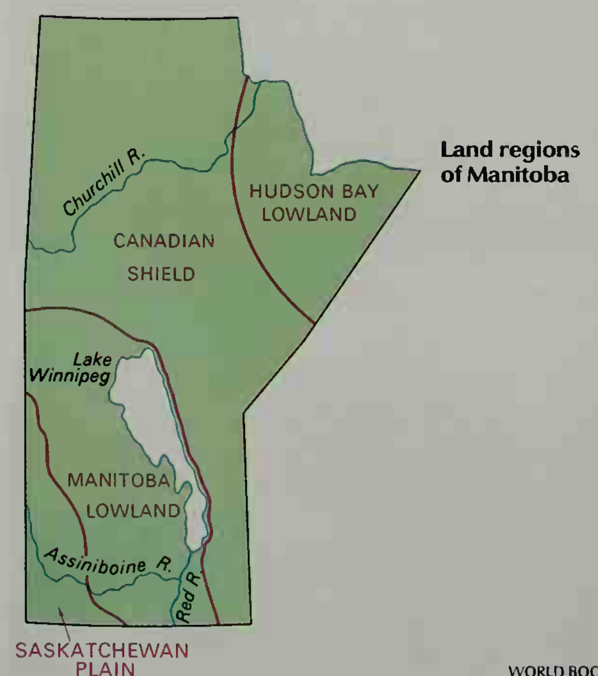
The Manitoba Lowland forms part of the Western Interior Plains, the Canadian section of the North American Great Plains. It is a flat area of forests, lakes, limestone rock, prairie, and swamps. The forests have great stands of timber, and the lakes are rich in fish.

The Saskatchewan Plain also forms part of the Western Interior Plains. This region is a rolling plain broken by low hills. Its rich, well-drained soils make it the main farming region of Manitoba.

Coastline. Manitoba has 400 miles (645 kilometers) of coastline along Hudson Bay in the northeastern part of the province. Few inlets or islands lie along the coast.

T. Klassen, Hot Shots

A polar bear roams in the Hudson Bay Lowland, a flat, treeless region that extends about 100 miles (160 kilometers) inland from Hudson Bay. Few people live in this region.



Hudson Bay waters are frozen much of the year, and so commercial shipping activities are limited in the coastal region.

Mountains. The Duck, Porcupine, and Riding mountain ranges form the Manitoba Escarpment. It rises between the two plains regions. The highest point in Manitoba is 2,727-foot (831-meter) Baldy Mountain, in the Duck Mountain range near the Saskatchewan border. The Turtle and Pembina hills of North Dakota extend into the southern part of Manitoba.

Rivers and lakes cover almost a sixth of Manitoba, or 39,225 square miles (101,592 square kilometers). The rivers form a great waterway system that drains western Canada from as far west as the Rocky Mountains. The Red, Saskatchewan, and Winnipeg rivers flow into Lake Winnipeg. Important branches of the Red River are the Assiniboine and Pembina rivers. The Nelson River flows out of Lake Winnipeg across the Canadian Shield, and empties into Hudson Bay. The Churchill and Hayes rivers also drain northern Manitoba.

Manitoba has about 100,000 lakes. Three lakes are so large that they are often called the *Great Lakes of Manitoba*. Lake Winnipeg, which covers 9,416 square miles (24,387 square kilometers), is the largest body of water entirely within any province or state. Lake Winnipegosis covers 2,075 square miles (5,374 square kilometers), and Lake Manitoba spreads over 1,785 square miles (4,624 square kilometers). Other lakes include Dauphin, Gods, Island, Reindeer, Southern Indian, and Tadoule.

Plant and animal life. Manitoba has about 97,000 square miles (251,000 square kilometers) of forests. The

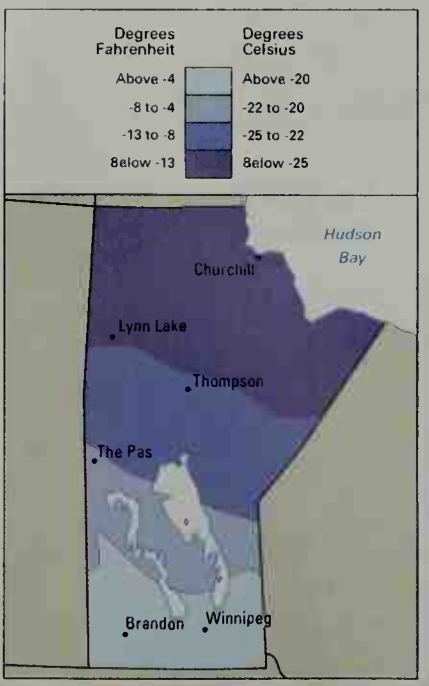
Manitoba Department of Industry, Trade, and Tourism

Forests and lakes are abundant in the rocky region called the Canadian Shield, which covers almost two-thirds of Manitoba.

most common trees are the aspen, black spruce, jack pine, and white spruce. Others include ash, birch, maple, oak, and tamarack. Columbines, fireweeds, and other wild flowers grow in many parts of the province.

Caribou, elk, and moose live in the northern forests. Deer thrive there and in most parts of southern Manitoba. Fur-bearing animals of the forests include the beaver, fox, lynx, mink, and muskrat. Other animals include the bear, coyote, ermine, otter, and raccoon. Ducks and geese fly north in spring to breed in Manitoba's lakes and ponds. Grouse, prairie chickens, ptarmigan, and other game birds live in Manitoba. Fish there include bass, goldeye, perch, pickerel, pike, sauger, sturgeon, trout, tullibee, and whitefish.



Climate. Manitoba has long, bitterly cold winters and warm summers. In general, the temperature decreases from the southwestern part of the province to the northeastern section. The average January temperature is 0°F (−18 °C) in the south and −17 °F (−27 °C) in the north. The lowest recorded temperature, −63 °F (−53 °C), occurred in Norway House on Jan. 9, 1899. Average July temperatures range from 68 °F (20 °C) in the south to 55 °F (13 °C) in the north. The highest temperature was 112 °F (44 °C), recorded in St. Albans near Wawanesa, on July 11, 1936, and in Emerson on July 12, 1936. Manitoba's *precipitation* (rain, melted snow, and other forms of moisture) averages 20 inches (50 centimeters) a year. About 50 inches (130 centimeters) of snow falls a year.

Average January temperatures

Manitoba has long, cold winters. The province's temperatures decrease steadily from the far south to the north.

Average July temperatures

The province has mild summers. The southern section of Manitoba has the highest summertime temperatures.

Average yearly precipitation

The southeastern portion of Manitoba has the greatest amount of precipitation. The far north is the driest area.

WORLD BOOK maps, based on the *National Atlas of Canada.*

For many years, the economy of Manitoba was based chiefly on agriculture. Many new industries developed in the 1940's, and manufacturing increased rapidly. Today, service industries, taken together, make up the largest part of Manitoba's *gross domestic product* (GDP)—the total value of all goods and services produced. Manufacturing industries, which include construction, manufacturing, mining, and utilities, rank second.

Natural resources. Manitoba's chief natural resources include fertile soils and rich mineral deposits. The forests and wildlife of Manitoba are also important to the province's economy.

Soil. The deep, fertile soils of the southern plains are perhaps the province's chief natural resource. Some of these soils were deposited by glaciers or by ancient glacial lakes. The soils of southern Manitoba vary from clays to loams and bog. The soils of the Hudson Bay Lowland contain clay.

Minerals. The Canadian Shield region of Manitoba has large deposits of copper, lithium, nickel, zinc, and other minerals. Deposits of gypsum lie just north of Lake Manitoba. Southwestern Manitoba's minerals include bentonite, limestone, petroleum, and potash.

Service industries provide the largest portion of Manitoba's gross domestic product. Service industries are concentrated in Winnipeg.

Community, business, and personal services form the leading service industry group in Manitoba. This group includes such activities as education, health care, legal services, and the operation of hotels and repair shops. Community, business, and personal services employ more than a third of the province's workers.

Finance, insurance, and real estate rank second among Manitoba service industry groups in terms of the gross domestic product. Real estate is an important part of this industry because of the large sums of money involved in the selling and leasing of homes, office space, and other property. Many of Canada's largest financial companies have major branch offices in Winnipeg.

Ranking next among the service industries of Manitoba are wholesale and retail trade. Wholesale companies buy goods from producers and sell the goods mainly to other businesses. The wholesale trade of livestock, grains, and food products is a major part of the province's economy. Retail businesses sell goods directly to the public. Common types of retail establishments are automobile dealerships, food stores, and department stores.

Transportation and communication rank fourth. Railroads and trucking firms make up the most important part of the transportation and communication sector in Manitoba. The province's telephone company is the leading communication business. More information on transportation and communication appears later in this section. Other service industries include government services. Most government activities are centered in Winnipeg.

Manufacturing. Goods manufactured in Manitoba have a *value added by manufacture* of about 4 $\frac{1}{2}$ billion Canadian dollars yearly. This figure represents the difference between the value of raw materials and the value of the finished products made from the raw materials.

Food and beverage processing is Manitoba's major manufacturing activity. Leading food-processing establishments produce meat products, frozen potato products, dairy products, bakery goods, and soft drinks.

Transportation equipment ranks second among Manitoba's products in value added by manufacture. Winnipeg is a leading Canadian producer of aerospace equipment and buses.

Other products made in Manitoba include clothing, electronic equipment, fabricated metal products, machinery, primary metals, and printed materials. These items are produced mainly in Winnipeg. Women's sportswear is the leading type of clothing made in the province. Computer parts and telecommunications equipment are the leading types of electronic equipment. Machine tools and structural metal are among Manitoba's fabricated metal products. Agricultural equipment is the leading type of machinery. A nickel smelter in Thompson and a copper and zinc smelter in Flin Flon produce primary metals. Newspaper companies and print shops turn out most of the printed materials in the province.

Agriculture provides the economic base for most rural communities in southern Manitoba. The province has about 24,000 farms. Farmland covers about 14 percent of Manitoba's land area.

Wheat and canola rank as Manitoba's most valuable farm products. Wheat farmers primarily raise varieties of hard red spring wheat. Potatoes and oats rank next in value. Potatoes are grown in the southern and western parts of the province. Wheat and oat production is heaviest southwest of Winnipeg. Canola, flaxseed, and sunflowers are grown for their oil. Other important field crops raised in Manitoba include alfalfa, barley, dry beans, peas, and rye. Vegetable farms lie near Portage la Prairie and Winkler.

Together, the raising of beef cattle and of hogs provide about a third of the value of the province's farm

Production and workers by economic activities

Economic activities	Percent of GDP* produced	Employed workers: Number of people	Employed workers: Percent of total

output. Dairy farming is most important in south-central Manitoba. Chickens and eggs are also important farm products in the province.

Mining. Nickel production accounts for nearly half of Manitoba's mining income. Ontario is the only region in North or South America that produces more nickel than Manitoba. Thompson is the chief center of nickel production in Manitoba. Nickel also comes from mines near Wabowden and Lynn Lake.

Manitoba's other leading mined products include copper, petroleum, and zinc. Copper is obtained as a by-product of nickel mining. It also occurs along with zinc. Large copper-zinc mines operate near Flin Flon, Leaf Rapids, Lynn Lake, and Snow Lake. All of the petroleum mined in Manitoba comes from the southwestern part of the province. Oil production is heaviest in the Daly, Virden, and Waskada areas. Other mined products include cobalt, gold, limestone, lithium, platinum, sand and gravel, silver, and tantalum.

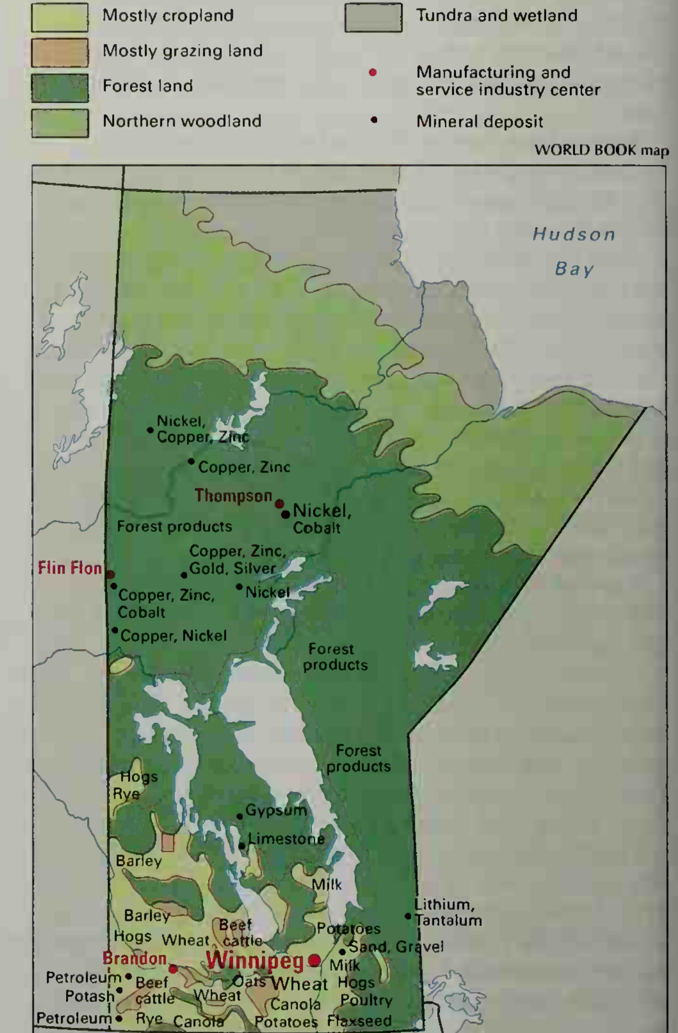
Electric power and utilities. Hydroelectric power plants generate most of the province's electric power. Plants on the Laurie, Nelson, Saskatchewan, and Winnipeg rivers supply power to Manitoba, nearby provinces, and parts of the United States. The major source of electric power is the lower Nelson River. Manitoba's largest station, at Limestone Rapids, began full operation in 1992. Other utilities in Manitoba provide gas and water service.

Transportation. Major airlines offer flights from Winnipeg to large cities in other provinces. Smaller airlines connect Winnipeg to Brandon, The Pas, Thompson, Churchill, and other communities in Manitoba.

Manitoba's main rail lines branch out from Winnipeg to the east and to the west. Brandon and Portage la Prairie are also important rail centers. The main rail line in northern Manitoba connects The Pas, Thompson, and Churchill.

Most of Manitoba's roads are in the southern part of the province. The Trans-Canada Highway crosses Manitoba through Winnipeg and Brandon and serves as the major east-west thoroughfare. Other major roads link Flin Flon and Winnipeg with North Dakota, and Winnipeg with Thompson. In winter, bulldozers pack the snow to make roads in northern Manitoba.

Churchill, on Hudson Bay, is Manitoba's only seaport.



Freeman Patterson, Masterfile

Cattle graze on a pasture in southern Manitoba. Raising beef cattle is one of the province's most valuable agricultural activities. Farmers in Manitoba also raise dairy cattle and hogs.

Economy of Manitoba

This map shows the economic uses of land in Manitoba and where the province's leading farm, mineral, and forest products are produced. Major manufacturing centers are shown in red.

It is blocked by ice during winter and spring. Shipping from the port occurs only during the months of August, September, and October. Trains carry wheat to Churchill for export to the United Kingdom and other European countries. Manitoba's most important inland waterways are Lake Winnipeg and the Red River.

Communication. The first newspaper published in Manitoba, *The Nor' Wester,* was issued in 1859 in Fort Garry (now Winnipeg). Today, the province has five daily newspapers, the largest of which is the *Free Press* of Winnipeg. About 50 weekly newspapers are also published in the province. *The Lance,* printed in Winnipeg, has the largest circulation of these weekly papers. A French-language weekly, *La Liberté,* is published in the St. Boniface district of Winnipeg.

The first radio station in Manitoba, CKY, began broadcasting from Winnipeg in 1922. The first television station, CBWT, began operating in Winnipeg in 1954. Two French-language radio stations broadcast from the St. Boniface area. Manitoba has about 30 radio stations and 15 TV stations. Cable television systems and Internet providers serve many Manitoba communities.

Travel Manitoba

Manitoba's Legislative Assembly is a one-house legislature. Its 57 members serve terms of up to five years.

Lieutenant governor of Manitoba represents the British monarch, Queen Elizabeth II, in her role as the queen of Canada. The lieutenant governor is appointed by the governor general in council of Canada. The position of lieutenant governor is largely ceremonial.

Premier of Manitoba is the actual head of the provincial government. The province, like the other provinces and Canada itself, has a *parliamentary* form of government. The premier is an elected member of the Legislative Assembly. The person who serves as premier leads the majority party in the Assembly. The premier presides over the Executive Council (cabinet). The cabinet also includes ministers chosen by the premier from among party members in the Legislative Assembly. Each minister directs one or more departments of the provincial government. The cabinet, like the premier, resigns if it loses the support of a majority of the Assembly.

Legislative Assembly is a one-house legislature that makes the provincial laws. It has 57 members elected from 57 electoral districts. The members serve terms that may last up to five years. However, the lieutenant governor, on the advice of the premier, normally calls an election before the end of the five-year period.

Courts. The highest court in Manitoba is the Court of Appeal. It is made up of the chief justice of Manitoba and six judges of appeal. The Court of Queen's Bench is the highest trial court in Manitoba and has authority to hear civil and criminal cases, including those that involve jury trials. The court consists of a chief justice, two associate chief justices, and 31 other judges. Eleven of the judges serve the family division of the court. Manitoba's Provincial Court deals mostly with criminal cases that do not involve jury trials. They also hear child-protection and certain other family cases.

The governor general in council appoints the judges of the Court of Appeal and the Court of Queen's Bench. They serve until age 75. Provincial Court judges are appointed by Manitoba's lieutenant governor in council and may serve until any age. Provincial authorities appoint other judicial officers, including magistrates or justices of the peace.

Local government. Manitoba has about 200 incorporated cities, towns, villages, and rural municipalities. Each is governed by a council headed by a mayor or a reeve. The number of council members ranges from 4 to 10. The mayor or reeve and the council members are elected to four-year terms. The province also has 17 local government districts in remote or thinly settled areas. These districts are governed by resident administrators, appointed by the provincial government.

Winnipeg, Manitoba's capital, is incorporated and governed by the City of Winnipeg Act. The province's other communities—including cities, towns, villages, and rural municipalities—are incorporated and governed by the Municipal Act. Some of the cities also have special charters, which may give them additional authority. Manitoba's Department of Intergovernmental Affairs has responsibility for all municipalities in the province.

Revenue. The provincial government of Manitoba gets about 55 percent of its *general revenue* (income) from taxation. Most of this money comes from taxes on personal income and retail sales. Other taxes include those levied on corporate incomes and sales of gasoline and tobacco. Such financial agreements as national and provincial tax-sharing arrangements account for about 35 percent of Manitoba's revenue. Additional revenue is received from license fees and from the sale of liquor, which is controlled by the provincial government.

Politics. The major political parties of Manitoba are the Progressive Conservative Party, the New Democratic Party, and the Liberal Party. The Progressive Conservative Party was formerly named the Conservative Party, and today members are usually simply called Conservatives. The New Democratic Party is a democratic socialist party. It was formerly called the Co-operative Commonwealth Federation. In 1932, the Liberals joined the provincial government headed by a farmers' organization called the Progressives. They were called the Liberal Progressives until 1961. A Manitoba citizen must be at least 18 years old to vote in an election.

The premiers of Manitoba

	Party	Term
Alfred Boyd	None	1870-1871
Marc A. Girard	Conservative	1871-1872
Henry J. H. Clarke	None	1872-1874

Edward R. Schreyer	New Democratic	1969-1977
Sterling R. Lyon	Progressive Conservative	1977-1981
Howard R. Pawley	New Democratic	1981-1988
Gary Filmon	Progressive Conservative	1988-1999
Gary Doer	New Democratic	1999-

History

Indian days. Five Indian tribes lived in the Manitoba region when the first explorers and fur traders arrived. The Chipewyan Indians hunted caribou across the northern section. The Woods Cree, who hunted beaver and moose, lived in the central forests. The Plains Cree fished and trapped animals in the prairies and wooded lowlands. The Assiniboine lived on the southwestern plains. These allies of the Cree were buffalo hunters. The Chippewa, who also hunted buffalo, lived in the southeastern section of the plains.

Exploration. The English explorer Sir Thomas Button and his crew were the first white people in the Manitoba region. They sailed down the west coast of Hudson Bay in 1612. Button and his crew spent the winter at the mouth of the Nelson River, and claimed the land for England. Two English seamen, Luke Foxe and Thomas James, explored Hudson Bay and its west coast in 1631.

In 1670, King Charles II of England granted trading rights in the region to the Hudson's Bay Company of London. The region was called Rupert's Land. By 1690, English fur traders had fought many battles with their French-Canadian rivals, who were pushing westward into the Hudson Bay region. The company sent Henry Kelsey on an expedition to find new sources of fur. Kelsey left the company's outpost in York Factory and traveled among the Indians of central and southern Manitoba from 1690 to 1692. He persuaded many of them to bring furs north to the company trading posts. See **Hudson's Bay Company**.

In 1731, Pierre Gaultier de Varennes, Sieur de La Vérendrye, left Montreal in search of an overland route to the Pacific Ocean. He and his men were French-Canadian fur traders. They built a series of forts between the Lake Superior area and the lower Saskatchewan River. These outposts included Fort Rouge, which La Vérendrye built on the site of present-day Winnipeg in 1738. The fur trade that he established cut heavily into that of the Hudson's Bay Company.

In 1763, the British defeated the French in the French and Indian War, also known as the Seven Years' War. France gave up its Canadian lands to Britain, and French exploration and trade in the Manitoba region stopped. In the 1770's, the North West Company was first established in Montreal to compete with the Hudson's Bay Company. The new firm soon disbanded. A new agreement drafted in 1784 reestablished the firm and officially adopted the name North West Company. See **North West Company**.

Illustration (1888) by Frederic Remington; Glenbow Archives

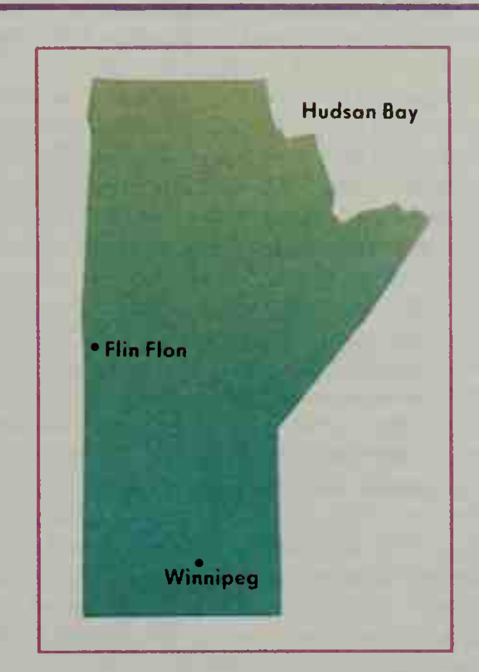
Fur-trappers of the North West Company competed for land with farmers of the Red River Colony during the early 1800's. Several skirmishes took place, but peace was restored by 1821.

The Red River Colony. While the two fur companies competed for trade, plans were made for the Manitoba region's first agricultural settlement. In 1811, Thomas Douglas, fifth Earl of Selkirk, obtained a land grant from the Hudson's Bay Company. It consisted of more than 100,000 square miles (260,000 square kilometers) and covered much of the present areas of Manitoba, North Dakota, and Minnesota. Between 1812 and 1816, Selkirk sent several parties of Scottish Highlanders and Irish to the Red River region around present-day Winnipeg. The immigrants founded the Red River Colony. See **Selkirk, Earl of**.

The early colonists suffered great hardships. Frosts, floods, and grasshoppers ruined many crops. At first, the settlers depended heavily on buffalo and other animals for meat. However, the colony lay in the heart of the North West Company's area of operations. As the colony expanded, there was much competition for food, especially buffalo meat. The North West Company became increasingly hostile. It turned local residents, including the *métis* (people of mixed white and Indian descent), against the colonists. The métis attacked the colony in 1815. In 1816, they killed Robert Semple, the colonial governor, and 20 others in the Battle of Seven Oaks. Peace came when the North West Company and the Hudson's Bay Company merged in 1821.

The Red River Rebellion. The Dominion of Canada, a union of four provinces, was created in 1867. In 1869, it arranged the transfer of almost all of Rupert's Land from the Hudson's Bay Company to itself in return for $1\frac{1}{2}$ million and land concessions. This area included the Manitoba region and the Red River Colony. The métis feared they would lose their land to settlers who would rush in after the area became part of the Dominion of Canada. The métis and other local inhabitants opposed the transfer. Louis Riel, the leader of the métis, directed a rebellion in 1869. See **Red River Rebellion**.

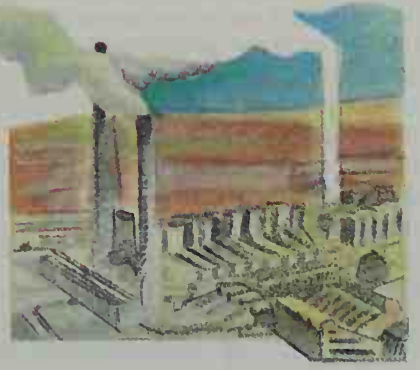
In 1870, the Canadian government granted the métis a bill of rights in the Manitoba Act. This act made Manitoba Canada's fifth province on July 15, 1870. The new province covered only the southeastern corner of present-day Manitoba, including the old Red River settlement. Winnipeg became the capital, and Alfred Boyd was the first premier.



Growth as a province. The expected rush of settlers into Manitoba began after 1870. Between 1871 and 1881, the population more than doubled, rising from 25,228 to 62,260. Most of the new arrivals came from Ontario.

In 1876, Manitoba began to export wheat. Farmers in the Red River Valley shipped wheat south along the Red River to Minnesota and to Toronto, Ontario. Wheat soon replaced fur as Manitoba's most valuable product. In 1878, the first railroad in the province connected Winnipeg and St. Paul, Minnesota. In 1881, other lines linked Winnipeg with cities in eastern Canada and the wheat-

Historic Manitoba



Sir Thomas Button and his crew reached the west coast of Hudson Bay in 1612. They were the first white people in the Manitoba region.

The first permanent settlement in Manitoba, the Red River Colony, was established in 1812 by Scottish and Irish settlers.

Flin Flon became a mining center in 1930 with the start of operations there by the Hudson Bay Mining and Smelting Company. Flin Flon has deposits of copper and zinc.

Louis Riel led people of mixed white and Indian descent called *métis* in the Red River Rebellion in 1869.

Canada's first transcontinental train arrived in Winnipeg in 1886.

WORLD BOOK illustrations by Kevin Chadwick

Important dates in Manitoba

1612 Sir Thomas Button, leader of the first white people in Manitoba, explored the west coast of Hudson Bay.

1690-1692 Henry Kelsey of the Hudson's Bay Company explored inland from Hudson Bay to what is now southern Manitoba.

1738 Pierre Gaultier de Varennes, Sieur de La Vérendrye, a French-Canadian fur trader, arrived at the site of present-day Winnipeg.

1812 Settlers sent by the Earl of Selkirk established the Red River Colony.

1869-1870 The métis revolted against the Canadian government in the Red River Rebellion.

1870 Manitoba became Canada's fifth province.

1876 Manitoba farmers began exporting wheat.

1878 The first railroad in Manitoba connected Winnipeg and St. Paul, Minnesota.

1912 The Canadian government extended Manitoba's northern boundary to Hudson Bay.

1960 Nickel mining operations began in Thompson.

1969 The voters of Manitoba elected the first Socialist government in Canada outside Saskatchewan.

1972 Winnipeg and its suburbs merged into one city, making Winnipeg one of Canada's largest cities.

1985 The Supreme Court of Canada ruled that all of Manitoba's laws, written only in English, must be translated to French.

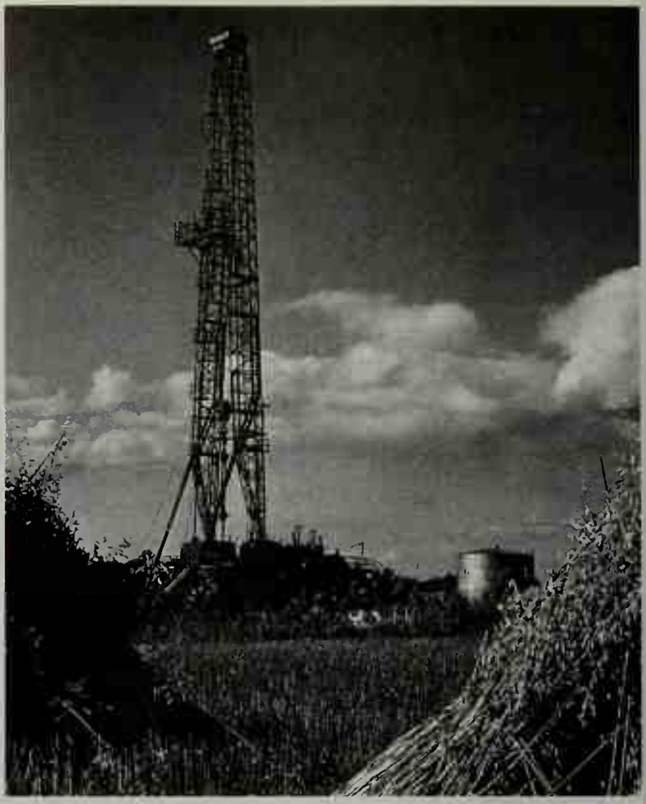
producing regions with Lake Superior. Manitoba grain could then be shipped to Canadian and European markets through ports on the Great Lakes.

Beginning in the 1890's, Manitoba experienced a major wave of new settlers. Many settlers came from eastern Canada and many others from the United Kingdom and other areas of Europe. The production of grain expanded rapidly, especially from 1900 to 1913. During these prosperous years, Winnipeg became the rail center for the entire prairie region of Canada.

By 1901, Manitoba's population had increased to more than 10 times that of 1871. The Canadian government extended the provincial boundary west to what is now Saskatchewan in 1881, and east to Ontario in 1884. In 1912, the northern boundary was extended to Hudson Bay, giving Manitoba its present size and shape.

Economic developments. Manitoba's boundary extension to Hudson Bay opened up lands for mineral development, and military needs of World War I encouraged exploration. In 1915, prospectors discovered huge deposits of copper and zinc on the site of Flin Flon. Mining operations became fully developed in 1930, and the town soon began to develop rapidly.

Cheap power, plentiful water, and availability of labor encouraged the growth of many industries during the 1920's and 1930's. A pulp and paper plant opened in Pine Falls in 1927. Fur processing and clothing trades developed rapidly in Winnipeg during the 1930's.



Political developments. Between 1878 and 1922, Manitoba was governed alternately by the Conservative and Liberal parties. The Liberal administration of Thomas Greenway (1888-1900) presided over the expansion of railroads and settlement.

The Conservative Party, led by Sir Rodmond P. Roblin, a Winnipeg grain dealer, controlled the government from 1900 to 1915. It concentrated on economic development and boundary expansion. The Liberal government of Tobias C. Norris ran the province from 1915 to 1922 and passed much reform legislation. Some of these reforms provided for female suffrage, workers' compensation, compulsory education to age 14, and rural farm credit. In spite of the reforms, however, Winnipeg remained a hotbed of labor unrest during World War I (1914-1918). The city's labor problems erupted into the Winnipeg General Strike of 1919, in which 52 unions struck at once. The federal government and citizens groups worked to keep the province's services running, and the strike failed.

In 1922, a group of organized farmers defeated the Liberal government. They formed a new progressive government under John Bracken, the principal of the Manitoba Agricultural College. Bracken urged a union of parties. This union occurred in 1932, when the Liberal and Progressive parties merged to form the Liberal Progressive Party.

The Great Depression of the 1930's created much hardship in Manitoba. Farm prices, especially for grain, were extremely low. The province, still dependent on agriculture, suffered widespread unemployment.

During the 1930's, two new political parties appeared in Manitoba. The Co-operative Commonwealth Federation, later called the New Democratic Party, was made up of farmers and factory workers. The other was the Social Credit Party. Its members believed that governments should pay all citizens a dividend based on economic production.

Provincial Archives of Manitoba

Large oil fields near Virden were developed during the early 1950's. Geologists also discovered important deposits of copper, nickel, and zinc in Manitoba during the 1940's and 1950's.

The mid-1900's. World War II (1939-1945) created a great demand for Manitoba cattle, metals, wheat, and wood. Many industries built new plants in the province during the war, and manufacturing continued to grow rapidly in the late 1940's. By 1950, for the first time in Manitoba's history, manufacturing outranked agriculture as the province's main source of income.

After World War II, Manitoba began to need fewer farmworkers because of the increased use of machines and new farming methods. Thousands moved from rural areas to cities and found jobs in factories and service industries.

Geologists discovered important mineral deposits in Manitoba during the 1940's and 1950's. Copper, nickel, and zinc ores were found in a northwestern area in 1945. Oil companies developed rich oil fields near Virden in the early 1950's. In 1956, prospectors found huge nickel deposits in the Moak Lake-Mystery Lake area. The International Nickel Company of Canada, Limited (now Inco Limited), built a complex at Thompson, and nickel mining began there in 1960. Thompson became one of the world's largest nickel-producing centers.

The province continued to develop its rich sources of electric power in the 1950's and 1960's. By 1954, all rural areas had electric service. In 1963, the first laboratories began operating at the Whiteshell Nuclear Research Establishment at Pinawa, near Winnipeg. A nuclear reactor went into operation there in 1965.

The biggest growth, however, was in the service and public sectors. By 1970, the federal, provincial, and local

governments were the largest employers in Manitoba.

The Liberal Progressive Party governed Manitoba during the 1940's and most of the 1950's. The Progressive Conservative Party won power in 1958 and held it until 1969. That year, voters elected the first socialist government ever to hold office in Canada outside Saskatchewan. The government was headed by Edward R. Schreyer of the New Democratic Party. The Progressive Conservatives regained control of the government in 1977. Sterling R. Lyon became premier.

Recent developments. In the late 1970's and early 1980's, problems arose concerning French language rights. French had been removed as an official language of Manitoba in 1890. In 1979, however, this removal was ruled unconstitutional by the Supreme Court of Canada. In 1980, the constitutionality of speeding tickets issued only in English was challenged in court.

The New Democratic Party returned to power in 1981, with Howard R. Pawley as premier. The government offered the French-speaking community translation of key legislation and extension of some French-language services throughout the province in return for an end to constitutional challenges. But it was unable to enact the compromise package. In 1985, the Supreme Court of Canada ruled that all of Manitoba's 4,500 laws, which were enacted in English only, must be translated into French. In 1988, the Progressive Conservatives returned to power, with Gary Filmon as premier. In 1999, the New Democratic Party regained control, and Gary Doer became premier.

The debate over providing widespread services in French continues. The province faces other major issues as well. Much of central Winnipeg has become rundown. In addition, the provincial debt has risen rapidly as the government has increased public services without a major raise in taxes. Still, because the province's economy is based on a variety of goods and services, Manitoba has remained relatively stable. The cost of living, especially in Winnipeg, is among the lowest in Canada. Provincial unemployment has remained at well under 10 percent of the labor force. Furthermore, the province's population has grown steadily since the early 1980's. John S. Brierley and J. M. Bumsted

Manitoba, University of, is western Canada's oldest university and the largest school in Manitoba. It is a coeducational, government-supported school and has its main campus in Fort Garry, a suburb of Winnipeg. The university was founded in Winnipeg in 1877. The university offers undergraduate degrees in agriculture, architecture, arts, dentistry, education, engineering, fine arts, human ecology, law, management, medicine, medical rehabilitation, music, nursing, pharmacy, physical education and recreation studies, science, and social work. The Faculty of Graduate Studies offers graduate degrees

in most of these areas. Four colleges are affiliated with the university. They are St. John's, St. Paul's, St. Andrew's, and St. Boniface colleges. St. Boniface College offers its classes in French. The University of Manitoba also has a smaller campus in Winnipeg with a focus on the health sciences. Critically reviewed by the University of Manitoba

Manitoulin Island, *MAN ih TOO lihn,* in Lake Huron, is famed for its resorts. The island is part of Ontario. It lies northwest of Georgian Bay and is separated from the north shore of Lake Huron by the North Channel. Manitoulin is formed by the northern section of the Niagara Escarpment. It is the world's largest inland island, covering an area of 1,067 square miles (2,764 square kilometers).

Chippewa Indians named the island for their great god Manitou, whose home they believed it to be. Many Indians live on Manitoulin. The island has several Indian reservations.

A *causeway* (raised road) from Little Current in the northeastern part of the island connects Manitoulin to mainland Ontario. Ferry service is provided between the island and the mainland. George B. Priddle

Mann, Horace (1796-1859), played a leading role in establishing state-supervised, state-funded, mandatory-attendance school systems in the United States. He worked to reduce the number of schools that were funded and controlled by local communities. Mann believed that, especially in rural areas and in the South and West, too much local control would result in some children receiving too little or improper schooling.

Mann gave up a law practice and a seat in the Massachusetts legislature in 1837 to become secretary of the newly established Massachusetts State Board of Education. As secretary, his speeches and 12 annual reports on education were influential in changing the definition of *common school.* The term had long applied to one-room, community-based schools. After Mann's work, only tax-supported schools graded by age and organized within township units were called common or *public* schools. In 1839, Mann helped found the country's first state-supported *normal school* (teacher-training school), in Lexington, Massachusetts.

Mann resigned from the State Board of Education in 1848 to take a seat in the United States House of Representatives as an antislavery Whig. Mann was defeated as a Free Soil Party candidate for governor of Massachusetts. He was president of Antioch College (now Antioch University) in Yellow Springs, Ohio, from 1853 until his death.

Mann was born on May 4, 1796, in Franklin, Massachusetts, and graduated from Brown University. He began his public career as a member of the Massachusetts state legislature in 1827. He was elected to New York University's Hall of Fame when it was established in 1900 to honor prominent Americans. Glenn Smith

Mann, *mahn,* **Thomas** (1875-1955), a German novelist, won the 1929 Nobel Prize in literature. His writings combine wisdom, humor, and philosophical thought. His intellectual scope, keen psychological insight, and critical awareness of cultural and political conditions made him one of the foremost humanistic writers of his time. Mann's writing has a tone of gentle irony, which creates an atmosphere of artistic detachment and tolerance. He often wrote in a highly stylized, stilted manner as a parody of earlier writers, especially Johann Wolfgang von Goethe.

A superb literary craftsman, Mann maintained a balance in his writings between the traditional realism of the 1800's and experimentation with style and structure. He was a critical, yet sympathetic, analyst of European middle-class values and attitudes. The central theme in his writings is a dualism between spirit and life. Mann expressed *spirit* as intellectual refinement and creativity, and *life* as naive and unquestioning vitality. He often presented this dualism through the conflict between the attitudes of the artist and the middle class.

Mann's first novel, *Buddenbrooks* (1901), made him famous. It describes the physical decline and accompanying intellectual refinement of a merchant family similar to Mann's. Variations on this theme appear in two shorter works, *Tristan* (1903) and *Tonio Kröger* (1903). The short novel *Death in Venice* (1912) portrays a writer's moral collapse through an uncontrollable and humiliating passion for a young boy.

Mann completed the novel *The Magic Mountain* in 1924, after working on it for 12 years. In the book, patients of a tuberculosis sanitarium represent the conflicting attitudes and political beliefs of European society before World War I. Mann's longest work is *Joseph and His Brothers* (1933-1943), a series of four novels. In this series, Mann expands on the Biblical story of Joseph by analyzing it from the standpoint of psychology and mythology.

Doctor Faustus (1947) is Mann's most despairing novel. In it, a German composer rejects love and moral responsibility in favor of artistic creativity. His story symbolically parallels the rise of Nazism. *Confessions of Felix Krull, Confidence Man* (1954) is a delightful novel about a rogue's adventures in middle-class society.

Mann's essays deal with politics, literature, music, and philosophy. Collections include *Order of the Day* (1942) and *Essays of Three Decades* (1947). *Last Essays* was published in 1959, after his death. Many volumes of his letters and diaries have also been published.

Mann was born into a wealthy merchant family in Lübeck, on June 6, 1875. He left Germany when the Nazis took power and lived in Switzerland from 1933 to 1938, when he moved to the United States. He became a U.S. citizen in 1944. He returned to Switzerland in 1952 and died there. His brother, Heinrich Mann, and his son, Klaus Mann, were also writers. Werner Hoffmeister

Manna, *MAN uh,* in the Old Testament, was the food given by God to the Israelites during their 40 years of wandering in the wilderness (Exodus 16 and Numbers 11). It consisted of round, yellowish-white flakes and tasted like wafers made with honey. Manna appeared with the dew each morning. It was gathered early be-

cause it melted in the sun. The daily portion of each person was an *omer.* Estimates of the size of an omer range from about 2 quarts (1.9 liters) to about 4 quarts (3.8 liters). The people gathered up just enough food for each day. The manna spoiled and was unfit to eat if more was gathered. But twice the usual amount was said to fall on the sixth day. Each person then took two omers, because the Sabbath was a day of worship and rest. This manna stayed fresh two days. The fall stopped when the Israelites crossed into Canaan, the Promised Land. Some historians say manna was a gluey sugar from the tamarisk shrub. H. Darrell Lance

Mannerism was a style of European art that flourished from about 1520 to 1600. The style appears most fully and typically in central Italian art. However, some mannerist traits can be found in all European art of the time, including architecture and the late works of the great Renaissance artists Raphael and Michelangelo.

Mannerist artists tended to value artistic invention and imagination more than faithful reproduction of nature. Space in many mannerist paintings appears illogical or unmeasurable, with abrupt and disturbing contrasts between figures close to the viewer and those far away. Most of the paintings stress surface patterns. Strongly three-dimensional forms compressed within these patterns create an effect of confinement or of a struggle between a figure and its setting. Many figures in mannerist paintings are distorted in proportion and have contorted poses.

Mannerism was an elegant, courtly style. It flourished in Florence, Italy, where its leading representatives were Giorgio Vasari and Bronzino. The style was introduced to the French court by Rosso Fiorentino and by Francesco Primaticcio. The Venetian painter Tintoretto was influenced by the style. El Greco brought mannerism from Venice to Spain, where he developed it in his own distinctive way.

The mannerist approach to painting also influenced other arts. In architecture, the work of Italian architect Giulio Romano is a notable example. The Italians Benvenuto Cellini and Giovanni Bologna were the style's chief representatives in sculpture. Eric M. Zafran

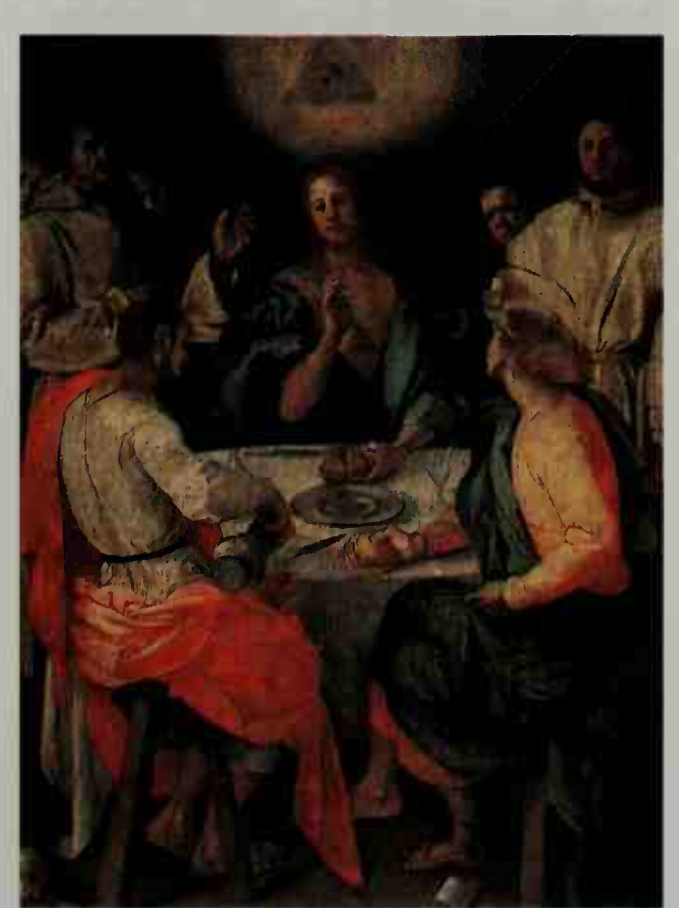
Manners and customs. See **Custom; Etiquette.**

Mannheim, *MAN hym* (pop. 294,984), is a city in southern Germany. It lies near the point where the Neckar and Rhine rivers meet (see **Germany** [political map]). Mannheim is the center of a major industrial area. Its chief products include chemicals, machinery, and precision instruments. Together with the nearby city of Ludwigshafen, it forms an important river port.



A fishing village existed on the site of Mannheim as early as the 700's. German officials began building the city there in the 1600's. They laid out the city in an orderly pattern of rectangular city blocks and constructed many buildings in the baroque style. Mannheim's chief baroque building is the Residence of the Elector. Built as a palace in the early 1700's, it now houses Mannheim University and many art treasures. Much of Mannheim was damaged in World War II (1939-1945). The damaged areas were rebuilt, giving much of Mannheim a modern appearance. Peter H. Merkl

Manning, Preston (1942-), was leader of Canada's Reform Party from 1987 to 2000. He helped found the party in 1987 to push for political reforms and reducing the national debt. Under Manning's leadership, the Reform Party won prominence during the 1990's. In the general election held in 1997, the party won more seats in the Canadian House of Commons than any other party except the Liberal Party. As a result, the Reform Party became Canada's official opposition party. In 2000, members of the Reform Party voted to join the newly created Canadian Alliance. The new party, officially called the Canadian Reform Conservative Alliance, then became the official opposition in the House of Commons.

Ernest Preston Manning was born in Edmonton, Alberta. His father, Ernest Charles Manning, was premier of Alberta from 1943 to 1968. The younger Manning graduated from the University of Alberta in 1964. He and his father coauthored the book *Political Realignment* (1967), which called for an end to Canada's traditional two-party system. In *The New Canada* (1992), Preston explained the Reform Party's goals. Before Manning became leader of the Reform Party, he worked as a management consultant for oil and utility companies and government agencies. Graham Fraser

Manometer, *muh NAHM uh tuhr,* is an instrument used to measure the pressure of a gas or vapor. There are several types of manometers. The simplest kind consists of a U-shaped tube with both ends open. The tube contains a liquid, often mercury, which fills the bot-

Supper at Emmaus (1525), an oil painting on canvas by Jacopo Pontormo; Uffizi Gallery, Florence (SCALA/Art Resource)

A mannerist painting shows the exaggeration, distorted space, and elongated figures that give the style its strong dramatic quality. Mannerism flourished in Italy in the 1500's.

tom of the U and rises in each of the arms. The person using this type connects one of the arms to the gas whose pressure is to be measured. The other arm remains open to the atmosphere. In this way, the liquid is exposed to the pressure of the gas in one arm and atmospheric pressure in the other.

If the pressure of the gas is greater than that of the atmosphere, the liquid rises in the arm of the tube exposed to the air. The user measures the difference between the heights of the liquid in the two arms to determine the pressure of the liquid. The liquid pressure is equal to the product of the measured height difference and the *specific weight* (weight per unit volume) of the liquid. The sum of the liquid pressure and the atmospheric pressure is the gas pressure.

In some manometers, the air is removed from one arm of the tube and that end is sealed. This eliminates the need for corrections due to changes in atmospheric pressure. The difference between the levels of the liquid in the arms shows the pressure of the gas. Gas pressure is often measured in units of the height of the liquid. For example, manometers called *barometers* may measure atmospheric pressure in centimeters of mercury (see **Barometer**). Some manometers work on the principle of a spring attached to an indicator. The indicator moves in front of a graduated scale that gives pressure readings. Physicians measure blood pressure with a manometer called a *sphygmomanometer.* Richard A. Martin

Manor. See Manorialism.

Manorialism was an economic system that spread through Europe after the Roman Empire ended in the late A.D. 400's. The name comes from a Latin word for *manor,* a large estate controlled by a lord and worked by peasants. Manors covered most of Europe. They supplied food, clothing, shelter, and nearly everything else needed by the lords and peasants.

Most manors were made up of the lord's land and small plots of land held by the peasants. The lord lived in a manor house, which was usually surrounded by a garden, an orchard, and farm buildings. The peasants' huts were clustered nearby. Most manors also included a church, a mill for grinding grain into flour, and a press for making wine.

The peasants depended on the lord for protection from enemies, for justice, and for what little government there was. The peasants farmed both the lord's land and their own. Many peasants were *serfs* and, as such, were *bound to the soil.* This means that they were part of the property, and they remained on the land if a new lord acquired it. Peasants rarely traveled far from the manor.

Manorialism began to decline when trade and industry revived. This revival brought back an economic system based on payment with money for goods and services. Manorialism ended in some parts of western Europe as early as the 1000's. It remained as late as the 1800's in parts of central and eastern Europe. Large family estates in the United Kingdom and other parts of Europe still exist as reminders of manorialism. Bryce Lyon

Manpower. See **Labor force.**

Mansa Musa, *MAHN sah MOO sah* (? -1337?), also known as Kankan Mousa, was the ruler of the Mali Empire in Africa from 1312 to about 1337. He was a great-nephew of Sundiata Keita, the empire's founder. Mansa Musa greatly expanded Mali and made it West Africa's political and cultural power. He brought the trading cities of Gao, Walata, and Timbuktu under his rule and made Timbuktu a center of learning.

Mansa Musa spread Islam, the Muslim religion, throughout the empire. In 1324, he traveled to Mecca, the holy city of the Muslims. Mansa Musa's party supposedly included thousands of his people and hundreds of camels bearing gold and gifts. He brought back many learned people, including an architect who designed *mosques* (Muslim houses of worship) for Gao and Timbuktu. After Mansa Musa died, his son Mansa Magha I became ruler of the empire. Kevin C. MacDonald

Mansfield, Arabella Babb (1846-1911), was the first woman admitted to the practice of law in the United States. She did not work as a lawyer but instead pursued a college teaching career.

Mansfield was born on May 23, 1846, on a farm near Burlington, Iowa. She graduated from Iowa Wesleyan College. Her original name was Belle Aurelia Babb, but she came to be called Arabella. In 1868, she married John Melvin Mansfield, a professor of natural history. The couple joined the faculty of Iowa Wesleyan, where Arabella taught English and history. She studied law and was admitted to the legal profession in 1869. In 1870, she helped found the Iowa Woman Suffrage Association, which worked to gain voting rights for women.

In 1879, the Mansfields moved to Indiana Asbury University, now DePauw University. There, Arabella became dean of the school of art in 1893 and dean of the school of music in 1894. She held both positions until her death on Aug. 1, 1911. June Sochen

Mansfield, Katherine (1888-1923), a British author, wrote symbolic short stories about everyday human experiences and inner feelings. She has often been compared to the Russian author Anton Chekhov in her mastery of the forms of short fiction. Many of her stories are studies of childhood, based on her early years in Wellington, New Zealand. Mansfield often used herself and her brother as models for the main characters. Her stories were published in *In a German Pension* (1911), *Prelude* (1918), *Bliss* (1920), and *The Garden Party* (1927). Her *Journal* (1927) gives a fascinating picture of her mind and the development of her writing.

Bettmann Archive
Katherine Mansfield

Katherine Mansfield was born Kathleen Mansfield Beauchamp on Oct. 14, 1888, in Wellington. She began her literary career after moving to England in 1908. She suffered from tuberculosis, and spent much of her life in hospitals and sanitariums. She died on Jan. 9, 1923. Jane Marcus

Mansfield, Mike (1903-2001), a Montana Democrat, served as majority leader of the United States Senate from 1961 to 1977, longer than any other person. He served as a member of the U.S. House of Representatives for 10 years before he was elected to the Senate in 1952. From 1977 to 1988, he was U.S. ambassador to

Japan under Presidents Jimmy Carter and Ronald Reagan. Mansfield also carried out foreign assignments for Presidents Dwight D. Eisenhower, John F. Kennedy, and Lyndon B. Johnson.

Michael Joseph Mansfield was born in New York City and was raised in Montana. At the age of 14, he dropped out of eighth grade and joined the U.S. Navy. He served as a seaman during World War I, spent the next year as a private in the U.S. Army, and was in the U.S. Marine Corps from 1920 to 1922. Mansfield worked as a miner and mining engineer from 1922 to 1930. Although he never went to high school, he graduated from Montana State University in 1933 and earned a master's degree there in 1934. Mansfield taught Latin-American and Far Eastern history at Montana State until he entered Congress in 1943. Mansfield served in the U.S. Senate from 1953 to 1977. William J. Eaton

Mansfield, Richard (1854-1907), was the leading actor in the American theater from the 1880's to the early 1900's. Mansfield won acclaim for his performances in such classics as *Richard III* and *Henry V* by William Shakespeare. He also starred in works by modern playwrights, notably George Bernard Shaw and Henrik Ibsen. Mansfield became especially popular for his skillful physical impersonation of characters. His most famous performance was in the dual role of Dr. Jekyll and Mr. Hyde, in a dramatic adaptation of a famous horror story by Robert Louis Stevenson.

Mansfield was born in Berlin, Germany, to an English father and a Dutch mother. He lived in England and elsewhere in Europe before coming to the United States at the age of 18. Mansfield moved back to England in 1877. He made his American professional acting debut in 1882. Stanley L. Glenn

Manslaughter is the legal term for the wrongful unplanned killing of another person. It is different from *murder* in that it is not done with malice.

The law recognizes two kinds of manslaughter, *voluntary* and *involuntary.* Voluntary manslaughter, also called *nonnegligent manslaughter,* is a killing done in a heated moment, without previous plan, and in reaction to provocation by the victim. This provocation is such that it would enrage a person for a period in which an ordinary person would not have calmed down. A person who kills someone in a violent quarrel without first planning to do so is guilty of voluntary manslaughter. Involuntary manslaughter, also called *manslaughter by negligence,* is done while the offender is engaged in some wrongful act. If a reckless driver kills someone, the driver is guilty of involuntary manslaughter.

Punishment for manslaughter varies by state and country. The usual penalty in the United States is imprisonment for 1 to 14 years. Charles F. Wellford

See also **Homicide; Murder**.

Manson, Sir Patrick (1844-1922), a Scottish physician, was called the *father of tropical medicine.* He demonstrated in 1877 that the parasite *Filaria* caused the disease elephantiasis. He later showed that mosquitoes carried the parasite (see **Filaria**). In 1894, Manson suggested that mosquitoes also transmitted malaria to human beings, a theory later proven by the British physician Sir Ronald Ross. In 1900, Manson confirmed Ross's findings.

Manson was born in Aberdeenshire (now Grampian Region), Scotland. Soon after graduating from the Aberdeen Medical School in 1866, he traveled to China, where he worked for 24 years. He helped establish the London School of Tropical Medicine in 1899.

Kenneth R. Manning

Manta ray. See Ray; Fish (picture: Fish of coastal waters and the open ocean).

Mantegna, *mahn TEH nyah,* **Andrea,** *ahn DREH ah* (1431-1506), was a leading painter of the Italian Renaissance. He painted sculpturelike figures that are sharply outlined and precisely detailed. The surfaces of his figures seem like marble. Mantegna used perspective for dramatic effects, with many figures appearing as if seen from below. He was also a famous engraver. Mantegna's engravings influenced many other painters, including the famous German artist Albrecht Dürer.

Mantegna was born in Isola di Carturo, Italy, near Padua. He received his early art training in Padua and soon earned a reputation as a painter. In 1459 or 1460,

The Risen Christ Between Saint Andrew and Saint Longinus (about 1500); Rijksprentenkabinet, Rijksmuseum, Amsterdam, the Netherlands

An engraving by Mantegna shows the sculpturelike figures and precise details that are typical of the artist's style.

he entered the service of the ruling Gonzaga family in Mantua. Mantegna spent the rest of his life there and painted the Gonzagas in superb frescoes. Mantegna also painted several portraits and altarpieces.

David Summers

Mantid is an insect that is sometimes called *praying mantis* because it usually holds its front legs as if it were praying. Most mantids live in tropical or warm climates. But the *European mantid* is native to cool parts of Europe. It was introduced to the Rochester, New York, area about 1899 and has since spread through the Eastern United States.

Mantids prey on other insects, including other man-

tids. They even seize and eat small tree frogs. A female mantid will sometimes devour her own mate, but the male is able to continue mating with the female even after his head and brain have been eaten.

A full-grown mantid measures from 2 to 5 inches (5 to 13 centimeters) in length, depending on the species. Mantids resemble the color, and sometimes the form, of the plants on which they stay. As a result, predators often fail to see them. A mantid uses its armlike forelegs to grasp and capture its prey. The forelegs have sharp spines and hooks that hold captives.

Female mantids lay their eggs in masses. The eggs can be found attached to trees and shrubs during the winter when leaves no longer hide them. The eggs are light brown and ribbed. James E. Lloyd

Scientific classification. Mantids are usually classified in the order Mantodea. They make up the mantid family, Mantidae.

Mantissa. See **Logarithms** (Common logarithms).

Mantle is a membrane or a tissue. See **Oyster** (Shell; diagram); **Shell** (How shells are formed).

Mantle is the layer of rock between Earth's crust and core. The mantle makes up approximately 83 percent of Earth's volume and about 67 percent of its *mass* (amount of matter). Movements within the mantle cause volcanic eruptions, most earthquakes, and *continental drift* (the slow movement of land masses). Mercury, Venus, and Mars also have mantles.

Most of Earth's mantle rock is peridotite (pronounced *PEHR uh DOH tyt*), which is composed mostly of silicon, oxygen, iron, and magnesium. The most abundant mineral in peridotite is olivine *(AHL uh veen)*.

The mantle is about 1,800 miles (2,900 kilometers) thick. The top of the mantle lies about 4 $\frac{1}{2}$ miles (7 kilometers) beneath the ocean floor. Under the continents, the average depth of the top of the mantle is about 20 miles (32 kilometers).

The temperature at the top of the mantle is less than about 1300 °F (700 °C) under continental crust. At the bottom, where the mantle comes in contact with Earth's outer core, the temperature is approximately 7000 °F (4000 °C).

Mantle rock that is hotter than about 2400 °F (1300 °C) can flow much as a glacier creeps down a mountain valley. Over much of Earth, from depths of about 60 to 150 miles (100 to 240 kilometers), the mantle is partly *molten* (melted). This part of the mantle, known as the *asthenosphere (as THEHN uh SFIHR)*, is very weak.

The cooler overlying mantle and the crust make up huge *lithospheric plates* that move slowly on the asthenosphere. The continents are embedded in the tops of some plates, and so plate movement causes continental drift. Mark Cloos

See also **Earth** (table: Inside Earth); **Olivine; Plate tectonics; Rock** (Igneous rock).

Mantle, Mickey (1931-1995), ranks among the leading home run hitters in baseball history. Mantle hit 536 home runs in regular season play. He spent his entire major league career with the New York Yankees —from 1951 through 1968. He mainly played center field and was a switch hitter.

Mantle led the American League in home runs four times. He was named the most valuable player in the American League three times. Mantle hit 18 World Series home runs, a record. Unlike most sluggers, he had great speed. However, various leg injuries reduced Mantle's base running effectiveness during the 1960's.

Mickey Charles Mantle was born in Spavinaw, Oklahoma. He was elected to the National Baseball Hall of Fame in 1974. Mantle's autobiography, *The Mick*, was published in 1985. Dave Nightingale

Mantra. See **Buddhism** (The Mantrayana); **Transcendental meditation.**

Manu, *MAN oo*, in Hindu mythology, was the man who systematized the religious and social laws of Hinduism. These ancient laws are called the *Manu Smriti (Code of Manu)*. They still influence the religious and social life of India, where Hinduism is the chief religion. The *Manu Smriti* has three main parts: (1) *varna*, (2) *ashrama*, and (3) *dharma*.

Varna sets forth the basis of *caste*, the strict Hindu class system. Hinduism has four major *varnas* (groups of castes). See **Hinduism** (Caste).

Ashrama describes the four ideal stages of a Hindu man's life. First, he studies Hindu scriptures called the *Vedas*, and the duties of his caste. Second, he marries. Third, after he fulfills his family obligations, he retires with his wife to a forest to meditate. Finally, in old age, the husband and wife separate and wander as beggars called *sannyasis*, preparing for death.

Dharma describes the four goals of life. They are (1) *dharma*—fulfilling one's religious obligation in society, (2) *kama*—enjoying sex and other physical pleasures, (3) *artha*—achieving worldly success through one's occupation, and (4) *moksha*—gaining spiritual release from worldly existence. Charles S. J. White

Manual training. See **Industrial arts.**

Manuelito, *mahn yoo ayl EE toh* (1818?-1893), was a leader of the Navajo Indians. He played an important part in the Navajo fight to prevent white settlers from taking over their land.

In 1860, following conflicts between the Navajo and the settlers, Manuelito helped lead an attack on Fort Defiance in what is now Arizona. The next year, he and other Navajo leaders signed a peace treaty with the United States. But fighting soon broke out again. In 1863 and 1864, U.S. Army troops led by the frontiersman Kit Carson forced thousands of Navajo to surrender. The Army did not capture Manuelito, but he surrendered in 1866.

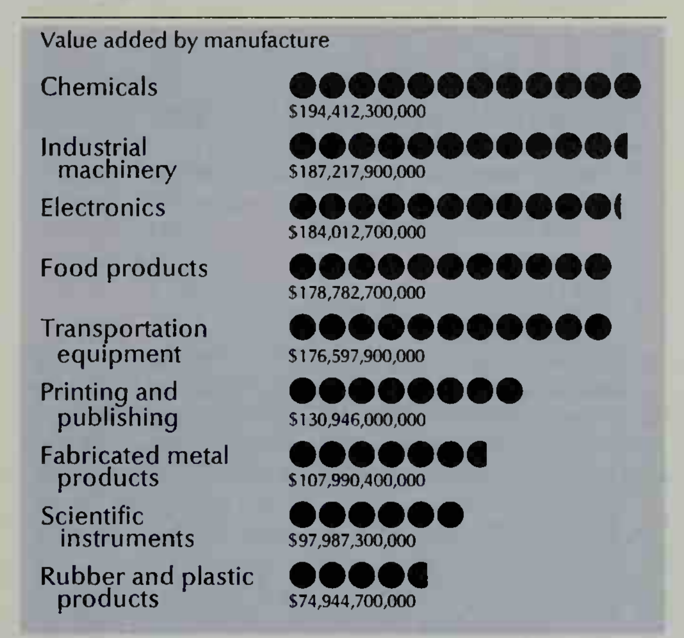
Smithsonian Institution, National Anthropological Archives, Washington, D.C.

Manuelito

In 1868, the United States government established a reservation for the Navajo in what became parts of Arizona, New Mexico, and Utah. Manuelito headed the first Navajo police force, which was founded in 1872 to protect the reservation. He was probably born in Bear's Ears, near what is now Moab, Utah. Ruth W. Roessel

Manufactured home. See Mobile home.

Manufacturers, National Association of. See National Association of Manufacturers.



Manufacturing is the industry that makes automobiles, books, clothing, furniture, paper, pencils, and thousands of other products. The word *manufacture* comes from the Latin words *manus* (hand) and *facere* (to make). Today, manufacturing means the making of articles by machinery as well as by hand.

Manufacturing plants have great importance to the welfare of their communities. When a factory hires 100 workers, for example, it also creates about 175 jobs outside the factory. These include jobs for people in restaurants, stores, and other businesses that provide the factory employees with goods and services.

Until the early 1900's, the greatest manufacturing centers were in western Europe. The United States became the leading manufacturing nation during World War I (1914-1918). Since then, the United States has ranked as the greatest producer of manufactured goods.

Manufacturing is an important industry in the United States and Canada. It earns about one-fifth of the *gross domestic product* (GDP) of each nation. GDP is the value of all the goods and services produced in a country within a given period. Manufacturing employs about one-fifth of the two nations' workers.

Leading manufactured products in the United States

Figures are for 1996. Source: U.S. Department of Commerce.

Kinds of manufacturing

Manufactured items may be divided into heavy or light, and durable or nondurable goods. A *durable* product lasts for a long time. A *nondurable* product is used up quickly. A locomotive is a heavy durable product. A loaf of bread is a light nondurable item.

All manufactured products are either consumer goods or producer goods. Retail stores, such as groceries or drugstores, sell *consumer goods* to millions of buyers. These products include radios, rugs, food, and thousands of other items. *Producer goods* are products used to make other products. They include springs, bearings, printing presses, and many other items.

Manufacturing around the world

Manufacturing industries are usually located in regions that have abundant natural resources, good transportation, mild climates, and large populations. North America, Europe, and Asia rank as leaders in all these categories. Together they produce over 90 percent of the world's manufactured goods.

In the United States, manufacturing companies operate more than 360,000 factories. These companies include individually owned firms, partnerships, and corporations. Much of the money invested in manufacturing is for the plant and equipment. The rest is represented by the inventory of materials waiting to be worked on or sold. Manufacturing firms employ about 18 million people and account for about $19 of every $100 earned in the nation.

Most big U.S. manufacturers are near large cities. The 15 major manufacturing regions, in order of importance, are Los Angeles-Long Beach, Chicago, New York City, Philadelphia, Detroit, Houston, Dallas-Fort Worth, Boston, St. Louis, Rochester, Newark, San Francisco-Oakland, Cleveland, Milwaukee, and Baltimore. See United States (Manufacturing).

In Canada. Canada ranks among the leading manufacturing countries. Its major manufacturing industry produces transportation equipment. Other important industries make food products, paper products, chemicals, electrical machinery and equipment, and primary metals. Ontario produces about half of Canada's manufactured goods. Quebec produces about a fourth. Canada has about 34,500 factories that employ about 1 $\frac{3}{4}$ million people. They produce goods with a *value added by manufacture* of about $100 billion a year in United States dollars. This figure represents the value created in products by industries, not counting such costs as materials, supplies, and fuel. See **Canada** (Manufacturing).

In Europe. Europe ranks after the United States as the world's main manufacturing region. The major

Leading manufacturing states and provinces

*In millions of United States dollars. Figures may include income from nonmanufacturing activities.
Source: "The Global 500," *Fortune,* July 23, 2001.

manufacturing nations of Western Europe are France, Germany, Italy, the Netherlands, Spain, Sweden, and the United Kingdom. Major manufacturing nations of Eastern Europe include Poland, Russia, and Ukraine. See **Europe** (Manufacturing).

In Asia, large-scale manufacturing is mostly centered in China, India, Japan, Russia, South Korea, and Taiwan. Most other countries produce only a few goods that workers make by hand. Japan is a major manufacturer, and it makes more products than any Western European country. Asia leads the world in silk production. See **Asia** (Industry).

In Africa, manufacturing plays a small role in the economy, except in South Africa. Africa has poor transportation and includes vast areas with sparse populations. The continent has about a third of the world's potential water power. But most of the sites for power plants are in regions where it would be hard to develop industries. Less than 1 percent of Africa's available water power is used. See **Africa** (Manufacturing).

In Latin America, manufacturing has gradually increased in importance. The region's leading manufacturing countries include Brazil and Mexico, which make such products as automobiles, chemicals, and steel. Many nations produce cement, processed foods, and textiles. A number of countries, including Mexico and Venezuela, manufacture petroleum products.

The main steps in manufacturing

Design and engineering. Manufacturers must design products that will be easy and safe to use, without being too expensive to make and ship. Makers of consumer goods often change the styles of their products. The new designs attract the public's interest and frequently include improvements on the old styles.

After the basic product design has been determined, engineers with different skills work to develop a *process plan,* a set of instructions for making the product. They often build and test a *prototype* (sample of the product) before selling the item.

Purchasing. The raw materials and purchased parts used in making the finished product must be bought and delivered to the plant. Raw materials come from farms, forests, fisheries, mines, and quarries. Some manufacturers, such as those that make food products, buy most of their raw materials from nearby areas. Others may require raw materials that must be shipped from the other side of the world. For example, Ohio manufacturers make the most tires in the world. But the rubber comes from Asia. Some manufacturers purchase parts that are already made. For example, automobile manufacturers buy finished tires and use them to build their own finished product—automobiles.

Making products involves one or more of three processes. These processes are (1) synthetic, (2) analytic, and (3) conditioning.

Manufacturers who use the *synthetic* process mix ingredients or assemble ready-made parts. A paint manufacturer mixes chemicals to produce paint, and an automobile company assembles parts to make a car.

In the *analytic* process, the manufacturer breaks down a raw material. Oil refineries break crude oil down into

gasoline, oil, and other parts. An analytic process performed at a packing house converts a hog to ham, bacon, and other pork products.

The *conditioning* process changes the form of raw materials. Ore from mines becomes *ingots* (bricks) or sheets of metal, which then may be formed into usable parts. Rocks from quarries are made into gravel.

Besides making the product, a manufacturer must have a system of *quality control.* Specially trained workers check the raw materials and examine the finished products, making sure the products meet company standards. Careful *production control* is also essential. Experts make sure that the right materials in the right amounts go to the proper place at the proper time.

Distribution and sales account for a large part of the prices we pay for products. For example, 1 gallon (3.8 liters) of paint costs much more than the chemicals and labor needed to manufacture it. The final price of a product includes the costs of advertising, packaging, shipping, storage, commissions to salespeople, office work, and taxes. In addition to these costs, the price must give a fair profit to the manufacturer, the wholesalers, and the retailers.

How science helps manufacturing

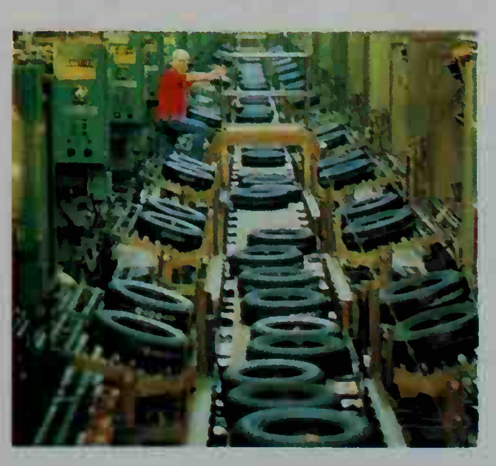
Engineers and scientists involved in industrial research continually work to develop new materials and processes that will benefit manufacturing. Such research often leads to lower manufacturing and product costs. Researchers also find new uses for old products and materials. Research begun in the early 1800's has yielded hundreds of kinds of plastics that manufacturers have used to replace less sturdy, less attractive, and more expensive materials (see **Plastics**). Until automobile companies developed the assembly-line method of manufacturing in the early 1900's, only the wealthiest families could afford automobiles (see **Assembly line**). Widespread industrial research began after World War I (1914-1918), when research became more and more important as a part of manufacturing.

Manufacturing often benefits from scientific advancements that are not the result of industrial research. For example, the Global Positioning System (GPS), a satellite network, enables manufacturers to track the movement of trucks carrying incoming and outgoing orders.

Computerization has improved efficiency in many aspects of manufacturing production and management. Most manufacturing plants maintain inventories of thousands of types of parts. Computers handle the large quantities of data required to keep accurate inventory records. Manufacturers also use computers to solve inventory problems, such as determining the quantity of an item to order and when to place the order.

Computer-based automated data-collection devices enable a manager to monitor the status of products as they are being made. Many types of manufacturing equipment have on-board computers. Such computers control the heating cycles of the large furnaces used to process raw materials and direct arc-welding robots to make the proper straight or curved weld.

Steps in manufacturing



The steps in manufacturing are the same for nearly all types of products, including the automobile tires shown in these photographs. First, the manufacturer designs the product. For example, a designer may use a computer to create the pattern for tire treads. Next, the producer buys the raw materials, such as bales of rubber from Indonesia. Then, the manufacturer produces and inspects the product. Finally, the products are distributed to stores, where customers may examine and purchase them.

Designing the product

Obtaining the raw materials

Making the product

Goodyear Tire and Rubber Company

Selling the product

The Internet aids manufacturers in dealing with their suppliers, distributors, and customers. Parts manufacturers use the Internet to track their customers' production activities and so are able to supply parts on a *just-in-time* basis. Many manufacturers order products and make payments electronically over the Internet.

How governments help manufacturing

Thousands of government laws and regulations protect a manufacturer's property. The government also provides legal ways to buy and sell property and to establish companies. Government helps keep money stable so that its value does not change greatly from day to day and from one area to another. The government permits manufacturers to patent new products or methods that they have developed (see **Patent**).

Governments furnish businesses with statistics that help them plan sales and purchases. They give manufacturers loans at low rates of interest, and sometimes give them *subsidies,* or outright grants (see **Subsidy**). Governments protect home industries by levying tariffs on goods imported from other countries (see **Tariff**). Many nations encourage manufacturers to build factories by not levying taxes on their profits for a certain period. Some governments fund manufacturing-related research at colleges and universities. Manure is any substance produced by animals or plants that is used as fertilizer. Most manure consists of animal waste mixed with straw or hay from barnyards, though it may be pure animal waste. This waste is collected and spread onto fields. When it decays, it releases important nutrients that enrich the soil and aid plant growth. Manure also loosens the soil and improves its ability to absorb water. A special kind of manure called *green manure* is obtained from plants that are plowed into the soil and allowed to decay.

The content of animal manure varies widely, depending on the kind of manure and whether it is fresh, dried, or partly decayed. Most animal manure in the United States is from the wastes of cattle and chickens. Horses, hogs, and sheep also provide manure. Animal manure is an excellent source of *organic matter* (substances containing carbon) for the soil. But it is low in such important nutrients as nitrogen, phosphorus, and potassium. In general, it takes about 2,000 pounds (907 kilograms) of manure to supply as much of these three substances as 100 pounds (45 kilograms) of a commercial fertilizer.

The most common green manure plants are grasses and *legumes.* Legumes belong to the pea family. They include alfalfa, beans, clover, and peas. Grasses and legumes provide the soil with organic matter. Legumes provide large amounts of nitrogen. Taylor J. Johnston

Manuscript is a term for any document written by hand or by a machine such as a typewriter or a personal computer. The word is often used to distinguish an author's original version of a work from the printed copy. In addition, manuscript refers to any handwritten document from ancient times until the introduction of printing in the 1400's. This article discusses such historical manuscripts.

Most manuscripts can be identified with certain times or areas by the material on which they were written. In ancient times, for example, people living around the Mediterranean Sea wrote manuscripts on papyrus, leather, and wax tablets. During the Middle Ages, manuscripts were written on parchment and on a refined form of parchment called *vellum.* By the 1400's, paper was replacing parchment for manuscripts. Paper made practical the printed books that became the principal means of transmitting the written word.

Ancient and medieval manuscripts tell about the lives and activities of people who lived hundreds and even thousands of years ago. Scholars learn from manuscripts about business transactions, customs and laws, family affairs, literature, government, and religious beliefs. Many of these manuscripts are also considered works of art because they are beautifully decorated or painted.

Manuscripts of the ancient Near East

Papyrus manuscripts. Papyrus was the principal writing material of the ancient Egyptians, Greeks, and Romans who lived in the lands surrounding the Mediterranean Sea. Papyrus manuscripts appeared as early as 2700 B.C. and continued in use even after parchment books became common in the A.D. 300's.

Papyrus was made from a tall, reedlike plant that grew in the swamps of the Nile River in Egypt. Papyrus was manufactured from the stem of the plant by removing the hard rind and cutting the fibrous core into long strips that were pressed together into sheets. The sheets, in turn, were pasted together to form scrolls or rolls. The scrolls varied in size but they averaged about 1 foot (0.3 meter) wide and 20 feet (6 meters) long.

The papyrus scroll was the manuscript book of the ancient world, but it had drawbacks. First, papyrus was a vegetable substance that decayed rapidly in damp climates. While it was satisfactory in the dry climate of Egypt, it was not durable enough for the damper European weather. Second, the scroll was awkward to read and difficult to use if the reader only wanted to locate one portion of the manuscript. Finally, it was possible to write on only one side of the papyrus.

Wax tablets. People of the Greek and Roman worlds also wrote on wax tablets with a sharp, pointed instrument called a *stylus.* On the end opposite the point, the stylus had a flat or rounded surface, which was used to erase the writing by smoothing the wax. Sometimes, several wax tablets were laced together on one side to form a *codex,* which became the ancestor of the book.

Parchment manuscripts. Parchment was made from cleaned and scraped skins, chiefly sheep, goat, or calf skins. It was an improved version of the animal skins used for ancient Persian and Hebrew religious writings. Sheets of parchment were trimmed into rectangles. About four sheets were stacked together, folded, and

Trinity College, Dublin, Ireland, The Green Studio Ltd.

The Book of Kells is an illuminated manuscript of the Gospels created in Ireland between the mid-700's and early 800's.

sewed at the fold to form a gathering. The entire manuscript could be bound between boards into a codex.

The parchment codex was more durable than the older papyrus scroll that it largely replaced. It could be read more easily, and could be conveniently stored on a shelf. Papyrus scrolls were often kept in bins or boxes. Both sides of parchment could also be used for writing.

Other manuscripts. Other materials were used for ancient manuscripts. From about 3500 B.C., the peoples of Mesopotamia wrote on small clay tablets that were baked like bricks to preserve them. Some manuscripts were written on the bark of various trees, on wood, or on thin sheets of copper that were rolled up.

Manuscripts of the ancient Far East

Paper manuscripts. The Chinese had invented paper by A.D. 1. Their first books written on paper took the form of scrolls. Later, they made books by folding long strips of paper into accordionlike pleats.

Before the Chinese invented paper, they wrote on bones and silk. They also wrote on bamboo strips that measured about $\frac{1}{4}$ inch (0.6 centimeter) wide and 6 to 9 inches (15 to 23 centimeters) long. They wrote on the strips in column form from top to bottom. Then they tied the strips together with string.

Palm leaf manuscripts. In ancient India and some surrounding lands, the people also made books of strips, only cut from palm leaves. They used strips about $1\frac{1}{2}$ to 3 inches (4 to 8 centimeters) wide and 24 inches (61 centimeters) or more long. They made holes in the strips and then strung them together, forming the books.

European manuscripts of the Middle Ages

Parchment and vellum were the chief writing materials in Europe during the Middle Ages. They were generally replaced by the 1400's by the adoption of paper and the invention of printing.

Until the 1200's, monks produced most medieval manuscripts in monastery workshops called *scriptoriums.* They were helped by outside craftworkers. Monasteries traded manuscripts for books made in other monasteries, and some were sold. In the 1200's, most book production shifted to lay craftworkers in cities.

Manuscript writers were called *scribes.* Their work was highly specialized. One group produced the parchment and another did the writing. A third decorated the manuscripts with designs or paintings, and a fourth group bound the finished pages into books.

Medieval scribes made important contributions to the development of modern books. For example, scribes separated words with spaces, while the Greeks and Romans had run words together without spacing. The scribes used capital and small letters and established a system of punctuation to make reading easier. Most of these developments occurred in the Carolingian period, during the late 700's and 800's in the scriptoriums of what are now France and western Germany.

Many manuscripts of the Middle Ages were beautifully decorated in various colors. Often, gold or silver leaf was used on the initial letters and the decoration. Such manuscripts were called *illuminated,* because they looked as if they had been lit from inside. Today, we use the term *illuminated* to refer to any decorated manuscript, whether or not it has gold or silver.

Distinctive styles of illumination developed in differ-

ent parts of Europe. There were, for example, Byzantine, English, French, Irish, and Italian styles of illumination. All these styles used six basic forms of decoration: (1) animals and human figures, (2) branches with leaves or berries, (3) geometric designs, (4) ornamental letters,(5) *plaits* (braids), and (6) scrollwork.

Many books produced during the Middle Ages were Bibles, parts of the Bible, or other religious books. There were also many nonreligious books produced, such as *bestiaries* (books about animals), romances, histories, legends, and writings by ancient Greeks and Romans.

Illustrated manuscripts

Some of the oldest existing illustrated manuscripts are copies of the Egyptian *Book of the Dead.* These scrolls date from the 18th Dynasty (1554-1304 B.C.). The Egyptians placed copies of the book, which contained prayers and hymns, in their tombs. Illustrated papyrus rolls were also common in ancient Greece and Rome.

After the codex form came into use, illustrations took on greater importance as they occupied more space on a page and were framed in decorative borders. Full-page illustrations appeared during the early Middle Ages. Portraits, which were derived from Greek, Roman, or Byzantine models, began to appear in the late 700's.

By the 1000's, the custom had developed of beginning some sections of a manuscript with a small picture called a *miniature.* Some miniatures were painted within the large initial letter, called a *historiated* initial, that began a manuscript section. Paul H. Mosher

Manzanita, *MAN zuh NEE tuh,* is the name of a group of evergreen shrubs that grow chiefly from British Columbia to California. The shrubs measure about 3 to 13 feet (0.9 to 4 meters) in height. Their leaves have smooth edges. White hairs cover the undersurface of the leaves. The small, bell-shaped flowers of manzanitas are pink or white. The fruit of manzanitas is red and fleshy. See also **Heath; Madroña.** James L. Luteyn

Scientific classification. Manzanitas belong to the genus Arctostaphylos in the heath family, Ericaceae.

Manzoni, *mahnd ZAW nee,* **Alessandro,** *ah lehs SAHN draw* (1785-1873), ranks as one of Italy's greatest novelists on the basis of his only novel, *The Betrothed.* This work, published in 1827 and again with revisions from 1840 to 1842, set the standard for modern Italian prose. *The Betrothed* is a long historical story set in Lombardy during the 1600's, when the province was ruled by Spain. It describes the adventures of two simple young silk weavers, Renzo and Lucia, whose marriage is prevented by a local tyrant, Don Rodrigo. The story is set against the background of larger historical events, including a war, a plague, and a famine.

Manzoni was born in Milan. At the age of 16, he began writing poetry, classical in style and patriotic in inspiration and content. Manzoni was baptized a Roman Catholic, but paid little attention to his faith until 1810. He then underwent a crisis that led him back to Catholicism. That crisis deeply influenced all his works. Manzoni wrote five religious *Sacred Hymns* (1812-1822) and an ode to Napoleon. In addition, Manzoni wrote two historical plays. Richard H. Lansing

Mao Tse-tung. See Mao Zedong.

Mao Zedong, *mow zeh dawng* (1893-1976), also spelled *Mao Tse-tung,* led the long struggle that made China a Communist nation in 1949. He then became China's ruler and one of the world's most powerful people. Mao controlled China's artistic, intellectual, military, industrial, and agricultural planning and policies.

After the Communist victory, Mao's face became familiar throughout the world. Pictures of him appeared everywhere in China. Young and old learned his slogans and studied his writings. His writings, particularly on guerrilla warfare and the role of peasants in Communist revolutions, were influential outside China. Mao also wrote poetry.

Eastfoto

Mao Zedong

His life. Mao was born to a peasant family in Shaoshan, a village in Hunan Province. He was still a student when the revolution of 1911-1912 overthrew the Manchu government and made China a republic. While he was employed briefly as a library worker at the National Beijing (Peking) University in 1918, Mao became attracted to the ideas of Communism. In 1921, Mao and 11 other people founded the Chinese Communist Party in Shanghai.

The Communists joined forces with Sun Yat-sen's *Kuomintang* (Nationalist Party) in the effort to unite China. But distrust between the Communists and Chiang Kai-shek, who became Nationalist leader after Sun's

death in 1925, soon led to warfare between the two groups. Mao and other Communist leaders led small bands to Jiangxi province in 1928. By 1931, that province had become Chiang's chief target. He began a series of "extermination campaigns" that nearly wiped out the Communists. In 1934, Mao led the Communists to Shaanxi (Shensi) province, in what is called the *Long March.* The 6,000-mile (9,700-kilometer) march lasted over a year and welded the survivors into a tightly knit group under Mao's leadership.

Japan had invaded Manchuria in 1931, and launched full-scale war against China in 1937. The Communists and Nationalists joined in an uneasy alliance until World War II ended in 1945. As Nationalist armies were driven inland during the war, Mao organized guerrilla warfare to spread Communism. By 1945, the Communists controlled areas populated by nearly 100 million Chinese. In 1946, fighting between Communists and Nationalists began in Manchuria. Communists gained control of China by October 1949, and Nationalists withdrew to Taiwan.

His leadership. Mao formed the Chinese into a tightly controlled society more quickly than most observers thought possible. After taking power, he made an alliance with the Soviets, who helped strengthen the Chinese army when Chinese forces aided North Korea in the Korean War (1950-1953).

After the war, Mao began programs to expand agricultural and industrial production. In 1958, a crash program called the *Great Leap Forward* failed. In the 1960's, a split developed between China and the Soviet Union. Mao ordered nuclear research that led to Chinese nuclear explosions in the 1960's.

In 1959, Mao gave up his title of chairman of the People's Republic. But he kept control of the country and of the Communist Party. By the 1960's, disputes between China and the Soviet Union had grown into a struggle for leadership of the Communist world. Mao considered himself the true interpreter of the principles of Communism. He believed that poor nations would inevitably revolt against richer nations. He also accused Soviet Communists of being soft toward the United States.

In the mid-1960's, China suffered a series of diplomatic defeats. To maintain revolutionary enthusiasm, Mao campaigned against so-called *revisionists,* who favored economic changes. In the early 1970's, China improved relations with the United States and other Western nations. Mao died in September 1976, after a long illness.

After Mao's death, Chinese leaders reversed many of his policies and ended the emphasis on his personality. They looked to Japan, the United States, and European countries for help in modernizing China's industry, agriculture, science, and armed forces. These goals were called the *Four Modernizations.* Arif Dirlik

Maori, *MAH oh ree,* are a Polynesian people of New Zealand. They were the first people to live in what is now that country. Today, they make up about 14 percent of New Zealand's population.

Many scholars believe the Maori began to migrate to New Zealand over 1,000 years ago. According to Maori tradition, however, they began arriving more than 1,800 years ago. The Maori made a living by fishing and hunting and eventually also by farming. By the 1700's, all of New Zealand was under Maori control. Individual Maori belong to one or more of the various Maori groups, though most no longer live in their group's traditional territory.

Europeans started arriving in New Zealand in the late 1700's. In 1840, the Maori and Britain signed the Treaty of Waitangi. It gave Britain the right to govern New Zealand, and the British the right to live there. It guaranteed the Maori ownership and control of all their lands, forests, fish, and waters. It also granted them all the rights and privileges of British citizens.

The early British immigrants did not respect the treaty and by 1900 had taken almost everything from the Maori. In the early 1900's, a group of young, university-educated Maori in New Zealand's Parliament started changing the way Maori were treated. In 1975, Parliament set up a tribunal to investigate violations of the Treaty of Waitangi. The tribunal has recommended the return of much land and other resources to the Maori.

On the whole, Maori are poorer than other New Zealanders. Most live in cities. Many return to their ancestral territories for birthdays, weddings, and funerals, or to help make decisions affecting their group. These events occur on *marae* (pronounced *muh RY),* traditional Maori meeting places. There, they pass down their oral history, arts, laws, technology, and other cultural traditions. The Maori speak English, and some speak the Maori language as well. Through the years, many have married people of European ancestry. Margaret Mutu

Maps have many uses. The girl on the left is consulting a world map to locate different countries. The driver on the right is using an in-vehicle navigation system to find the route to his destination.

Map

Map is an image that represents a geographic area in a way that helps people find places or understand the area's features. Many maps show places or conditions on earth. Maps may also depict other planets, the moon, or the position of stars in space.

We use maps to locate places, measure distances, plan trips, and find our way. Pilots of ships and airplanes use maps to navigate. City planners and engineers use maps to decide where to put new buildings or roads. Maps also help us understand such patterns as where people live, how ocean currents flow, or how much rain falls. Maps may also offer clues about conditions beneath the earth's surface. For example, geologists use maps to help find oil, gas, and other resources.

Making or studying maps is called *cartography.* A person who creates maps or knows a great deal about them is a *cartographer.* To design maps, cartographers use lines, colors, shapes, and other symbols. These symbols stand for such features as roads, rivers, forests, or cities.

A cartographer decides which features a map should show by considering how people will use the map. Because maps are much smaller than the area they represent, the features on a map are greatly reduced in size. For example, 1 inch (2.5 centimeters) on a map might represent a distance of 100 miles (160 kilometers) on the earth's surface. A tiny circle might represent a large city.

Because the earth is round, the best way to represent it is on a round map called a *globe.* A globe shows the location and shape of geographic areas exactly as they are on earth. But most maps are flat because, unlike globes, flat maps are easy to carry and to print in books.

Flat maps, however, are not completely correct. Representing the round earth on a flat surface requires stretching some areas and shrinking others. This stretching and shrinking is called *distortion.* Cartographers use mathematical methods called *projections* to make the earth look flat. Every type of projection distorts distances. Other features, such as land shapes or areas, may also be distorted. But each projection is useful in some important ways. For example, the Mercator projection exaggerates the size of areas near the North and South poles. But navigators have used Mercator projections for centuries because a path in any direction can be drawn as a straight line on these maps.

People probably made rough maps even before they began to use written language some 5,500 years ago. Over the centuries, maps became more accurate as people explored the world and developed improved ways to make maps. During the 1900's, people began to use aircraft and spacecraft to observe the earth and other heavenly bodies. These observations enabled people to create more accurate maps than ever before.

In the late 1900's, cartographers began to make most maps using computers. One of the most powerful new cartographic tools is a *geographic information system.* Such a system consists of computers, computer programs, and extremely large amounts of information. The information, which is stored as computer code, can include measurements or photographs taken from land, sea, or space. Cartographers can use such a system to produce many different maps from the stored data.

Personal computers have increased the ways in which map users can consult or obtain maps. Many programs for making maps are available for such computers. Large amounts of data and many maps are stored on a type of computer disc called a CD-ROM (*C*ompact *D*isc *R*ead-*O*nly *M*emory). These discs enable people to choose exactly the area they want to view, then print a map. Many maps are also available on the Internet. The Internet is a huge computer network over which governments,

Judy M. Olson, the contributor of this article, is Professor of Geography at Michigan State University and the author of numerous articles on maps and mapmaking.

individuals, businesses, and universities exchange information. Users can print Internet maps after they transfer them over telephone lines to their personal computers.

Types of maps

Cartographers create many types of maps for a variety of purposes. Some common types are (1) *general reference maps,* (2) *navigation maps,* (3) *thematic maps,* and (4) *inventory maps.*

General reference maps show the names and locations of many kinds of natural or constructed features. Such maps may include mountains, plains, bodies of water, roads, cities, and many other features. The main purpose of general reference maps is to help people find and identify places. Maps in atlases are general reference maps that show large areas of the earth. *Topographic maps* are general reference maps that show the details and heights of land features in a small area.

Some general reference maps show an extremely small area, such as the roads and house lots in one part of a city, in great detail. These maps, called *plats,* may be used as legal documents for such purposes as selling property. *Political maps* show the boundaries of units of government, such as counties, states, and countries.

Navigation maps, also called *mobility maps,* show people how to find their way from one place to another on land, on water, or in the air. Navigation maps for ships or airplanes are called *charts.*

Road maps are the most familiar navigation maps. These maps show different types of roads, including interstate highways, smaller local highways, and scenic routes. They also show the cities, towns, parks, and other sites connected by these roads. Travelers use road maps to plan trips and follow lengthy routes.

Street maps are like road maps but show a much smaller area in much greater detail. People use street maps to find particular addresses and to plan and follow short routes. Both road maps and street maps are among the types of maps available on CD-ROM's.

In-vehicle navigation systems create maps to guide drivers of moving vehicles. These systems constantly track a vehicle's location by using signals from a group of space satellites called the Global Positioning System. A computer in the vehicle combines the position data with stored street map data and produces maps of the route to a destination. The maps change as the vehicle

Types of maps

Some of the most familiar kinds of maps include (1) general reference maps, (2) mobility maps, (3) thematic maps, and (4) inventory maps. An example of each is shown at the right.

A general reference map helps people find and identify many different features. This example includes both geographical and political features.

A mobility map, such as a road map, helps people find their way from one place to another.

A thematic map, such as a population density map, shows the distribution pattern for a particular feature. In this map, darker colors indicate more populated areas.

An inventory map shows the exact location of specific features. The example at the far right locates vineyards, where grapes are grown.

General reference map

WORLD BOOK maps

moves. Some in-vehicle systems show the map on a small screen. Other systems produce spoken directions.

Transit maps show the routes traveled by buses, trains, subways, and other types of public transportation. Transit maps also show where people can board public vehicles and make connections between routes.

Aeronautical charts are used to navigate airplanes. Depending on their level of certification, pilots use *Visual Flight Rules* (VFR) or *Instrument Flight Rules* (IFR) charts. VFR charts show landmarks that pilots can see as they fly, such as roads, bridges, and towns. VFR maps also show airports and indicate the heights of mountains and other obstacles. IFR charts are designed for radio navigation. These charts show the location of transmitters of high-frequency radio signals. Pilots use these signals to determine their position and plot their course.

Some airplanes are equipped with computer systems that produce *heads-up display maps.* These maps are projected near eye level where the pilot can see them without looking down.

Nautical charts are used to navigate ships and boats. Nautical charts show water depths, lighthouses, buoys, islands, and such dangers as coral reefs and underwater mountains. These charts also locate sources of radio signals that crews use to plot their course and position.

Thematic maps show how a particular feature, such as population, rainfall, or a natural resource, is distributed over an area. These maps are used to study overall patterns—for example, how the average yearly rainfall varies from one part of Canada to another.

Many thematic maps express quantities by means of colors or symbols. For example, the *Population density* map in *World Book's* China article uses several shades of orange to show how heavily settled an area is.

Some thematic maps express quantities by using lines called *isolines* or *isograms* that connect areas of equal value. Some specific types of isolines have special names. On a weather map, for example, isolines called *isobars* connect places that have the same air pressure. Isolines called *isotherms* are used to indicate areas of common temperature. On topographic maps, *contour lines* show areas that are the same height.

Thematic maps may also use variations in size or shape to express quantities. A map of the international petroleum trade might indicate large exports of oil with thick arrows and small exports with thin arrows.

Inventory maps, like thematic maps, focus on a specific feature. But unlike thematic maps, which show only the distribution pattern of a feature, inventory maps provide the exact location of each featured item. For example, an inventory map might show every source of air pollution in a community, every school in a district, or every campsite in a park.

Reading a map

Using a map requires certain skills. To read a map, it is necessary to understand *map legends, scale,* a *north arrow, geographic grids,* and *map indexes.*

Map legends list and explain the symbols and colors used on a map. Some symbols resemble the features they represent. For example, a small tree might stand for a forest, an orchard, or a state park. But many symbols have little resemblance to the features they represent, as when a circle stands for a city. The same symbol may represent different features on different maps. For example, a triangle might represent a mobile home park on one map and an eagle's nest on another. Such differences make it important to read the map legend to find out what each symbol means on a particular map.

Scale shows the mathematical relationship by which distances on a map reduce actual distances on earth. Many maps illustrate scale by marking off distances on a straight line. Each mark shows how distance on the line corresponds to miles, kilometers, or other units of measurement on earth. Other maps state the scale in words and figures. Such a scale might appear as *1 inch: 16 miles.* In this relationship, 1 inch (2.5 centimeters) on the map represents a distance of 16 miles (26 kilometers).

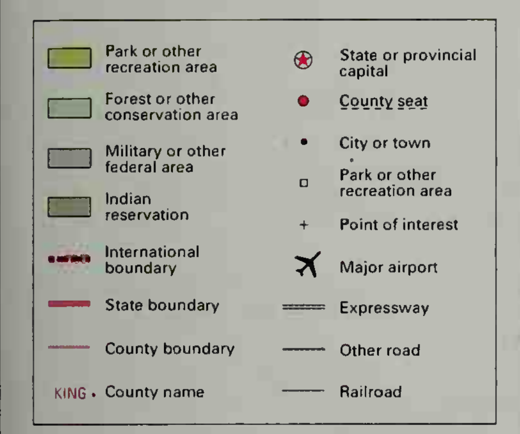
Representative fractions are also used to show scale. Such a fraction indicates the number of distance units on earth represented by one unit on the map. In the example above, where the scale is 1 inch: 16 miles, the representative fraction would be 1:1,000,000 or $\frac{1}{1,000,000}$ because there are 1,000,000 inches in 16 miles. The relationship remains the same for inches, centimeters, miles, kilometers, or any other units of measurement.

Scale varies widely, depending on the size of the area a map represents. A *small-scale* map greatly reduces distances on earth to show a large area in limited detail. Each distance unit on a small-scale map represents a large number of units on earth. These maps are called *small-scale* because their representative fractions are small. The large number of distance units represented on earth goes into the denominator, making the value of the fraction small. For example, on a map showing a nation's highway system, the scale might be 1:12,672,000, in which 1 inch represents 200 miles (322 kilometers).

A *large-scale* map shows a small area in great detail. These maps are called *large-scale* because their representative fractions are large. Each distance unit represents a relatively small number of units on earth. The small number of units makes the denominator of the representative fraction relatively small and the fraction's value relatively large. For example, a city street map might have a scale of 1:31,680, in which 1 inch represents $\frac{1}{2}$ mile (0.8 kilometer).

A north arrow shows the direction of north on a map. The arrow often has the letter *N* or the word *North* written over it. For an example of a north arrow, see the *Political map* in *World Book's* Minnesota article. Maps without a north arrow usually show north at the top of the map or include a geographic grid to orient the user.

Geographic grids are networks of imaginary lines that help us find and describe places on earth. These grids are commonly shown on maps. The most common grid is called a *graticule.* This grid divides the globe using lines called *parallels* that show north-south position and lines called *meridians* that show east-west position.



Parallels are circles around the globe that measure *latitude.* Latitude describes position north or south in *degrees,* a mathematical measurement applied to circles and angles. The equator is the parallel that lies at zero degrees (written 0°), exactly halfway between the North Pole and the South Pole. The North Pole has a latitude of 90° north, and the South Pole has a latitude of 90° south. Every point on earth that lies north of the equator has a latitude between 0° and 90° north. Every point south of the equator lies between 0° and 90° south.

How to read a map

This map shows a small area of the state of Washington and the province of British Columbia. The map is specially designed to demonstrate how to read map legends, map indexes, and map scales.

Map legends

Map legends explain what the symbols and colors on a map represent. The white ovals have been added to the map to point out some of the features that are explained in the legend.

Map indexes

A map index helps locate places on a map. In this example, the Potlatch index entry is followed by the letter *F* and number *6*. This information tells us that Potlatch is found on the map at the right where row F and column 6 cross.

Map scales

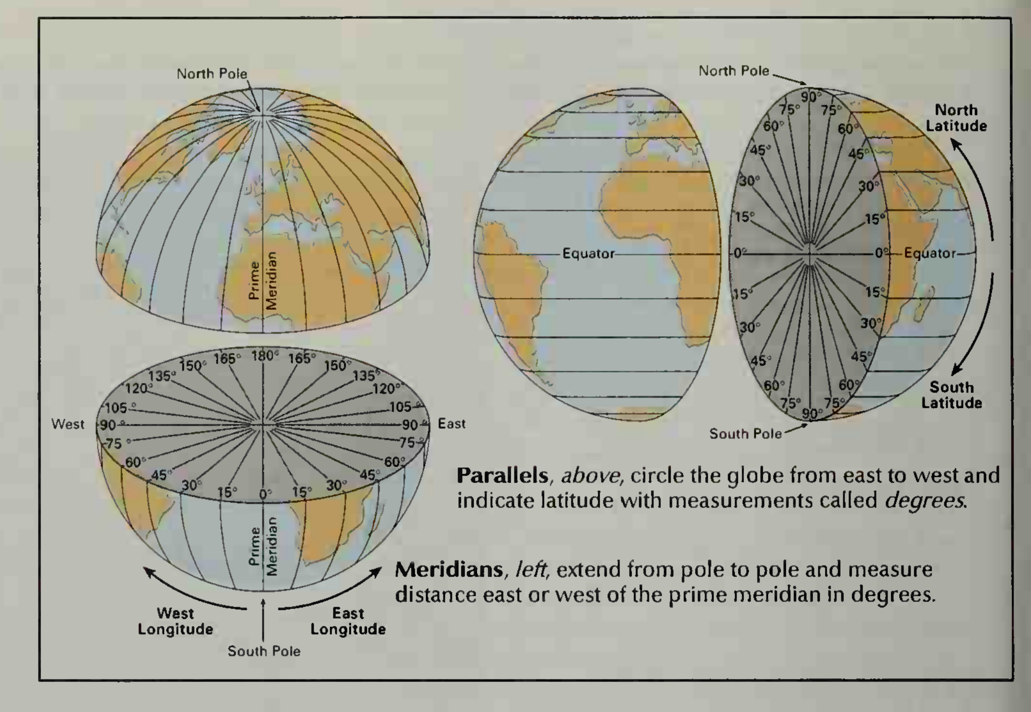
The scale at right—1:2,500,000—means that 1 unit of distance on this map equals 2,500,000 units of distance on earth. For example, 1 inch on the map equals 2,500,000 inches (about 40 miles or 63 kilometers) on earth.

WORLD BOOK map

Meridians extend from the North Pole to the South Pole, forming half-circles around the globe. Meridians, also measured in degrees, indicate *longitude* (east-west position). By international agreement, mapmakers place the 0° meridian, also called the *prime meridian,* on a line that passes through Greenwich (pronounced *GREHN ihj),* England, near London. The meridian in the Pacific Ocean that forms the other half of the prime meridian's circle lies at 180°. Longitude measurements range from 0° to 180° east and from 0° to 180° west.

If we know the latitude and longitude of a place, the graticule enables us to find that place on a map. Longitude and latitude measurements can be used to pinpoint any place on earth. For example, only one place—New Orleans, Louisiana, in the United States—lies exactly at 30° north and 90° west.

Map indexes list the features shown on a map in alphabetical order and provide an aid to locating the features. In many atlases, each index entry lists a feature's latitude, longitude, and map number. People can use the latitude and longitude to find the feature on that map.



Many maps of small areas, such as street maps, are divided into horizontal rows and vertical columns. The rows and columns are labeled with letters and numbers. Each feature in the map index is followed by a letter and number corresponding to one row and one column on the map. That feature can be found in the small section of the map where that row and column cross.

Map projections

A *map projection* is any of a number of mathematical methods that cartographers use to produce a flat map of

Geographic grids

Geographic grids are networks of imaginary lines on maps that help people find and describe locations. These illustrations show the most common geographic grid, the *graticule.* The graticule divides the earth using east-west lines called *parallels* and north-south lines known as *meridians.* Parallels indicate *latitude*—that is, distance north and south of the equator. Meridians show *longitude*—that is, east-west position.

Parallels, *above,* circle the globe from east to west and indicate latitude with measurements called *degrees.*

Meridians, *left,* extend from pole to pole and measure distance east or west of the prime meridian in degrees.

WORLD BOOK maps

the round earth. Creating a map projection can be imagined as having two steps. The first step is mapping the earth on a globe of a chosen scale. The round globe can exactly represent the round earth, with shapes of features and distances shown accurately.

The second step involves choosing a mathematical approach that, in effect, peels the surface off the globe and flattens it. This flattening always involves *distortion*—that is, stretching the surface in some areas and shrinking or tearing it in others. Different types of projections produce predictable inaccuracies in shapes, distances, or relative sizes of features. Distortion is most significant on maps of the whole earth or large areas of it.

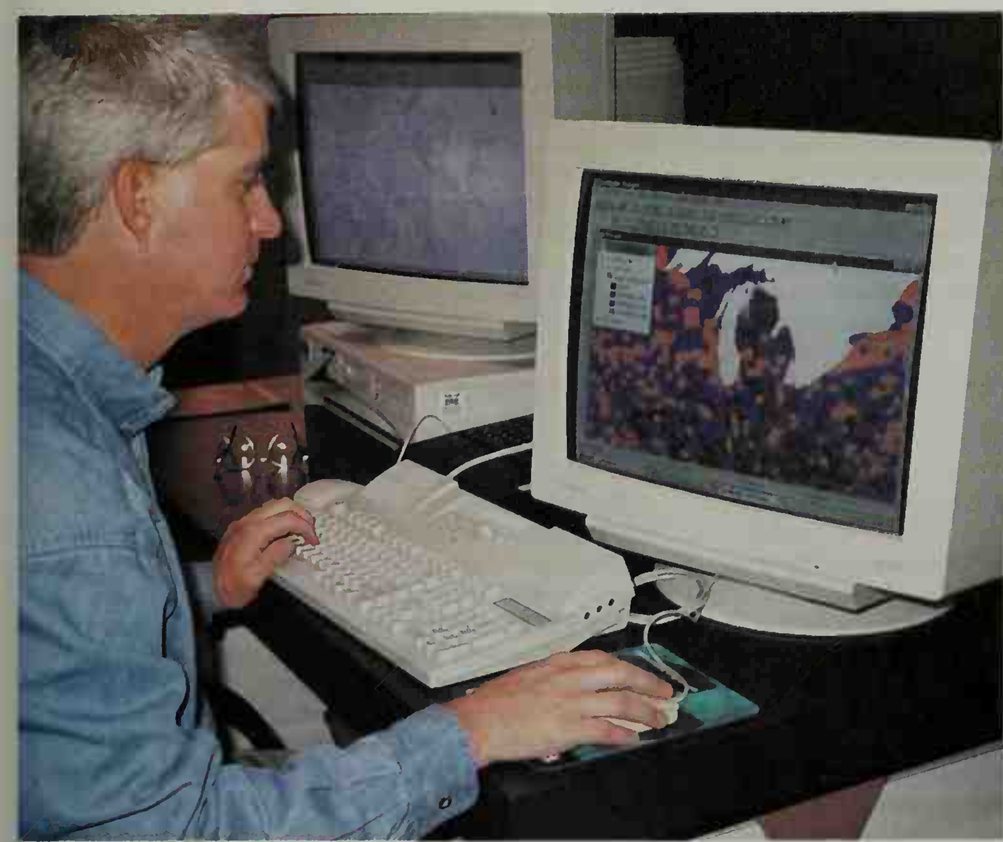
No single projection is best for all purposes. Cartographers decide which projection to use by considering the ways in which a particular map needs to be accurate. Computers enable cartographers to choose from among a large number of projections. For a discussion of some major map projections and their advantages and disadvantages, see the special feature on *Map projections* in this article.

How maps are made

Cartographers transform a wide variety of information into useful, attractive maps. In general, mapmaking follows these steps: (1) observation and measurement, (2) database development, (3) planning and graphic design, (4) production and reproduction, and (5) revision.

Observation and measurement. Cartographers observe and measure geographic features to collect fundamental information called *base data.* Base data were originally obtained chiefly by means of measurements performed on earth. For example, specialists called *surveyors* work out locations and boundaries of places by measuring distances, angles, and heights. After aircraft came into use in the early 1900's, aerial photographs became an increasingly important source of base data. Since the mid-1900's, spacecraft have provided another valuable source of data. For example, the Global Positioning System of satellites produces signals that can be used to calculate exact locations on earth. Other satellites record and send back images of the earth.

Base data may be used to create large-scale *topographic maps* that show a small area in great detail. Cartographers produce maps of larger areas by *compilation mapping.* Compilation mapping combines selected information—for example, political boundaries—from several smaller, highly detailed maps. During compilation, cartographers may also include statistical data, such as population distribution, rainfall averages, or tax rates.



Database development. Base data and statistical data are generally stored electronically in a collection of computer records called a *database.* In the United States, the U.S. National Imagery and Mapping Agency, the U.S. Geological Survey, and the U.S. Census Bureau maintain some of the largest databases of geographic information.

Much of this geographic information is available free for use by other government agencies, private companies, or individuals. For example, companies may add specialized information to make the databases more useful. Other companies may extract smaller databases from the larger ones. These revised databases may be a suitable size for in-vehicle navigation systems or map CD-ROM's for home computers.

Planning and graphic design. In planning a map, a cartographer considers how the map will be used. Knowing the map's purpose helps a mapmaker choose the best projection and scale for the task and decide which features to highlight or leave out.

A cartographer must also consider a map's *graphic design*—that is, its overall style and appearance. Symbols, colors, and lettering styles are all important parts of graphic design. Good graphic design helps a map communicate information effectively. In many cases, a graphic artist helps a cartographer design a map.

Production and reproduction. Maps may be drawn with hand or mechanical methods. But producing maps from databases requires computers. Some of the most powerful computer tools are *geographic information*

Intergraph Corporation

Mapmakers use computers for making many maps. This picture shows an arrangement of computer hardware and software called a *geographic information system* (GIS). A GIS enables cartographers to create any desired map from vast amounts of stored data.

systems, mapping programs, and *computer-aided design programs.*

A geographic information system (GIS) includes a computer to process information, a monitor that displays maps as they are created, and printing equipment. The most important part of a GIS is the *software* (sets of computer instructions, also called *programs).* GIS software enables cartographers to work with databases to extract the information needed for a particular map. The monitor constantly displays the map as its design progresses. Cartographers can experiment to develop the best map by adding or removing information, overlaying one map on another, or rotating the map.

A mapping program provides a more limited means of working with databases than does a GIS. Mapping programs have limited capabilities for adding or removing information, and users generally cannot overlay one map on top of another. Cartographers use mapping programs chiefly to create thematic maps.

A computer-aided design (CAD) program enables users to draw maps one symbol at a time. Cartographers use CAD programs to create maps that are not produced from databases. CAD programs are also useful for putting finishing touches on maps created using a GIS or mapping program.

Computers enable cartographers to print one or more copies of a finished map. A cartographer can print a small number of copies on an ordinary computer printer or on special printers that give superior color reproduction. Some systems control instruments called *plotters* that draw maps with pen and ink. If a large number of copies are needed, a cartographer may use a computer-aided design program to produce a series of images on plastic sheets or film. One sheet or piece of film is prepared for each ink color in a design. The images are then transferred to thin metal plates that are used to print multiple copies of the map.

Different steps are needed to produce maps that have a raised surface, such as *raised relief maps.* These maps are molded from plastics or other materials to produce elevations that represent hills and mountains. Another type of raised map is a *tactual map,* which has raised symbols that blind people can read by touch. Some tactual maps are created by photocopying a printed map onto a special material. When this material is exposed to bright light, cells in dark areas of the design swell and burst to produce raised images.

Revision. Our earth changes constantly as a result of geographic and political events. For example, changes may occur in the population of cities, the shape of coastlines, or the area of forests. Databases must be updated and maps must be revised to reflect these changes. Aerial photographs often provide new data for revisions.

History

Ancient maps. The oldest existing map appears on a clay tablet made in Babylonia (now part of Iraq) before 2000 B.C. This ancient map shows settlements, waterways, and mountains. The Babylonians had a lasting influence on mapmaking. They developed the system of dividing a circle into 360 degrees. We use this system to measure latitude and longitude.

The Egyptians made maps before 1000 B.C. They developed geometric techniques of surveying, probably to remap property boundaries each year after the Nile flooded its banks.

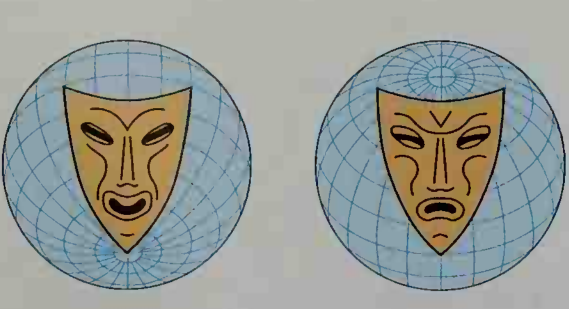
The Greeks made great advances in geometry and surveying, and they developed systems of map projections. They also thought deeply about the size and shape of the earth. The Greek mathematician Eratosthenes

calculated the circumference of the earth with remarkable accuracy in the 200's B.C.

One of the most influential cartographers of ancient times was Ptolemy, a Greek astronomer and geographer who worked in Alexandria, Egypt, about A.D. 150. Ptolemy created *Geography*, an eight-volume guide to mapmaking that combined his own ideas, the work of other scholars, and travelers' reports. This work included instructions for making map projections and a list of about 8,000 places along with their latitude and longitude. Zhang Heng (Chang Heng), a Chinese astronomer who worked at about the same time as Ptolemy, developed one of the first geographic grid systems for maps.

Maps in the Middle Ages. During the Middle Ages, the period from about 400 to the late 1400's, progress in mapmaking occurred mainly in the Arab world and China. Ptolemy's *Geography* was translated into Arabic in the 800's. Ptolemy's ideas inspired Arab cartographers to determine the latitude and longitude of the many places visited by Arab soldiers and traders. Cartographers also collected geographic descriptions from the travelers. In the mid-1100's, the Arab cartographer al-Idrisi made a

A World Book special feature

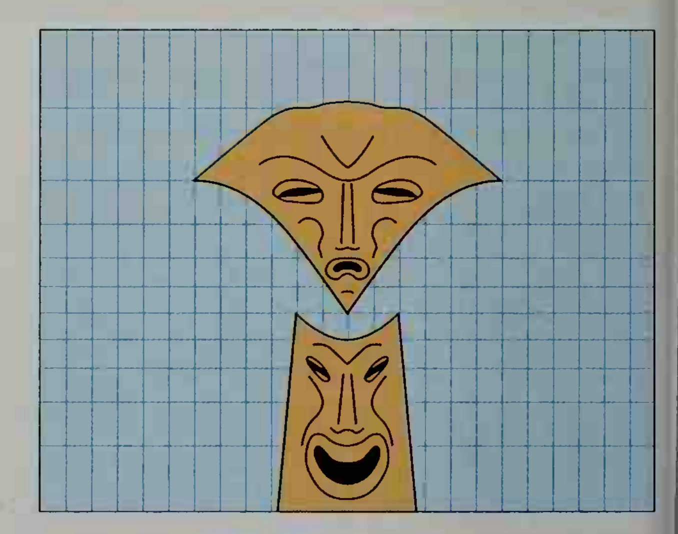


Map projections

Map projections are mathematical methods that cartographers use to represent the round earth on a flat map. The earth cannot be mathematically flattened without *distorting* its surface—that is, some areas must be shrunk and others must be stretched.

Familiar faces can demonstrate how a particular method of projection distorts the earth's surface. The following illustrations are based on the masks of Comedy and Tragedy used in ancient Greek plays. The undistorted masks are first sketched on a globe. Then the illustrations show what happens to these faces when they are transferred to a flat map. The illustrations show three important types of map projections: (1) the Mercator projection; (2) the Mollweide projection; and (3) the Robinson projection. Comparing each example with the original masks will help you see how different projections distort the features differently.

The earth is also mapped using each projection. Comparing these maps with a globe will help you see how these projections distort the earth's surface.



The undistorted globe. Tragedy's sad face is in the Northern Hemisphere. The center of this mask is at 45° north latitude, and its chin is on the equator. Comedy's smiling face is in the Southern Hemisphere, centered at 45° south latitude. This mask's chin is at the South Pole, and the upper tips of the mask are on the equator.

Undistorted view

The Mercator projection. Cartographers classify the Mercator projection as a *conformal projection*. In mathematical terms, a conformal projection shows the correct angles between directions at any point on a map. For example, at every point, north is always 90° from east. This mathematical property made the Mercator projection useful to early sailors because a path in any direction can be drawn as a straight line.

The main disadvantage of the Mercator projection is that geographic areas do not have correct size

Mercator projection

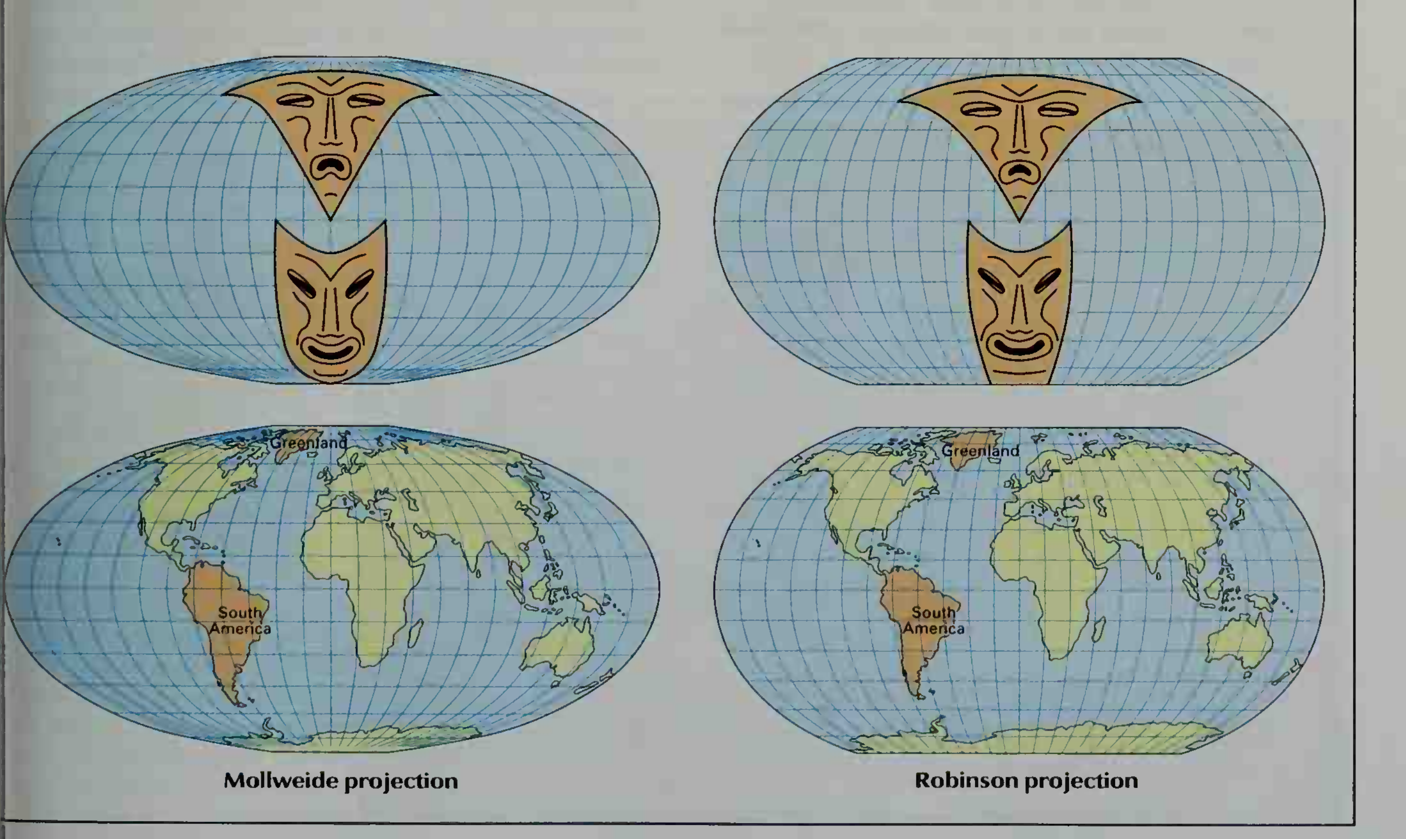
WORLD BOOK maps from projections prepared by John P. Snyder and Waldo R. Tobler for *Choosing a World Map*, a publication of the American Congress on Surveying and Mapping.

rectangular world map consisting of 70 sheets that contained much new information.

Also in the mid-1100's, an unknown Chinese cartographer made a carved stone map of China's land, coastline, rivers, and settlements. The accuracy of this map was not equaled until modern surveying techniques were developed. The earliest known printed map appeared in a Chinese encyclopedia about 1155, more than 300 years before printed maps were produced in Europe.

Little scientific progress occurred in European mapmaking during most of the Middle Ages. During the late 1200's and the 1300's, however, European mapmakers began producing *portolan charts,* a type of navigation map for sailors. Many of these charts showed coastlines of the Mediterranean and Black seas in remarkably accurate detail. Lines across each chart helped sailors determine compass directions.

Advances in European cartography. Three important developments in the 1400's contributed to progress in European cartography. First, Ptolemy's works were rediscovered and translated into Latin, the scientific language of the time. This rediscovery led to renewed



relationships to one another. For example, this projection makes areas near the North and South poles look much larger than they are on earth. Note how large Tragedy's forehead and Comedy's chin have grown on the Mercator projection. Areas near the equator also appear smaller than they are, as shown by Tragedy's tiny mouth. On the Mercator projection of the earth, Greenland appears larger than South America. In reality, South America is more than eight times larger than Greenland.

The Mollweide projection. Cartographers classify the Mollweide projection as an *equal area projection,* also called an *equivalent projection.* The main advantage of this type of projection is that areas are the correct size in relation to one another. Note how Greenland looks considerably smaller than South America on the Mollweide projection.

One disadvantage of the Mollweide projection is that some surface areas are the wrong shape. For example, note the outline of the Tragedy mask on the undistorted globe view. Now look at this shape on the cartoon projection. See also how both Comedy's and Tragedy's faces are lengthened on this projection.

The Robinson projection. The Robinson projection is an example of a *compromise projection.* A compromise projection tries to balance the different types of distortions that appear on conformal and equal area maps. For example, size relationships are shown much more accurately on the Robinson than they are on the Mercator and other conformal projections. But size relationships are not quite as accurate as they are on the Mollweide and other equal area projections.

On the other hand, shapes are considerably more accurate on the Robinson projection than they are on the Mollweide projection. In 1988, the National Geographic Society, a prominent educational and scientific organization, adopted the Robinson projection for its standard world map.

Mollweide projection

Robinson projection

interest in Ptolemy's methods of map projection and of locating places systematically. Second, the invention of the printing press in Europe in the mid-1400's made maps more widely available. Many identical copies could be produced by printing maps rather than by copying them by hand. Third, an age of worldwide exploration began in the late 1400's. The great voyages of discovery increased knowledge of the world and stimulated interest in mapmaking.

By the late 1400's, educated Europeans had accepted the idea that the world is round. In 1492, the year that the Italian navigator Christopher Columbus reached the Americas, a German merchant and navigator named Martin Behaim produced a globe. This globe represented the world as Europeans knew it before Columbus's voyage. Behaim's globe did not include the Americas, and it showed the Atlantic Ocean as much smaller than that ocean actually is. Mapmakers began including the Americas on maps by the early 1500's. The name *America* first appeared on a map produced in 1507 by a German cartographer, Martin Waldseemüller.

In 1569, Flemish geographer Gerardus Mercator created the first map based on his Mercator projection. This projection was of great value to sailors because a path in any direction appears as a straight line. The first collection of maps designed specifically to be combined into an atlas was produced by the Flemish mapmaker Abraham Ortelius in 1570.

Scientific activity during the 1500's, 1600's, and 1700's resulted in new instruments and techniques that made measurements of location and elevation more accurate. In the late 1600's, Giovanni Domenico Cassini, an astronomer at the Paris Observatory, began a project to produce an accurate topographic map of all of France. The last few of the map's 182 sheets were completed more than 100 years later under the direction of Cassini's great-grandson, Jean-Dominique Cassini.

In 1686, the English astronomer Edmond Halley developed what is considered the first weather map. This map showed the *trade winds,* part of earth's vast system of winds that were of great importance to early sailors. Around 1700, Halley also created a map of the earth's magnetic field. This accomplishment was the first published map that used isolines to connect points of equal value. In the mid-1700's, English clockmaker John Harrison built the first timepiece able to keep accurate time under the severe conditions at sea. This timepiece enabled sailors to measure their longitude with much greater precision than before.

Harvard Semitic Museum © The President and Fellows of Harvard College

The oldest known map is a clay tablet made in Iraq before 2000 B.C. It shows settlements, waterways, and mountains.

Mapping the Americas. During the 1600's and 1700's, the colonization of the Americas by Europeans created a need for many new maps. The Spaniards surveyed and mapped the lands under their control. In 1612, English adventurer Captain John Smith drew an

From Ptolemy's *Geography,* published in Ulm by Leinhart Holle, 1482, Library of Congress

An early map of the world appeared in a 1482 edition of Ptolemy's eight-volume *Geography.* Ptolemy was a Greek geographer and astronomer who lived about A.D. 150. Scholars are not sure if this map was made by Ptolemy himself or by cartographers who rediscovered his work after it had been lost for many centuries.

influential map of Chesapeake Bay. Smith also made the first English map of New England. During the early 1600's, the French explorer Samuel de Champlain mapped the region from what is now Maryland to the St. Lawrence River.

Surveying—that is, determining the location and boundaries of places by measuring angles, distances, and heights—was an important activity in the American Colonies. Surveyors Joshua Fry and Peter Jefferson produced a map of the region from Virginia to the Great Lakes in 1751. In 1755, John Mitchell, a Virginia colonist, compiled his *Map of the British and French Dominions in America.* A copy of this map was used to mark the boundaries of the United States after the Revolutionary War in America ended in 1783.

As pioneers moved westward during the 1800's, explorers and army engineers mapped trails and surveyed government lands. The U.S. government established two agencies with responsibility for detailed, large-scale mapping. The Survey of the Coast—now the National Ocean Survey—was founded in 1807. The U.S. Geological Survey was officially created in 1879.

Development of thematic and inventory mapping. By the 1800's, it had become common for governments to collect population data by taking censuses. Cartographers then created thematic maps to display and study this wealth of new information. British cartographer Henry D. Harness advanced thematic mapping with several maps of Ireland published in 1837. These maps used tones to indicate population density, black circles of different sizes to show the population of cities, and lines of different thickness to represent traffic flow.

In 1855, John Snow, an English physician, dramatically demonstrated the value of inventory mapping for scientific research. On a map of London neighborhoods, Snow used a dot to represent each person who had died of cholera during an epidemic. A large number of dots clustered around a water pump on Broad Street. This pattern helped identify water dispensed from that pump as the source of the epidemic infection raging through the city.

Mapmaking and modern technology. During the first half of the 1900's, improvements in printing and photography made it cheaper and easier to produce maps. As a result, maps became more readily available and widely used. Development of airplanes and automobiles in the early 1900's created a need for aeronautical charts and road maps.

Airplanes also made possible aerial photography, the first *remote sensing* technology. Remote sensing involves gathering data with a device that is far away from the object being studied. Although aerial photography remains widely used, remote sensing is now also performed with electronic sensors, such as radar and infrared imaging systems, that reveal features invisible to the human eye.

Many remote sensing devices are carried in spacecraft. Spacecraft have provided an increasingly important source of geographic information since the mid-1900's. Space exploration has given mapmaking a variety of new technologies, such as the Global Positioning System of satellites. It has also expanded mapping of moons, other planets, and the vast reaches of space.

Remote sensing data can now be stored along with data from other sources in huge databases. Cartographers can use geographic information systems and mapping programs to create any desired map from such databases. During the late 1900's, computer equipment replaced hand and mechanical instruments as the most powerful and important cartographic tools.

Grant Heilman

The sugar maple ranks as one of the most valuable trees of North America. Its sweet sap is used in making maple syrup, and its hard wood makes excellent lumber.

E. R. Degginger

The silver maple is named for the silvery-white underside of its leaves.

Maple is any of about 120 species of broadleaf trees and shrubs common in forests of the Northern Hemisphere. Most maples grow in regions with climates that are neither very cold nor very warm. About two-thirds of all maple species are native to China. Other species are native to other parts of Asia, Europe, North America, and northern Africa.

Maples are easy to recognize because their leaves grow in pairs on opposite sides of the branch, and each leaf has several lobes. No other North American tree has opposite, lobed leaves. Nearly all maples lose their leaves in the autumn. In numerous species of maples, the leaves turn bright orange, red, or yellow before they drop off.

E. R. Degginger

Jerome Wexler, APF

The Norway maple, *above,* is an important timber tree in northern Europe. It was introduced into North America, where it has become popular as a street tree. In spring, the tree has bright-yellow blossoms, *left.*

Maples flower in the spring, either before or at the same time the leaves appear. Most maples bear male and female flowers on the same tree. Maple seeds, sometimes called *keys,* grow in pairs and have flat, thin wings that make them whirl and float in the wind as they fall. Breezes can carry the seeds far from the parent tree, thus helping maples spread to new areas.

Maples are an important source of lumber. Some species have very hard, strong wood. Manufacturers use it to make furniture and musical instruments. The sap of certain maple species is used to make maple syrup. People also plant maples as shade trees.

North American maples

Fourteen species are native to North America. They grow mostly in the eastern half of the continent.

Sugar maple is one of the most common trees in the broadleaf forests of southeastern Canada and the northeastern quarter of the United States. This tree typically grows 75 to 100 feet (23 to 30 meters) tall and measures 2 to 3 feet (60 to 90 centimeters) in diameter at its base. However, it may reach a height of 135 feet (41 meters) tall and a diameter of 5 to 6 feet (1.5 to 1.8 meters). The sugar maple is most common in areas that are neither swampy nor very dry.

Sugar maple wood is the hardest and strongest maple wood. It polishes well and is widely used for furniture, cabinets, and violins and other musical instruments. It is also used for making bowling alleys. Some sugar maple wood has an unusual grain pattern that makes it particularly beautiful and valuable. This wood, called *curly maple* or *bird's eye maple,* is used in fine furniture and stringed musical instruments.

People also value the sugar maple for its sweet, flavorful sap. The sap rises in the trunks in the spring. Syrup producers collect the sap from pipes driven into the tree trunks. They then boil the sap down to make maple syrup and maple sugar. Maple syrup production is a multimillion dollar industry in New England and southern Canada. See **Maple syrup**.

Red maple is common in eastern and midwestern forests of the United States and in southeastern Canada. This tree thrives in rich, moist woods; on rocky ridges with thin, dry soil; and in swampy areas that are flooded for part of the year. Most red maples grow 70 to 90 feet (21 to 27 meters) tall.

The red maple has red twigs. In the fall, its leaves usually turn red. People sometimes plant the red maple as a shade tree in yards and along streets because it is colorful in both spring and fall and grows well in most soils. Furniture makers sometimes use the wood of the red maple.

Silver maple is common along rivers and streams in much of the eastern and midwestern parts of the United States and in southeastern Canada. Unlike most trees, the silver maple produces seeds in the spring instead of in the fall. Botanists believe this characteristic developed as an adaptation to growing near rivers that flood in the spring. Such flooding washes away plants and soil, leaving bare areas of ground. Many silver maple seeds fall on these bare areas and begin growing without competition from other plants.

The silver maple was once popular as an ornamental tree because it grows fast. But people seldom plant it today because its branches break off easily in storms and the leaves are not colorful in the fall. The silver maple produces brittle wood with limited economic value.

Boxelder, sometimes called *ashleaf maple,* is the most widespread maple in North America. It often grows along streams and swamps throughout much of the United States and Canada. It is also found in parts of Mexico and Central America. The boxelder has *compound leaves*—that is, each leaf consists of several leaflets. The male and female flowers of the species grow on different trees. Female trees grow in wetter sites, and male trees grow in drier places.

In the past, landscapers often used the boxelder as a street tree because it grows fast when young. However, they rarely plant it today because its branches split off easily. Boxelders produce soft, weak wood that has little economic value. See **Boxelder**.

Charles E. Mohr, NAS — Jerome Wexler, NAS

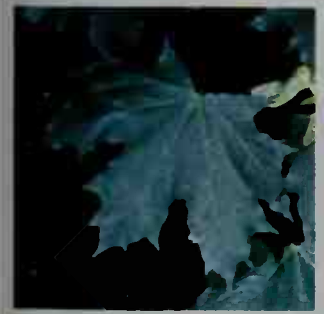
The fruit of maple trees consists of a pair of winged seeds, *left.* The wind carries the seeds away from the tree, and the seeds take root and start to grow, *right.*

Bigleaf maple is the only tree-sized maple found in the Pacific Northwest. It often grows in open areas and near lowland streams. It is also found growing under the giant evergreen trees of the Pacific Coast rain forest. Bigleaf maple leaves may measure 6 to 12 inches (15 to 30 centimeters) across. The wood is sometimes used for furniture and musical instruments.

Other maples

Several species of maples native to Europe have been planted widely in North America. The *Norway maple* averages about the same size as the red maple. It is an important timber tree in northern Europe. Landscapers use the Norway maple as a street tree in North America because it tolerates pollution well. The *sycamore maple* ranks as an important timber tree in central and southern Europe. It, too, is sometimes planted as a street tree in North America.

Certain species of maples native to Asia are widely planted as ornamental shrubs. They include the *Japanese maple* and the *fullmoon maple.* Some cultivated kinds of these trees have red or bronze-colored leaves.



Scientific classification. Maples make up the genus *Acer* in the maple family, Aceraceae. The scientific name for the sugar maple is *Acer saccharum.* The red maple is *A. rubrum;* the silver maple, *A. saccharinum;* the boxelder, *A. negundo;* the bigleaf maple, *A. macrophyllum.* The Norway maple is *A. platanoides;* the sycamore maple, *A. pseudoplatanus;* the Japanese maple, *A. palmatum;* and the fullmoon maple, *A. japonicum.*

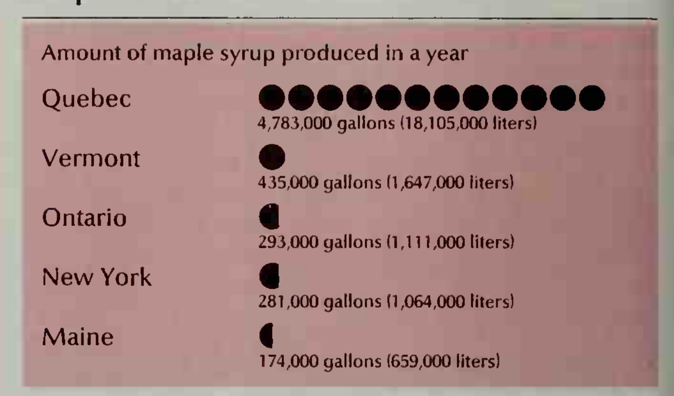
Maple, Flowering. See Flowering maple.

Maple syrup is a sweet, flavorful liquid obtained from the sap of certain maple trees. The *sugar maple* tree ranks as the chief source of this delicious food product. Vermont leads the states of the United States in maple syrup production. But the Canadian province of Quebec produces more maple syrup than all the states together.

Maple sap is a colorless, watery solution that contains a type of sugar called *sucrose* and various amino acids and minerals. The U.S. and Canadian governments require that maple syrup consist of at least 65 $\frac{1}{2}$ percent of these solids. It usually takes 30 to 40 gallons (114 to 151 liters) of sap to make 1 gallon (3.8 liters) of maple syrup.

The typical maple flavors and *amber* (golden brown) colors develop during processing. Syrup is often classified by color, ranging from the palest amber, called *light amber* or *fancy,* to the darkest amber, called *commercial.* All maple syrups have the same food value, but they differ in flavor. In general, the lighter the syrup, the more delicate the taste.



People pour pure maple syrup on pancakes, waffles, and other foods. Because it is costly to produce, pure maple syrup is expensive. Many people use maple-flavored syrups that cost less. Most of these contain a small amount of maple syrup, which is blended with other sweeteners, such as cane-sugar syrup and corn syrup.

Production. Syrup producers begin to collect sap from maple trees in early spring, when freezing nights are followed by warm days. The daily rise and fall of temperature causes the sap to start flowing. This period, known as the *sugaring* season, lasts from three to six weeks or until buds fall off the maple trees.

Syrup producers use one of two methods to collect the sap. In the older method, a producer drills one or more holes into a tree and drives a metal spout into each hole. The sap runs through the spout into a bucket that hangs from the spout. The producer empties the buckets into a large barrel, which is taken by sled or wagon to a building called a *sugarhouse.*

In the more modern method, a producer inserts plastic spouts into holes drilled in the trees. The sap runs through tubes connected to the spouts and into a pipeline system that carries sap to the sugarhouse. A properly managed pipeline system yields more sap than the bucket method. A pipeline system also requires less time and labor.

In the sugarhouse, workers boil the sap in a long, shallow pan called an *evaporator.* As the sap boils, water evaporates until pure maple syrup remains. The maple color and flavor also develop during this process. Producers remove the syrup from the evaporator when its temperature reaches 219 °F (104 °C). They may boil the sap beyond the syrup stage to make maple butter, maple taffy, or maple sugar.

History. Indians who lived near the Great Lakes and the St. Lawrence River produced maple sugar and syrup long before white explorers came to North America. Early French and English explorers wrote of the "sweet water" that the Indians drew from trees and heated to make the maple products.

During the 1700's and 1800's, maple sugar ranked as an important food item. People in maple sugar producing areas traded it for various foods and services. Gradually, white cane sugar became less expensive than maple sugar. By the late 1800's, cane sugar had replaced

maple sugar for most purposes. At about that time, food manufacturers developed maple-flavored syrups.

Today, artificial maple flavorings are used in certain foods. But these flavorings do not taste exactly like pure maple syrup. Many people choose pure maple syrup for its natural ingredients and delicate taste. Claude Tardif

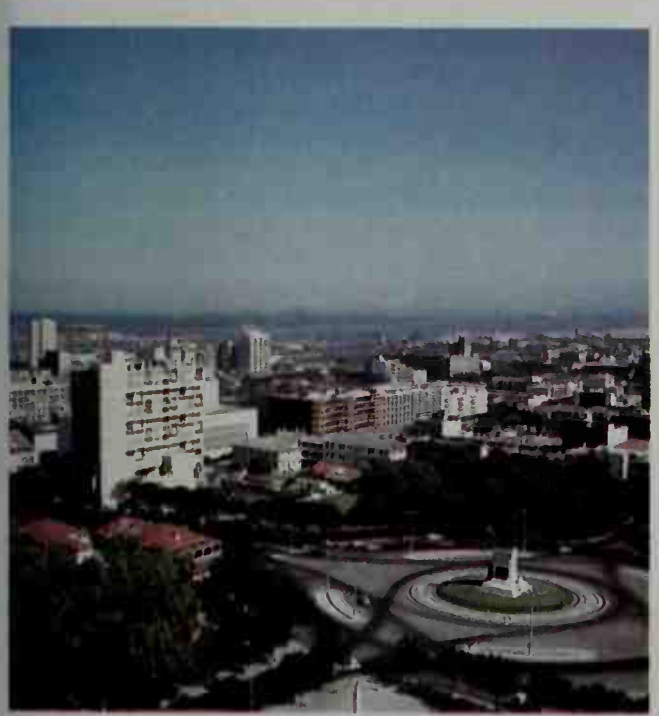
Maputo, *muh POOT oh* (pop. 1,006,765; met. area pop. 1,551,457), is the capital and largest city of Mozambique. It has an excellent harbor and is the chief port of Mozambique and several nearby countries. It is located in southern Mozambique on Delagoa Bay, an inlet of the Indian Ocean. For the location of Maputo, see **Mozambique** (map).

The Portuguese founded the city about 1780 and named it Lourenço Marques. The city became the major white settlement in Mozambique, but most of the whites left in 1975 after Mozambique gained independence from Portugal. In 1976, the city's name was changed to Maputo.

The main sections of Maputo have wide, tree-lined streets and large beaches. The fortress of Nossa Senhora da Conceiçáo, built in 1871, is a famous landmark. Food processing is the city's most important industry.
John D. Metzler



Maquis, *mah KEE,* were French patriots who fought against the German occupation of France during World War II (1939-1945). Most members of the Maquis were young French men, but women also served, usually as carriers of messages or supplies. Volunteers from other parts of Europe also joined the Maquis.

Maquis is a Corsican word for the tough vegetation of southern France. The Maquis started as small guerrilla bands in the hills and forests of France. They ambushed German army convoys, derailed trains, and sabotaged German military production. The Allies parachuted ammunition to the resistance fighters. The Maquis suffered many losses, but they played a key role in liberating France. Today, monuments throughout rural France honor the Maquis. H. R. Kedward

Mar del Plata, *MAHR dehl PLAHT uh* (pop. 532,845), is one of the most popular resort cities in Argentina. Its pleasant climate and beautiful beaches draw more than 2 million vacationers each year. The city lies in eastern Argentina and borders the Atlantic Ocean. For location, see **Argentina** (political map).

Modern, high-rise apartment buildings and hotels line Mar del Plata's beaches. The city has a huge casino, fashionable shops, and plazas filled with trees and flowers. Tourism is Mar del Plata's chief industry. Other important industries include fishing and fish processing.

Mar del Plata was founded in 1874. It became a favor-

ite resort of wealthy Argentines during the late 1800's. Middle- and lower-income people began vacationing there during the mid-1900's. During the 1970's, the city's permanent population grew sharply, rising by more than 100,000. Richard W. Wilkie

Marabou, *MAIR uh boo,* is one of the largest birds in the stork family. The marabou lives throughout Africa. Two closely related species, the *greater adjutant* and the *lesser adjutant,* are found in India and Southeast Asia. See **Adjutant.**

The marabou has long legs and stands up to 5 feet (1.5 meters) tall. The wings and upper body are slate-gray or black, and the underparts are white. The bird has beautiful, soft, white tail feathers, which are also called *marabou.* Manufacturers once used these feathers to make scarves and to trim hats and gowns. The head and neck of the marabou are almost featherless. A long pouch of reddish skin hangs down from the neck. A marabou can inflate this pouch with air, which may help it attract other marabous as mates.

C. Haagner, Bruce Coleman Inc.

Marabous have a long, pointed bill and a nearly bald head and neck. These large storks are found in Africa. They measure up to 5 feet (1.5 meters) tall.

Marabous feed largely on the remains of dead animals. They also eat live prey, including frogs, fish, reptiles, and locusts. Marabous nest in colonies. They build platformlike nests high in trees or on rocks and lay two or three white eggs. James J. Dinsmore

Scientific classification. The marabou belongs to the stork family, Ciconiidae. Its scientific name is *Leptoptilos crumeniferus.*

Marajó, *MAH rah ZHAW,* is a Brazilian island. It covers 15,444 square miles (40,000 square kilometers) between the *estuaries* (river mouths) of the Amazon and Pará rivers in northeastern South America (see **Brazil** [terrain map]). About 270,000 people live on the island.

Marajó is a plain just above sea level. Much of the plain is flooded during the six-month rainy season. The vast grasslands that cover most of the island make good pasture for water buffalo. Forests fringe the shores and banks of waterways. Rubber trees are scattered through these forests. J. H. Galloway

Maraschino cherry, *MAR uh SKEE noh* or *MAR uh SHEE noh,* is a preserved cherry. Maraschino cherries are used to decorate and add flavor to desserts and beverages. The cherries received their name because they were originally preserved in *maraschino,* a liqueur distilled from the fermented juice of the marasca cherry. Today, the cherries are artificially colored, flavored, and preserved. Several varieties of cherries are used. They are picked before they have fully ripened, and are pitted by a machine. Margaret McWilliams

Marat, *mah RAH,* **Jean-Paul,** *zhahn pawl* (1743-1793), was one of the most radical leaders of the French Revolution (1789-1799). He helped increase the violence of the period by demanding death for all opponents of the revolution.

Marat was born May 24, 1743, in Boudry, Switzerland, near Neuchâtel. He became a doctor and a writer. During the 1770's and 1780's, Marat wrote books on electricity, heat, light, and physiology, as well as on law and political theory. The French Academy of Sciences rejected Marat's chief ideas, and Marat believed that officials of

the academy had cooperated to keep him from winning the recognition he deserved.

Marat strongly supported the French Revolution, which began in 1789. He believed it would improve conditions, especially for the poor. Marat founded a newspaper, *L'Ami du Peuple (The Friend of the People)*. The paper violently criticized those who opposed the revolution.

Portrait by Joseph Boze, Musee Carnavalet, Paris (Bulloz)

Jean-Paul Marat

In August 1792, the people of Paris put King Louis XVI and his family in prison. Marat called for death for those who continued to support the king. Indirectly, he contributed to the violent mood of the public that led to the massacres in Paris in September. That month, bands of revolutionaries broke into the city's prisons and killed over 1,000 prisoners, including priests and aristocratic supporters of the king.

Later in September, Marat was elected to the National Convention, a body that was writing a new constitution for France. He joined a group called the *Jacobins,* who demanded the king's execution.

Marat soon became the main target of moderate members of the convention, known as *Girondists.* They accused Marat of plotting against them and brought him to trial. He was acquitted and, in turn, called for the expulsion of Girondist leaders from the convention. They were expelled and then arrested in June 1793. In July, Marat was stabbed to death by Charlotte Corday, an aristocrat who supported the Girondists.

Isser Woloch

Marathon, *MAIR uh thahn,* a coastal plain in Greece, was the site of one of the most important battles in the history of Western civilization. There, in 490 B.C., a Greek army defeated an invading army of Persians and saved Greece from becoming part of the Persian Empire. Marathon lies about 25 miles (40 kilometers) northeast of Athens.

Causes of the battle. In 507 B.C., the Athenians asked King Darius I of Persia to become their ally against Sparta, a powerful city-state in southern Greece. To form the alliance, representatives of Athens promised Athenian obedience to Darius. The Athenian government later rejected the agreement, but Darius continued to consider himself the rightful ruler of Athens.

Beginning in 499 B.C., Greeks living under Persian rule in Asia Minor (now Turkey) rebelled against Darius. The Athenians sent soldiers and 20 ships to aid the rebels. Then the Greek forces attacked and burned Sardis, a city that served as Darius's capital in Asia Minor. Darius vowed that he would take revenge on the Athenians by conquering and burning Athens.

The battle. In 490 B.C., Darius sent his nephew Artaphernes and Datis, one of his generals, with an army and a fleet of about 200 ships to conquer Athens. The Persians first destroyed Eretria, a city on the Greek island of Euboea, and then sailed for Marathon. The Athenian general Miltiades positioned the Athenian troops on the inland edge of the plain. The Persians occupied the seaward edge. Both armies waited several days. The Persians awaited a signal that Athenians allied to them had weakened Athens by starting a civil war in the city. Meanwhile, the Athenian army waited for expected help from Sparta. But only about 600 soldiers from Plataea, a city near Athens, joined the Athenians at Marathon.

A few days later, the Persian leaders, hoping that civil war had broken out in Athens, loaded part of their forces on ships. The Persians on the ships prepared to sail to Athens and attack the city. Seeing their chance for a victory, the Athenian forces charged the army of Persians that remained on the plain. The Greeks surrounded and thoroughly defeated the Persians at Marathon.

The Persians, not worried about the defeat at Marathon, sailed for Athens. They reached Phaleron—Athens's harbor—a few days later. There, the Persians found that civil war had not broken out. They also learned that the Athenian army at Marathon had reached Athens before the Persian ships did. As a result, the Persians returned to Persia.

According to tradition, Miltiades sent the runner Pheidippides from Marathon to Athens with news of the Athenian victory. Pheidippides raced the 25 miles (40 kilometers) to Athens at top speed, delivered his message, and fell to the ground, dead. Today, the word *marathon* refers to a foot race of 26 miles 385 yards (42.2 kilometers) or of similar length. Jack Martin Balcer

Maravich, Pete (1947-1988), was one of the greatest scorers in basketball history. His sensational shooting earned him the nickname "Pistol Pete." Maravich's brilliant passing and behind-the-back dribbling also made him one of the game's most exciting players.

Maravich, a guard, played at Louisiana State University from 1967 to 1970. He led all college players in scoring during each of his three varsity seasons. His total of 3,667 points and average of 44.2 points a game are National Collegiate Athletic Association (NCAA) career records.

Maravich played for 10 seasons in the National Basketball Association (NBA) with four teams, beginning with the 1970-71 season. He averaged 24.2 points a game in the NBA and led the league in scoring during the 1976-1977 season.

Peter Press Maravich was born on June 22, 1947, in Aliquippa, Pennsylvania. He died at the age of 40 from heart failure due to a natural heart defect. Bob Logan

Marble is a rock widely used in buildings, monuments, and sculptures. It consists chiefly of calcite or dolomite, or a combination of these carbonate minerals. Marble is a type of *metamorphic rock* formed from limestone (see **Metamorphic rock**).

Most marble of commercial value was formed in the *Paleozoic Era* or earlier in *Precambrian Time* (see **Earth** [(table: Outline of Earth's history)]). Marble is found in many countries, including Belgium, France, Greece, India, Italy, Spain, and the United Kingdom. South American nations also have large marble deposits. In the United States, Georgia produces the most marble. Other chief marble-producing states include Alabama, Colorado, Montana, Tennessee, Texas, and Vermont.

Field Museum of Natural History, Chicago (WORLD BOOK photo)

Marble occurs in many colors. It consists chiefly of calcite or dolomite, or a combination of these minerals. Impurities in the minerals produce the variations in color.

WORLD BOOK photo

The beauty of marble makes it an attractive building stone. The desk and walls shown above are made of marble.

Georgia Marble Company

Marble is mined in quarries such as this one in Georgia. Special mining equipment is used to cut the marble into blocks and remove it from the quarry.

Properties. Marble is formed from limestone by heat and pressure in the earth's crust. These forces cause the limestone to change in texture and makeup. This process is called *recrystallization.* Fossilized materials in the limestone, along with its original carbonate minerals, recrystallize and form large, coarse grains of calcite.

Impurities present in the limestone during recrystallization affect the mineral composition of the marble that forms. At relatively low temperatures, silica impurities in the carbonate minerals form masses of chert or crystals of quartz. At higher temperatures, the silica reacts with the carbonates to produce diopside and forsterite. At extremely high temperatures, rarer calcium minerals, such as larnite, monticellite, and rankinite, form in the marble. If water is present, serpentine, talc, and certain other hydrous minerals may be produced. The presence of iron, alumina, and silica may result in the formation of hematite and magnetite. In some cases, all these impurities may react to form garnets, hornblendes, and pyroxenes.

The minerals that result from impurities give marble a wide variety of colors. The purest calcite marble is white. Marble containing hematite has a reddish color. Marble that has limonite is yellow, and marble with serpentine is green.

Marble does not split easily into sheets of equal size and must be mined carefully. The rock may shatter if explosives are used. Blocks of marble are mined with *channeling machines,* which cut grooves and holes in the rock. Miners outline a block of marble with rows of grooves and holes. They then drive wedges into the openings and separate the block from the surrounding rock. The blocks are cut with saws to the desired shape and size.

Uses. Marble has long been highly valued for its beauty, strength, and resistance to fire and erosion. The ancient Greeks used marble in many buildings and statues. The Italian artist Michelangelo used marble from Carrara, Italy, in a number of sculptures. Marble from Tennessee was used in parts of the National Gallery of Art in Washington, D.C. The Lincoln Memorial, also in Washington, was built of marble from Alabama, Colorado, and Georgia.

Extremely pure calcite marble is used for most statues. This kind of marble is *translucent*—that is, light penetrates a short distance below the surface of the marble before it is reflected. Large blocks of colored marble are used for columns, floors, and other parts of buildings. Smaller pieces of such marble are crushed or finely ground and used as abrasives in soaps and other products. Crushed or ground marble is also used in paving roads and in manufacturing roofing materials and soil treatment products. Robert W. Charles

Marbles is a children's game played with small balls, usually made of glass. Each ball is called a marble. There are many types of marbles games. Most games are played outdoors on a level surface. Marbles can be an

organized sport, but it is most popular as a form of recreation.

Players shoot marbles by balancing a large marble called a *shooter* between the thumb and index finger. With the thumb, the player flicks the shooter toward one or more smaller marbles, called *object marbles*. Usually, players must *knuckle down* when shooting—that is, they must keep at least one knuckle on the ground as they shoot.

Marbles of various materials and colors have their own slang names. For example, glass marbles with colored swirls are known as *glassies*. Steel ball bearings used as marbles are called *steelies*.

In the United States, a game called *ringer* is played in tournaments. In ringer, players try to knock object marbles out of a circle 10 feet (3 meters) in diameter. Before play begins, a referee arranges 13 object marbles into the shape of a cross in the circle's center. Players start their turns by knuckling down outside the circle. From

Jerry Brule, Marble Collectors Unlimited

Kinds of marbles include modern marbles made by machine, *left*, and antique handmade marbles, *right*.

there, a player must knock at least one object marble from the circle, and the player's shooter must remain in the circle. If successful, a player continues to shoot from wherever the shooter comes to rest. A turn ends when a player fails to knock out a marble or the shooter leaves the circle. The next player then takes a turn. The first to knock seven object marbles out of the circle wins.

Marbles made of baked clay have been found in prehistoric caves. The ancient Romans played games of marbles 2,000 years ago. Rachel Gallagher

Marbury v. Madison marked the first time the United States Supreme Court declared a federal law unconstitutional. This 1803 case is one of the most important decisions in history. Chief Justice John Marshall wrote the opinion for the court. He held that it was the duty of the judicial branch to determine what the law is. His opinion established the power of *judicial review*—that is, the court's authority to declare laws unconstitutional.

In 1801, President John Adams appointed William Marbury justice of the peace in the District of Columbia. But Thomas Jefferson had defeated Adams in the presidential election in November 1800. Jefferson was sworn in before Marbury took office, and James Madison, the new secretary of state, withheld Marbury's appointment. Marbury asked the Supreme Court, under Section 13 of the Judiciary Act of 1789, to force Madison to grant the appointment. But the court refused to rule on the appointment because Section 13 gave the Supreme Court powers not provided by the Constitution. As a result, the court declared Section 13 unconstitutional. Gregg Ivers

Marceau, *mahr SOH,* **Marcel** (1923-), is the best known of modern mime artists. Marceau gained fame for his performances as Bip, a white-faced clown who wears a striped jersey and a battered top hat with a rose.

Marceau was born on March 23, 1923, in Strasbourg, France. His real name was Marcel Mangel. He became fascinated by mime at age 5, when he watched motion pictures starring silent comedian Charlie Chaplin. Marceau enrolled in the School of Dramatic Art of the Sarah Bernhardt Theatre in Paris where he studied with actor and director Charles Dullin. He also studied mime under the great French actor and mime Étienne Decroux.

Marceau first performed as Bip in 1947. In 1948, he organized the Company of Mime of Marcel Marceau, which he directed until 1960. He established the School of Mime of Paris in 1978. Marceau has created about 100 pantomimes, many of which have been made into short films. Don B. Wilmeth

See also **Pantomime** (picture).

Marcel, Gabriel (1889-1973), was a French philosopher. He was an unsystematic thinker who presented most of his philosophy in three philosophical diaries: *Metaphysical Journals* (1927), *Being and Having* (1935), and *Presence and Immortality* (1959). His philosophy consists of reflections on concrete human experiences such as love and fidelity. He believed human experience can be understood only by directly participating in it. Therefore, he tried not merely to observe but to relive these experiences in the course of his reflections. His other works include *Homo Viator* (1944), an analysis of hope; and *Man Against Society* (1951), an examination of the effects of technological society on the human personality.

Marcel was born on Dec. 7, 1889, in Paris. He became a Roman Catholic at 39. He is often classified as a Christian existentialist (see **Existentialism**). Ivan Soll

March is a highly rhythmic musical composition that is performed mainly to accompany marching. A march is intended to raise a military troop's morale, provide color and pageantry at sports events, or lend dignity to official ceremonies. Some ballets, operas, and classical instrumental works also include marches. Most marches have a main melody called a *march* and a contrasting part called a *trio*. The trio generally is quieter and more melodious than the march and is played in a different key.

There are various kinds of marches. Two of the most common kinds are the *military march* and the *ceremonial march*. Military marches have a quick tempo and are used to help large groups march in an orderly manner. The American bandmaster John Philip Sousa wrote many popular military marches. Ceremonial marches are slower than military marches and are played at serious events, such as coronations and school graduations. The English composer Sir Edward Elgar wrote five famous ceremonial marches that are called *Pomp and Circumstance*. Other types include *circus marches,* which have fast tempos, and *funeral marches,* which have the slowest tempos of all marches. R. M. Longyear

See also **Elgar, Sir Edward William; Sousa, John Philip; King, Karl.**

March is the third month of the year, according to the Gregorian calendar, which is used in most of the world today. It was the first month of the early Roman calendar. Later, the ancient Romans made January 1 the beginning of the year, and March became the third month. The Romans called this month *Martius* in honor of Mars, the Roman god of war. March has always had 31 days. Assassins killed the Roman emperor Julius Caesar on March 15, also known as the Ides of March, in 44 B.C.

The equinox occurs on March 19, 20, or 21. On this day, the sun shines directly on the equator, and the lengths of day and night are nearly equal all over the world. In the Northern Hemisphere, the equinox in March marks the start of spring and is often called the vernal (spring) equinox. In the Southern Hemisphere, the March equinox is the beginning of autumn. Equinox celebrations are widespread and varied. In Iran, Nowruz (Persian New Year) celebrations begin on the date of the March equinox and last for 13 days. Some people in other countries of central and southern Asia, including Afghanistan and Iraq, also celebrate the Persian New Year. Japanese Buddhists celebrate Higan on both the vernal equinox in March and the autumnal equinox in September. All businesses close for the celebrations. The Japanese use this time to honor their ancestors.

Hina-Matsuri, a Japanese doll festival for girls, occurs on March 3. On this day, girls display a set of dolls on a special stand in their homes. These dolls represent members of the royal court and are usually family heirlooms. People visit each other to admire the dolls.

March 17 is St. Patrick's Day. Parades and parties mark this date in the United States and other countries where Irish immigrants have settled. Many people wear green clothing and eat traditional Irish foods, such as corned beef and cabbage. In Ireland, the celebrations are usually more solemn and religious in nature.

Important March events

1 Ohio became the 17th U.S. state, 1803.
— Augustus Saint-Gaudens, American sculptor, born 1848.
— Nebraska became the 37th U.S. state, 1867.
2 Sam Houston, American political leader, born 1793.
— Bedřich Smetana, Czech composer, born 1824.
— Carl Schurz, American political leader, born 1829.
— Texas declared its independence from Mexico, 1836.
— Pope Pius XII born in 1876.
— Kurt Weill, German composer, born 1900.
— Mikhail Gorbachev, Soviet leader, born 1931.
3 Hina-Matsuri (Doll Festival, or Girls' Day), Japan.
— Missouri Compromise passed by U.S. Congress, 1820.
— George Pullman, American inventor and businessman, born 1831.
— Florida became the 27th U.S. state, 1845.
— Alexander Graham Bell, telephone inventor, born in Scotland in 1847.
— Russia signed the Treaty of Brest-Litovsk, 1918.
4 William Penn received grant of Pennsylvania, 1681.
— The first Congress under the U.S. Constitution met, 1789. This date was used as Inauguration Day until 1937.
— Vermont became the 14th U.S. state, 1791.
5 Gerardus Mercator, Flemish geographer, born 1512.
— British soldiers fired on rioters in Boston Massacre, 1770.
— Heitor Villa-Lobos, Brazilian composer, born 1887.
— Joseph Stalin, Soviet dictator, died 1953.
6 Ghana became independent in 1957.
— Michelangelo Buonarroti, Italian artist, born 1475.
— Elizabeth Barrett Browning, English poet, born 1806.
— Mexican general Santa Anna captured the Alamo, 1836.
— Ring Lardner, American humorist, born 1885.
7 Luther Burbank, American horticulturist, born 1849.
— Tomáš Masaryk, cofounder of Czechoslovakia, born 1850.
— Maurice Ravel, French composer, born 1875.
— Alexander Graham Bell, Scottish-born inventor, patented the telephone in 1876.
8 Oliver Wendell Holmes, Jr., American jurist, born 1841.
9 Amerigo Vespucci, Italian explorer, born 1454.
— The *Merrimack* (then called the *Virginia*) fought the *Monitor*, American Civil War, 1862.
10 Arthur Honegger, French composer, born 1892.
11 Torquato Tasso, Italian poet, born 1544.
12 Mauritius became independent in 1968.
— William Mackenzie, Canadian politician, born 1795.
— Sir John J. C. Abbott, prime minister of Canada, born 1821.
— Clement Studebaker, American manufacturer, born 1831.
— Gabriele d'Annunzio, Italian poet, born 1863.
— Juliette Gordon Low founded the Girl Scout movement in the United States, 1912.
— First transatlantic radio broadcast, 1925.
— Indian nationalist leader Mohandas Gandhi and his followers began the 24-day Dandi march to protest the British tax on salt, 1930.
— United States President Harry S. Truman announced the Truman Doctrine, 1947.
13 Joseph Priestley, English chemist, born 1733.
— Johann Wyss, Swiss author, born 1781.
14 Eli Whitney patented the cotton gin, 1794.
— Johann Strauss, Austrian composer, born 1804.
— Albert Einstein, German American physicist, born 1879.
15 Julius Caesar assassinated, 44 B.C.
— Andrew Jackson, seventh U.S. president, born 1767.
— Maine became the 23rd U.S. state, 1820.
— American Legion founded, 1919.
16 James Madison, fourth U.S. president, born 1751.
— Georg S. Ohm, German physicist, born 1787.
— United States Military Academy founded at West Point, New York, in 1802.

March birthstone—bloodstone

March flower—violet

March 5—Boston Massacre

March 6—Michelangelo born

The Jewish festival of Purim usually falls in March. It occurs on the 14th day of the Hebrew month of Adar. Purim marks Queen Esther's rescue of the Jews of Persia from a plot to kill them. Jewish people celebrate this holiday by reading the book of Esther in the Bible and with masquerade parties, giving to charity, and feasting.

Many countries, including China, Russia, the United Kingdom, and the United States, celebrate International Women's Day on March 8. This day honors women, especially working women. March is Women's History Month in the United States. It is a time to recognize women's achievements and contributions to society.

Flowers associated with March are the violet and the jonquil. The birthstones for this month are the bloodstone (a variety of chalcedony) and the aquamarine.

Carole S. Angell

Quotations

The stormy March has come at last,
With wind, and cloud, and changing skies;
I hear the rushing of the blast
That through the snowy valley flies.

William Cullen Bryant

I wonder if the sap is stirring yet,
If wintry birds are dreaming of a mate,
If frozen snowdrops feel as yet the sun,
And crocus fires are kindling one by one.

Christina Rossetti

The year's at the spring
And day's at the morn; ...
God's in His heaven—
All's right with the world!

Robert Browning

March, Peyton Conway, *PAY tuhn* (1864-1955), was chief of staff of the United States Army during World War I (1914-1918). He directed the operations that landed about 2 million American troops in France. March has been called the father of the modern U.S. Army. He combined the Regular Army, the National Guard, and the National Army divisions into a single force. He also reorganized the War Department, and built a small, well-organized army around a core of professional soldiers. March believed a small corps of trained officers could build a large, powerful army in an emergency.

March was born on Dec. 27, 1864, in Easton, Pennsylvania. He graduated from the U.S. Military Academy (West Point) in 1888 and fought in the Spanish-American War (1898). He retired from active service in 1921. He described his World War I experiences in *The Nation at War* (1932). He died on April 13, 1955. Maurice Matloff

March of Dimes Birth Defects Foundation is a health agency that supports research, education, and medical and social services for children and pregnant women. It is a leading authority on such issues as birth defects, low birth weight, infant mortality, and maternal drug and alcohol abuse.

President Franklin D. Roosevelt established the agency in 1938 to combat epidemic poliomyelitis, or polio. It was then called the National Foundation for Infantile Paralysis. It funded the development of the Salk and Sabin vaccines that help prevent polio. In 1958, the agency began working to prevent birth defects and changed its name to National Foundation—March of Dimes. March of Dimes referred to the dimes sent to the agency's annual fund-raising drive during Roosevelt's presidency. The agency took its present name in 1979.

The March of Dimes is supported by donations and assisted by volunteers. Headquarters are in White Plains, New York.

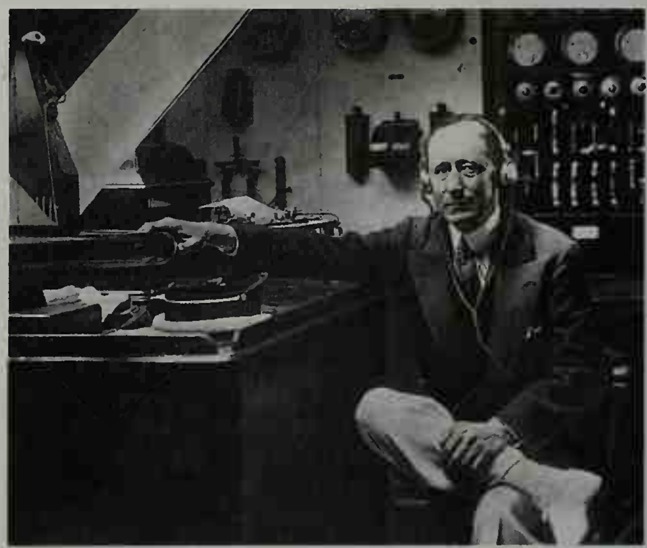
Critically reviewed by the March of Dimes Birth Defects Foundation

Marciano, *MAHR see AH noh,* **Rocky** (1923-1969), was the world heavyweight boxing champion from 1952 to 1956. He retired in 1956 after winning all of his 49 professional fights. Marciano won the title on Sept. 23, 1952, by knocking out Jersey Joe Walcott in the 13th round in Philadelphia. Eight months later, in his first title defense, Marciano knocked out Walcott in the first round. Marciano then successfully defended his title five more times. Marciano is considered one of the hardest punchers in boxing history. His victories include 43 knockouts, with 11 in the first round. In 1951, he ended the comeback of former world champion Joe Louis by knocking him out in the 8th round.

Marciano was born Rocco Marchegiano on Sept. 1, 1923, in Brockton, Massachusetts. He turned professional in 1947. Marciano died in the crash of a private airplane on Aug. 31, 1969. Bert Randolph Sugar

Marco Polo. See Polo, Marco.

Marconi, *mahr KOH nee,* **Guglielmo,** *goo LYEHL moh* (1874-1937), was an Italian inventor who popularized *wireless telegraphy,* or radio (see **Radio**). He was one of the first inventors to send telegraph signals through the air using radio waves. Telegraph signals previously had been transmitted through wires. Marconi shared the 1909 Nobel Prize in physics with Karl Ferdinand Braun of Germany, who had developed ways of increasing the range of radio transmissions.



Early life. Marconi was born on April 25, 1874, in Bologna, Italy. His father was a wealthy landowner. As a child, Guglielmo took a strong interest in science. After failing the University of Bologna entrance exam, he pursued his scientific studies on his own. Inspired by the German physicist Heinrich Hertz's work with electromagnetic waves, Marconi began experimenting with wireless telegraphy in 1894. Working in the attic of his father's estate, he transmitted signals across the room. Marconi later experimented outdoors. He found that when his transmitter and receiver were *grounded* (connected to earth), and when he increased the height of the antenna, he could greatly extend a signal's range.

The Italian government showed no interest in the young, unschooled inventor's work, so Marconi went to the United Kingdom. There, in 1896, he received his first patent on wireless. Marconi founded the Wireless Telegraph and Signal Company, Ltd., in London in 1897. In 1899, he sent a wireless message across the English Channel to France, and ships began using his system.

First transatlantic signal. On Dec. 12, 1901, Marconi and his staff sent the first wireless transatlantic communication. They transmitted the Morse code letter *s* from Poldhu, Cornwall, England, to St. John's, Newfoundland, now part of the Canadian province of Newfoundland and Labrador. Ships were soon using Marconi's equipment to communicate with each other and with the shore over hundreds of miles or kilometers. Marconi's equipment helped bring rescue ships for the sinking ocean liners *Republic* in 1909 and *Titanic* in 1912, saving many lives. These accidents led to laws requiring that all large passenger ships have wireless equipment.

After 1902, Marconi devoted more of his time to managing his companies, which by 1914 dominated the wireless industry in both the United Kingdom and the United States. In 1919, Marconi's American company became part of the Radio Corporation of America (RCA).

Short-wave radio. During the 1920's, Marconi turned his attention to short waves and microwaves. The existing commercial wireless equipment used long radio waves, which required large, powerful transmitters. But

Brown Bros.

Guglielmo Marconi centered his life around wireless telegraphy. In his yacht, *shown here,* Marconi experimented sending and receiving messages while crossing the Atlantic Ocean.

short-wave stations did not need such transmitters, and they cost less to build and operate. Short waves, unlike long waves, could be used as effectively during the day as at night. Marconi and his staff perfected the *beam system,* which used directional aerials and reflectors. This system made short-wave radio an efficient, reliable method of communication. Marconi's team also built the first microwave telephone system in 1932. Marconi died on July 26, 1937.

Marconi and Tesla. While Marconi was experimenting with wireless telegraphy, other prominent inventors were also working to develop the technology. One of these inventors was Nikola Tesla, an American from Austria-Hungary. By 1898, Tesla had developed high-voltage, high-frequency equipment to send signals between his laboratory and hotel in New York City. But while Tesla ambitiously planned to use his system to transmit electric power, Marconi concentrated on the profitable market of ship-to-shore communications.

In 1943, the Supreme Court of the United States invalidated many of Marconi's U.S. patents for radio communications equipment. It recognized that Tesla had patented a number of key radio inventions prior to Marconi. W. Bernard Carlson

Marcos, Ferdinand Edralin (1917-1989), served as president of the Philippines from 1965 to 1986. In 1973, the Philippines adopted a constitution that gave him broad powers as both president and prime minister. In 1978, Marcos took the title of prime minister while remaining as president. In 1981, he was replaced as prime minister, but he kept his broad powers. Marcos's political party was accused of widespread election fraud in 1986. He was forced to leave the country after widespread protests against him. Corazon Aquino, his main election opponent, became president. Marcos settled in Hawaii. See **Philippines** (The Marcos era).

In 1988, Marcos and his wife, Imelda, were indicted by the United States government. The indictment included charges that they had embezzled money from the Philippines and used it to purchase buildings in the United States. But after Marcos became seriously ill, the charges against him were dropped. He died in exile on Sept. 28, 1989. In 1990, a jury found Imelda not guilty. In 1991, Imelda returned to the Philippines to face civil and criminal charges there. She ran for president of the Philippines in 1992, but lost. She was convicted of corruption in 1993, but the Philippine Supreme Court overturned the conviction in 1999. From 1995 to 1998, she served in the Philippine House of Representatives.

Marcos was born in Sarrat on Sept. 11, 1917. While a law student at the University of the Philippines, he was convicted of murdering a man who had defeated his father in an election for the National Assembly. But the Supreme Court acquitted him. Marcos served in the Philippine House of Representatives from 1949 to 1959. He was elected to the Senate in 1959. Jean Grossholtz

Marcus Agrippa. See Agrippa, Marcus.

Marcus Aurelius, *aw REE lee uhs* (A.D. 121-180), was a Roman emperor and philosopher. He became a follower of Stoicism, a school of philosophy that originated in Greece about 300 B.C. Marcus wrote a series of thoughts that were collected and published as *Meditations.* This work is an intimate self-portrait and a classic of Stoic philosophy. See **Stoic philosophy.**

Marcus was born in Rome to a noble family on April 26, A.D. 121. Before Antoninus Pius became emperor in 138, he adopted Marcus and Lucius Verus. Marcus became emperor in 161 and named Lucius co-emperor. Marcus and Lucius ruled jointly until Lucius's death in 169. During much of Marcus's reign, the Roman Empire suffered from epidemics, revolts, and frequent wars along its frontiers. Marcus turned to Stoic philosophy for personal comfort. He died on March 17, 180.

Marcus accepted the Stoic belief that the world is ruled by a benevolent universal force. He was inspired by the Stoic belief in the harmony of natural and moral law that represented the divine spirit present in all things. Marcus believed that the soul did not survive after death, but instead was reabsorbed into the universe. He saw this reabsorption as a reason to accept death calmly. Marcus hated selfishness and taught himself to ignore or forgive offenses. Perhaps his noblest quality was his sense of responsibility to humanity and his belief that all people are citizens of the universe and should live for each other. Elaine Fantham

Mardi Gras, *MAHR dee GRAH,* is a lively, colorful celebration held on Shrove Tuesday, the day before Lent begins. The date of Mardi Gras depends on the date of Easter. Mardi Gras takes place at the end of a long carnival season that begins on January 6, or Twelfth Night. It is celebrated in many Roman Catholic countries and other communities. *Mardi Gras* means *fat Tuesday* in French. The term may have arisen in part from the custom of parading a fat ox through French towns and villages on Shrove Tuesday.

French colonists brought Mardi Gras to America in the early 1700's. It grew popular in New Orleans, Louisiana, and spread through the Southern States. Mardi Gras is a legal holiday in Alabama and Florida and in eight *parishes* (counties) of Louisiana.

The New Orleans celebration is the most famous. It attracts tourists from around the world. Parades begin the week before Mardi Gras. Societies called *krewes* organize and pay for the parades and other festivities. During the carnival season, the krewes give balls and parties. They parade in masks and fancy dress. A parade of floats and marching bands climaxes the carnival on Mardi Gras. Riders on the floats throw necklaces and coins called *doubloons* to onlookers. Biloxi, Mississippi, and Mobile, Alabama, also have Mardi Gras celebrations.

Mardi Gras goes back to an ancient Roman custom of merrymaking before a period of fast. In Germany, Mardi Gras is called *Fastnacht.* In England, it is called *Pancake Day* or *Pancake Tuesday.* Robert J. Myers

Marduk, *MAHR duk,* was the chief god of the ancient Babylonians. He was originally a god of only the city of Babylon. However, as Babylon grew to become the most powerful city in Mesopotamia, Marduk became the most important god. Marduk was called the "great lord, the lord of heaven and earth." His power was said

to lie in his wisdom, which he used to help good people and to punish the wicked. C. Scott Littleton

Mare. See Horse (Life history).

Marfan syndrome is a genetic disorder affecting the body's connective tissues. It is caused by a mutation in a gene called *FBN1* found on chromosome 15. The mutation leads to abnormal structure and function of a protein called *fibrillin* found in connective tissue. People with the syndrome have a tall thin body and distinctly long arms, legs, fingers, and toes. Loose-jointedness and abnormalities of the chest wall and back, called *scoliosis,* are common. Marfan syndrome affects 1 in every 5,000 to 10,000 people. A child of an affected parent has a 50 percent chance of inheriting the syndrome.

The most serious problem associated with Marfan syndrome is weakening of the heart and blood vessels, particularly the *aorta,* the main blood-carrying vessel from the heart. Rupture of the aorta is a leading cause of premature death among persons with Marfan syndrome. Eye problems, including lens dislocation, detached retina, and nearsightedness are also common.

A thorough evaluation is required to make the diagnosis of Marfan syndrome. With proper diagnosis, drug therapy, and surgery to strengthen the aorta, many people with Marfan syndrome can live a normal life span.

Alan C. Braverman

Margarine, also called *oleomargarine,* is a butterlike food made from vegetable oils or animal fats, or both. Many people cook with margarine and use it on bread and other foods. Many bakeries and other food manufacturers also use it.

In the United States, people use more than twice as much margarine as butter. Margarine usually costs less than butter, and it can be processed so that it has the same food value. It also contains a greater proportion of *polyunsaturated fatty acids* and much less of a fatty substance called *cholesterol.* Many doctors warn that too much cholesterol in the blood can lead to a heart attack. See **Fat** (Fats and disease).

How margarine is made. The U.S. government requires that margarine contain at least 80 percent fat. The fat must be *emulsified* (evenly distributed) in milk, water, or a type of milk made from soybeans. Margarine also must be fortified with vitamin A at a level equal to that in butter. Most margarine also contains butterlike flavoring, salt, vitamin D, and yellow coloring. Preservatives are added to prevent decay. One or more vegetable oils provide the fat content of most margarine. Soybean oil is the most commonly used oil. But processors also may use corn, cottonseed, palm, peanut, and safflower oils. Some margarine is made with animal fats.

To make margarine, manufacturers emulsify melted oils with milk or water and chill the resulting substance until it hardens. Most household margarine is made in sticks or is packaged in small tubs. Manufacturers also make large blocks of hard margarine for commercial bakeries, and fluid household margarine in plastic squeeze bottles.

History. Hippolyte Mege-Mouries, a French chemist, developed margarine in the late 1860's as a substitute for butter. He called it *oleomargarine* because its chief ingredients were beef fat, called *oleo,* and *margaric acid.* The product was introduced into the United States in the early 1870's. Almost immediately, U.S. dairy farmers protested that it would ruin the butter market. As a result, Congress put a tax on margarine in 1886 to discourage its sale. By the 1930's, many states had banned the sale of yellow-colored margarine. Such margarine was more popular than the natural white variety.

People bought margarine despite the restrictions, and criticism of the federal tax increased. Congress ended the tax in 1950. By 1967, all state bans on colored margarine had also ended. Margarine sales more than doubled from 1950 to 1970. Kay Franzen Jamieson

Margay, *MAHR gay,* is a wildcat that lives in Central and South America from northern Mexico to Bolivia and Brazil. Its reddish or grayish fur is thickly marked with black spots and streaks. Its tail is longer than the head and body. The margay is $2\frac{1}{2}$ to 4 feet (76 to 122 centimeters) long and weighs 10 to 20 pounds (4.5 to 9 kilograms). It resembles the *ocelot* (tiger cat) but is smaller, more slender, and has a longer tail (see **Ocelot**). The margay's name may have come from an Indian term for "little ocelot." Zoologists know little about its habits.

Jeff Foott, Bruce Coleman Ltd.

The margay is a wildcat that lives in Central and South America. Its markings are similar to those of the ocelot. The margay has a small head and a very long tail.

Scientific classification. The margay belongs to the cat family, Felidae. It is *Felis wiedii.* Elizabeth S. Frank

Margin in a stock exchange refers to funds that speculators deposit with their brokers to protect the brokers against loss. The deposit safeguards the brokers, in case speculators lose money after they have bought stocks. It must cover the difference between the selling price of the stocks and the amount the brokers can borrow from a bank, plus an amount to cover possible losses that might result from stocks quickly changing prices. In the United States, the Federal Reserve System sets the amount of margin required. Robert Sobel

Margrethe II, *mahr GRAY tuh* (1940-), is queen of Denmark. She succeeded her father, Frederik IX, upon his death in 1972.

Margrethe was born on April 16, 1940, in Copenhagen. Her full name is Margrethe Alexandrine Torhildur Ingrid. She became next in line for the throne in 1953, when the Danish Constitution was changed to enable women to rule. A lack of male heirs to the throne forced the change. Margrethe attended universities in Denmark, England, and France. She presided over the Danish Cabinet at formal functions when her father was ill.

During the 1960's, Margrethe traveled to Africa, the Far East, and the Middle East in connection with her interest in archaeology. In 1967, she married Henri de

Laborde de Monpezat, a French count, who became Prince Henrik of Denmark. They have two sons, Frederik, the crown prince, and Joachim. In addition to performing her royal functions, Margarethe is an artist and book illustrator. Her works have been exhibited publicly. Ulla Skovgaard Jensen

Maria Theresa (1717-1780) was Holy Roman empress, queen of Hungary and Bohemia, and archduchess of Austria. She was a powerful force in European affairs and one of the wisest and most able rulers in Austrian history. With the aid of her brilliant chancellor and foreign minister, Prince Kaunitz, she managed foreign affairs skillfully. Her economic reforms promoted the prosperity of her empire. She had 16 children. One daughter, Marie Antoinette, was queen of France (see **Marie Antoinette**).

Maria Theresa was born in Vienna. Her father, Emperor Charles VI, was the last male Habsburg (or Hapsburg) heir. In 1724, he announced publicly a decree, called a Pragmatic sanction, that had been issued privately in 1713. This decree allowed Maria Theresa to inherit his territories. The rulers of the principal states of Europe accepted the decree and promised not to attack Maria Theresa's lands (see **Pragmatic sanction**).

Charles VI died in 1740. Prussia was the first to attack in the War of the Austrian Succession and was soon joined by Bavaria, France, and Spain. They all claimed parts of Maria Theresa's territories in spite of their promises. At first, Sardinia and Saxony also opposed Maria Theresa. But they later joined the Netherlands and Britain in aiding Maria Theresa's forces in the war. In 1745, Maria Theresa's husband, Francis Stephen, former Duke of Lorraine, became Holy Roman emperor as Francis I. But she kept control over most state affairs.

Maria Theresa of Austria, portrait by Martin Van Mytens, Brooks Memorial Art Gallery, Memphis, Tenn.

Maria Theresa of Austria

The War of the Austrian Succession ended in 1748 with the Treaty of Aix-la-Chapelle. By this treaty, Maria Theresa lost almost all of the rich province of Silesia to Frederick II of Prussia (see **Frederick II** [of Prussia]). The powers of Europe recognized her rights to her other possessions. See **Succession wars**.

During the early 1750's, Maria Theresa strengthened her power at home and built a large army. In 1756, while she was planning to seek revenge for the loss of Silesia, Frederick II suddenly attacked again. The Seven Years' War followed, and Maria Theresa was forced to give up all claims to Silesia (see **Seven Years' War**). Her husband died in 1765, and her oldest son became Holy Roman emperor as Joseph II. In 1772, Maria Theresa joined with Russia and Prussia in a division of Poland and gained most of the region of Galicia. In 1775, she took the region of Bukovina from Turkey. Maria Theresa died in Vienna. Charles W. Ingrao

Mariana Islands, *MAIR ee AN uh,* are formed by the summits of 15 volcanic mountains in the Pacific. They are the southern part of a submerged mountain range that extends 1,565 miles (2,519 kilometers) from Guam almost to Japan (see **Pacific Islands** [map]). The Marianas are the northernmost islands of a larger island group called *Micronesia,* which means *small islands.* The Marianas have a total land area of 396 square miles (1,026 square kilometers) and a population of about 176,500. About 133,000 people live on Guam, and about 39,000 live on Saipan. The rest of the people live on other islands.

The Mariana Islands, except Guam, are a commonwealth of the United States. Island residents are U.S. citizens. Saipan is the capital of the commonwealth.

The 10 northern Marianas are rugged islands. Some of them have volcanoes that erupt periodically. Pagan, Agrihan, and Anatahan are the largest islands in this group. The limestone or reef rock terraces on volcanic slopes in the five southern Marianas show that they are older than the northern group. Guam is the largest of the southern islands. Other important islands are Rota, Saipan, and Tinian. Tourism is the major industry of Guam and Saipan. In addition, the U.S. military service employs many people on Guam.

The native islanders are called *Chamorros.* Their ancestors, who were among the earliest settlers of Micronesia, arrived from Asia thousands of years ago. The Chamorros have intermarried with Europeans, Filipinos, and other peoples. Today, they practice many Western customs.

The Portuguese explorer Ferdinand Magellan led the first European expedition to Guam and Rota. His party arrived in 1521. His sailors called the islands *Islas de los Ladrones,* or *Islands of Thieves,* because the islanders helped themselves to articles on the ships after furnishing supplies of food and water. The islands received their present name from Spanish Jesuits who arrived in 1668. Spain governed the islands from 1668 to 1898.

After the Spanish-American War (1898), the United States kept Guam as a naval base. Spain sold the rest of the islands to Germany. Japan occupied Guam in 1941, but American armed forces recaptured the island in July and August 1944 and built naval air bases on several of the islands. The Marianas, except for Guam, were governed by the United States as part of the United Nations Trust Territory of the Pacific Islands. In 1976, the United States agreed to form the Commonwealth of the Northern Mariana Islands, which would include all of the Marianas except Guam. This agreement went into effect in November 1986, making the people U.S. citizens. The government of the commonwealth controls its internal affairs, but the United States remains responsible for foreign affairs and defense. Robert C. Kiste

Mariana Trench. See Ocean (Depth).

Marie Antoinette, *AN twuh NEHT* (1755-1793), was the beautiful queen of France who died on the guillotine during the French Revolution. Her frivolity and plotting helped undermine the monarchy.

The young queen was lively and extravagant. The stiff formalities of court life bored her, so she amused herself with such pleasures as fancy balls, theatricals, and gambling. Marie lacked a good education and cared very little for serious affairs. She did not hesitate to urge the dismissal of the able ministers of France whose ef-

forts to reduce royal spending threatened her pleasures. Louis XVI gave her the château called the Petit Trianon, where the queen and her friends amused themselves (see **Versailles, Palace of**).

Marie became very unpopular and was blamed for the corruption of the French court. She lavished money on court favorites and paid no attention to France's financial crisis. Vicious stories were told about her. One of these stories illustrates the haughty attitude people associated with her name. According to the story, Marie once asked an official why the Parisians were angry. "Because they have no bread," was the reply. "Then let them eat cake," said the queen. The suffering people of Paris readily believed this false story.

Her early life. Marie was born in Vienna, Austria. She was the youngest and favorite daughter of Emperor Francis I and Maria Theresa, rulers of the Holy Roman Empire. Marie was brought up in the hope that she might one day be queen of France. She married the French *dauphin* (crown prince) in 1770. Four years later, he became King Louis XVI, and Marie became queen.

The revolution. Tragedy struck Marie twice in 1789. Her eldest son died, and the French Revolution started. Her weak-willed husband lost control of the nation. She tried to stiffen his will, but her stubborn opposition to the revolutionary changes only made people angrier.

The king, partly on Marie's advice, assembled troops around Versailles twice in 1789. Both times violence followed, and royal authority became weaker. The second time, early in October 1789, a hungry and desperate Parisian crowd marched to Versailles and forced the royal family to move to the Tuileries palace in Paris. From then on, Louis and Marie were virtual prisoners.

Marie Antoinette and Her Children in the Petit Trianon Park (detail) by Ulrich Wertmüller. Nationalmuseum, Stockholm

Marie Antoinette was a teen-ager when she became queen of France in 1774. She was executed less than 20 years later.

The rulers might have been able to rally the nation in support of a constitutional monarchy like that of England, had they followed the advice of moderate statesmen, such as the Comte de Mirabeau (see **Mirabeau, Comte de**). Instead, Marie Antoinette plotted for military aid from the rulers of Europe—especially from her brother, Leopold II of Austria. She refused to make any concessions at all to the revolutionists.

Downfall of the monarchy. Finally, Marie influenced Louis to flee from Paris on the night of June 20, 1791. The royal family set out in disguise by carriage for the eastern frontier of France. But an alert patriot recognized the king from his picture on French paper money. The king and queen were halted at Varennes and returned under guard to Paris. Their flight made the people distrust their rulers even more. But Louis promised to accept a new constitution that limited his powers.

Marie now worked to get aid from abroad, and, when war with Austria and Prussia came in 1792, she passed military secrets on to the enemy. The people suspected such treason. On Aug. 10, 1792, they threw the royal family into prison, ending the monarchy. Louis XVI died on the guillotine on Jan. 21, 1793. After bravely enduring imprisonment, Marie Antoinette, called Widow Capet by the revolutionists, was tried for treason. She died on the guillotine on Oct. 16, 1793. Isser Woloch

Marie de Médicis, *MEHD ih chee* or *may dee SEES* (1573-1642), was the second wife of King Henry IV and the mother of King Louis XIII of France. She was born in Florence, Italy, into the powerful Medici family. When Henry was assassinated in 1610, 8-year-old Louis inherited the throne. Marie became queen *regent* (temporary ruler). She ruled until Louis seized power in 1617.

Marie granted power to Leonora Galigaï, her childhood playmate, and to Leonora's husband, Concino Concini. The couple had a reputation for being corrupt and for misusing power. To stem rising opposition, Marie called a meeting of the legislative assembly, the Estates General, in 1614. But in 1617, Louis had Concini murdered and had Galigaï arrested. Galigaï was then tried and beheaded.

In 1624, Marie helped her friend Cardinal Richelieu get appointed to the royal council. Marie grew to resent Richelieu's power, and in 1630 she demanded that Louis dismiss him. Instead, the king banished Marie from the court. She fled to the Spanish Netherlands (now Belgium). Marie was a patron of the great Flemish painter Peter Paul Rubens. During the 1620's, Rubens depicted Marie's life in 21 grand pictures. Donald A. Bailey

Marie Louise (1791-1847) was the second wife of Napoleon Bonaparte and the daughter of Emperor Francis I of Austria. She married Napoleon in 1810 after his divorce from Josephine. Napoleon and Marie Louise had a son in 1811 who became known as Napoleon II.

Marie Louise was not permitted to go with Napoleon when he was exiled. She and her son lived at Schönbrunn, near Vienna, Austria. She received the Italian duchies of Parma, Piacenza, and Guastalla in 1816 and governed them until her death. Marie Louise was married twice after the death of Napoleon. She was born in Vienna. Donald Sutherland

See also Josephine; Napoleon I; Napoleon II.

Marigold is a hardy flowering plant commonly grown in gardens. Marigolds range from 6 inches to 3 feet (15 to 90 centimeters) in height. They generally have yellow, orange, or reddish-brown blossoms and feathery, fernlike leaves. Most have a strong odor. All cultivated marigolds are *annuals*—that is, they live for only one year.

There are about 50 species of marigolds. Six of these species are commonly cultivated: (1) African, also called Aztec or big, (2) French, (3) sweet-scented, (4) signet,

WORLD BOOK illustration by John F. Eggert

The African marigold is cultivated in many gardens.

(5) Irish lace, and (6) Muster-John-Henry. All marigolds are native to an area that extends from the Southwestern United States to Argentina. Spanish explorers brought marigolds to Europe in the early 1500's.

Marigolds are easy to grow. They can survive dry weather better than most other garden flowers can. Some marigolds produce an oil that repels *nematodes,* small worms that live as parasites on plant roots. Gardeners may grow such marigolds with other plants to protect those plants from nematodes. Margaret R. Bolick

Scientific classification. Marigolds belong to the composite family, Compositae.

See also Flower (picture: Garden annuals).

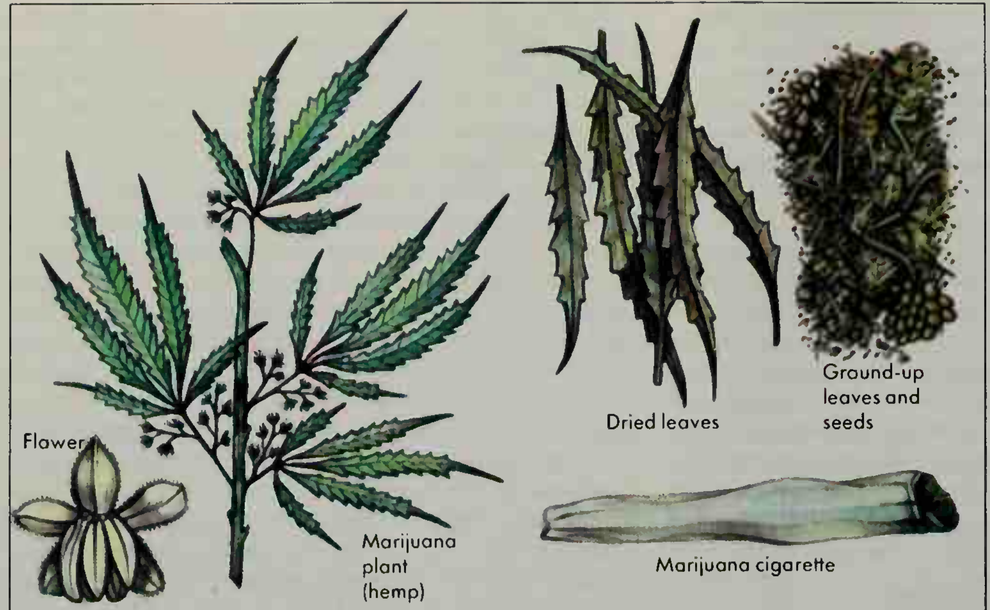
Marijuana, also spelled *marihuana,* is a drug made from the dried leaves and flowering tops of the hemp plant. Marijuana has many psychological and physical effects. People usually smoke marijuana in cigarettes or pipes, but it also can be mixed with food and beverages. Almost all nations, including the United States and Canada, have laws that prohibit the cultivation, distribution, possession, and use of marijuana.

Marijuana has many nicknames, including *grass, pot,* and *weed.* It is also called *cannabis,* a word that comes from *Cannabis sativa,* the scientific name for hemp.

Effects. Marijuana contains more than 400 chemicals. When smoked, it produces over 2,000 chemicals that enter the body through the lungs. These chemicals have a variety of immediate, short-term effects. In addition, the repeated use of marijuana has been linked to a number of long-term effects.

Short-term effects of marijuana include both psychological and physical reactions. These reactions usually last for three to five hours after a person has smoked marijuana. The psychological reaction, known as a *high,* consists of changes in the user's feelings and thoughts. Such changes are caused mainly by *THC,* a chemical in marijuana that impairs brain function.

The effects of a marijuana high vary from person to person and from one time to another in the same individual. In most cases, the high consists of a dreamy, relaxed state in which users seem more aware of their senses and feel that time is moving slowly. Sometimes, however, marijuana produces a feeling of panic and dread. The different reactions result partly from the concentration of THC in the marijuana. Other factors, such as the setting in which marijuana is used and the user's expectations, personality, and mood, also affect a person's reaction to the drug.



The short-term physical effects of marijuana include redness in the eyes and a rapid heartbeat. The drug also interferes with a person's judgment and coordination. Therefore, driving a motor vehicle while under the influence of marijuana is particularly dangerous.

Long-term effects of marijuana are not completely known. But studies have shown that some people who have used marijuana regularly for several months or longer develop serious problems. Use of marijuana harms memory and motivation. Some chronic users suffer bronchitis, coughing, and chest pains. Marijuana smoke also contains cancer-causing substances. Among males, marijuana use can reduce the production of sperm and of the male sex hormone *testosterone.* Among females, it can cause menstrual irregularity and reduced fertility. Extended use of marijuana also has a psychological effect on many people. These individuals lose interest in school, their job, and social activities.

Why people use marijuana. Most people who use marijuana begin to do so between the ages of 12 and 18. They try the drug because of curiosity. Some people believe marijuana improves their talents and capabilities. But scientists have found that marijuana impairs all abilities. A marijuana high gives some people a false sense of having important new ideas and achieving new understanding about life.

Many people who try marijuana use it only a few times or infrequently. However, others become regular users. Some regular users become dependent on the drug and have great difficulty in stopping its use.

History. Marijuana has been used as a medicine and an intoxicant for thousands of years in many parts of the world. In the United States, marijuana use has been prohibited by state and local laws since the early 1900's, and by federal law since 1937. In spite of these laws, use of the drug became widespread during the 1960's and 1970's, especially among young people. Between 1969 and 1978, the federal and many state governments reduced the criminal charge for possession of small amounts of marijuana from a felony to a misdemeanor.

WORLD BOOK illustration by Carol A. Brozman

Marijuana is an illegal drug that produces psychological and physical effects. It is made from the dried leaves and flowering tops of the hemp plant. Users commonly smoke marijuana in cigarettes or pipes.

Some states even substituted fines for jail sentences. Use of marijuana in the United States declined from the mid-1970's through the early 1990's. In the mid-1990's, however, marijuana use again began to rise.

Many people in the United States have urged investigation of the medical use of marijuana and the chemicals it contains. These people believe that marijuana may help certain serious conditions, including the nausea, vomiting, and loss of appetite that often accompany cancer and AIDS. In 1985, the U.S. Food and Drug Administration approved Marinol, a capsule containing THC, as a prescription drug.

Since 1996, voters in Arizona, California, Oregon, several other states, and the District of Columbia have passed laws allowing medical use of marijuana. But many doctors feel that the risks of smoking outweigh potential benefits. It is still illegal to prescribe the drug. In 1997, a panel organized by the National Institutes of Health decided that marijuana may have promise as a medicine and advised further study. Robert L. DuPont

Marimba, *muh RIHM buh,* is a percussion instrument that consists of a number of bars arranged on a frame like the keys of a piano. Most marimbas have bars of rosewood, but some have plastic bars. A musician strikes the bars with mallets that have heads of soft or hard rubber or of yarn. The sounds are amplified by metal tubes called *resonators,* one of which lies beneath each bar. Most marimbas have 49 to 52 bars with a range of from 4 to 4 $\frac{1}{2}$ octaves. The instrument produces a rich, mellow sound. Marimbalike instruments date from prehistoric times. Marimbas have become especially popular in Africa and in Latin America. Some Latin American marimbas are so long that four or five musicians can play at one time. John H. Beck

Marin, *MAIR uhn,* **John** (1870-1953), was one of the first American artists to paint in a modern style. He combined realistic images with elements of an abstract style called Cubism (see **Cubism**). Marin's paintings include bold, angular lines; vivid colors; patches of bare paper or canvas; and overlapping planes. Some of these planes cluster at the edge of the work to reinforce the frame. Many of Marin's water-color and oil paintings are seascapes and landscapes that express in abstract ways the powerful forces of change in nature. The active forms he used in his representation of objects give his work a sense of movement and energy.

Marin was born in Rutherford, New Jersey. He lived in Paris from 1905 to 1911 and traveled to the Netherlands, Belgium, and Italy. His work of this period shows

Karl Kummels, Shostal

The marimba is similar to a xylophone. Some Latin American marimbas, such as the one shown here, are so long that several musicians can play the instrument at one time.

Water color (1922); the Phillips Collection, Washington, D.C.

Peter A. Juley & Son

John Marin became famous for his vivid water-color paintings. Many of his works show dramatic scenes from nature. Marin's *Maine Islands,* shown here, reflects the blend of abstract and realistic elements that are typical of his style.

the influence of James A. M. Whistler, an American painter of the late 1800's. Marin first exhibited his paintings in Paris in 1908. His work was shown in the United States for the first time in 1909, at the gallery of Alfred Stieglitz in New York City. Stieglitz, a photographer and art promoter, was the chief spokesman for modern art in the United States. He became Marin's most active supporter.

Marin returned to the United States in 1911 and began to develop a distinctive personal style in response to both urban life and nature. Most of his paintings portray his immediate surroundings, such as New York City and the coast of Maine. A Maine seascape, the water color *Off Stonington* (1921), appears in the **Painting** article. He painted his impression of New York City in *Lower Manhattan* (1922). Marin traveled to other parts of the country to find new subjects for his paintings. *Storm Over Taos* (1930) reflects some of the beauty of New Mexico. Alison McNeil Kettering

Marine is a soldier who serves at sea and in special missions on land and in the air. Marines also serve in *amphibious operations*—seaborne operations that involve naval, air, and land forces. Marines receive specialized training for the tasks they are expected to perform. Nearly all of the major maritime nations maintain marine forces or some type of naval infantry.

In amphibious operations, marines attack from the sea to capture important enemy-held islands, beaches, or other locations on shore. By going ashore first, marines prepare the way for other soldiers to land and build bases or fight the enemy.

Some marine forces perform special or difficult missions, such as nighttime raids and actions against terrorists. Marines may also guard navy ships, navy yards, and government embassies. United States marines serve as guards at American embassies throughout the world. For more information on U.S. marines, see **Marine Corps, United States.**

Marines of other lands. The United States has the largest corps of marines in the world, with about 175,000 soldiers. Other nations that maintain large marine forces include Argentina, France, the Netherlands, the Philippines, Russia, South Korea, and the United Kingdom.

Globe Photos

British Royal Marines prepare to attack Argentine forces in a 1982 battle over the ownership of the Falkland Islands.

The British Royal Marines are part of the Royal Navy. The 8,000-member force operates landing craft and helicopters, and stages amphibious raids. Both the British and the Dutch marines have antiterrorist units.

History. The first marines were the *epibatae,* or "heavily armed sea-soldiers," of the Greek navies in the 500's B.C. Later, Roman warships carried *milites classiarii,* or "soldiers of the fleet." Both the Greeks and the Romans used their marines to fight at sea while sailors maneuvered the ships.

During the Middle Ages, European states did not maintain organized armies, navies, and marine forces. But it was common practice to put soldiers aboard ship whenever sea combat was expected. In the 1600's, nations began once again to organize permanent armed forces. Both England and the Netherlands recognized the need for regular troops aboard their warships. The British formed a corps of marines in 1664, and the Dutch did so in 1665. When the American Colonies revolted in 1775, the Continental Congress organized a force of marines modeled after the British Royal Marines.

In the 1900's, marine forces began to develop ways of getting soldiers ashore more quickly. Marines of several nations fought in World War I (1914-1918), World War II (1939-1945), the Korean War (1950-1953), and the Vietnam War (1957-1975). U.S. Marine units served in Lebanon from 1982 until 1984 as part of an international peacekeeping force there.

The British Royal Marines fought in the British-held Falkland Islands in 1982, after Argentine troops invaded and occupied the islands. In the 1980's, Soviet marines helped Afghanistan's government fight antigovernment rebels. John W. Gordon

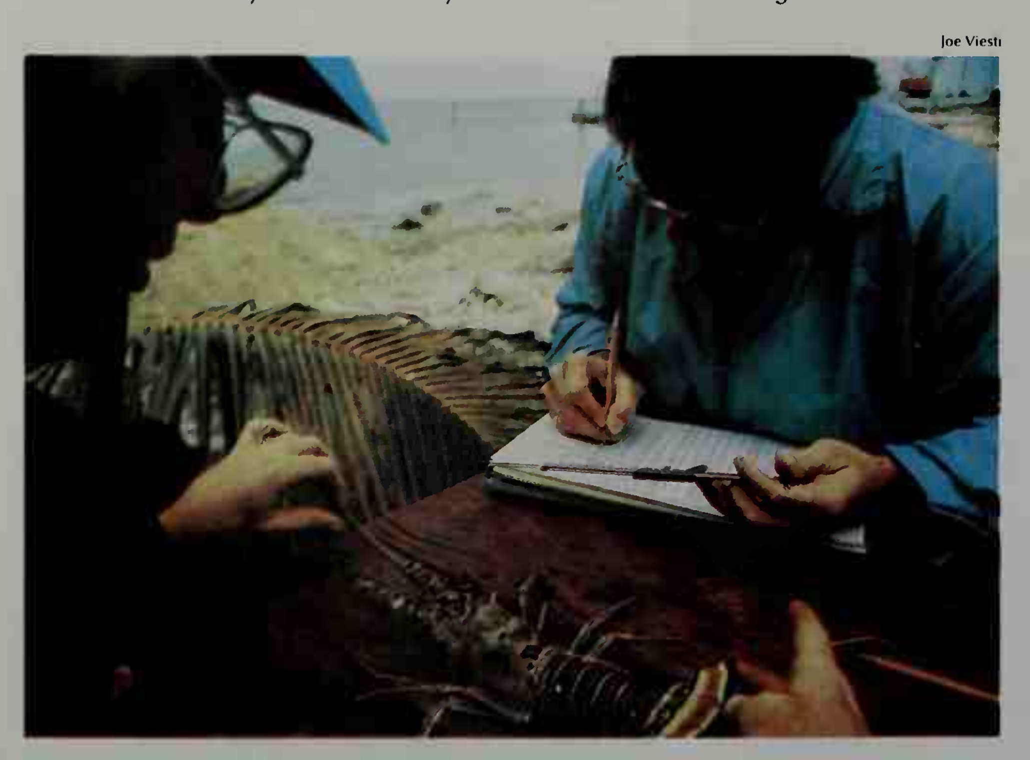
Marine Band, United States. See Marine Corps, United States (introduction).

Marine biology is the study of organisms that live in the sea. It deals with all forms of life in the oceans, from viruses so small they can be seen only with the most powerful electron microscopes to whales, the largest living animals.



Living things are found in all parts of the ocean, from the shores where waves splash onto the land to the deepest points of the ocean floor. Because people have always been able to visit the seashore at low tide and observe marine life, studies of marine biology began in shallow-water regions. Early marine biologists studied plants and animals from deep waters by using nets and other devices to collect samples. The development of scuba diving equipment has enabled biologists to observe marine organisms in their natural habitats, especially in the clear tropical waters along coral reefs. Scientists also can visit the deepest parts of the ocean in special underwater craft. Marine biologists who usually study life in deepwater regions are called *biological oceanographers.*

What marine biologists do. Marine biologists describe and classify marine organisms. They try to determine how these organisms develop, how they obtain food, how they reproduce, how they interact with other organisms, and why particular groups of organisms live in different regions of the ocean.

The work of marine biologists becomes increasingly important as people use more and more of the ocean's resources for food and recreation. Marine biologists seek to learn how extensively marine plants and animals can be harvested as food without destroying their natural populations. These scientists also investigate whether or not certain human activities, such as dumping waste products in the ocean, harm marine life.

Marine biologists try to discover what substances marine organisms produce that can be used to treat human diseases. They have found substances in sponges, soft corals, and other marine animals that appear to be effective in treating bacterial and viral infections. Other substances are being tested by drug companies as possible treatments for arthritis and various types of cancer, including leukemia.

Joe Viesti

Marine biologists study marine life in its environment. These scientists may travel long distances to an isolated area to study a particular marine animal. They collect data on the animal and on characteristics of its environment, such as water temperature and salt content.

Marine biologists use marine animals in experiments to increase our knowledge of human life processes. For example, much of our understanding about the early developmental states of organisms comes from the study of marine animals. In experiments with the eggs of sea urchins, marine biologists have determined how chemical substances influence development of *embryos* (developing young). Marine biologists have also used the squid's giant nerve fibers to discover how nerves work. The squid's nerve fibers are so large that scientists can place instruments inside different parts of the nerve to record mechanical, chemical, and electrical responses.

Many marine biologists do much of their work in special laboratories near seacoasts. Seawater is readily available there to maintain organisms for research. Among the most famous marine laboratories in the United States are the Marine Biological Laboratory of the Woods Hole Oceanographic Institution at Woods Hole, Massachusetts; Scripps Institution of Oceanography at La Jolla, California; and the University of Washington at Seattle's Friday Harbor Laboratory, located at Friday Harbor, Washington.

Biological oceanographers usually focus on the open ocean and deepwater regions of the oceans. In addition to studying the ocean's organisms, they investigate the physical and chemical nature of the ocean, including its temperature, salt content, and oxygen content. For example, they try to learn how sunlight, nutrients, and temperature in the sea affect the growth rate of the mass of tiny plantlike marine organisms known as *phytoplankton.* Phytoplankton forms the basis of the ocean *food web* (feeding interrelationships among organisms). Understanding how food webs function is important in determining how many fish can be harvested in different regions of the oceans.

Many biological oceanographers go to sea in special research vessels to study organisms in their natural environment. From these ships, they use water-sampling bottles, nets, dredges, and other collecting devices to take samples for further study. They also make use of *remotely operated vehicles* (ROV's). ROV's are small submarinelike "robots" that are controlled from research vessels on the ocean's surface. ROV's are equipped with video cameras that allow scientists to observe and record the behavior of organisms. Many ROV's also have mechanical arms to collect samples for study. Biological oceanographers visit the deepest regions of the ocean in deep-diving craft called *submersibles.*

Some of the most exciting discoveries in marine biology have come from studies in the deep ocean. In 1977, scientists used the submersible *Alvin* to study the sea bottom on the East Pacific Rise near the Galapagos Islands. To their surprise, they found large populations of bottom-dwelling organisms surrounding volcanic hot springs in the ocean crust, about 6,000 feet (2,000 meters) below the sea's surface. They did not expect to find such abundant life at that depth, where there was no phytoplankton to support the food web. Phytoplankton could not grow because light did not penetrate to that depth. Studies showed that bacteria living on chemicals in the hot springs provide the basis of the food web for this deepwater community. Some scientists now suggest that life on the earth may have started near such hot springs.

Biological oceanographers also are involved in studies of the ocean *ecosystem.* The ocean ecosystem consists of all living and nonliving things in the ocean and the relationships among them. In one such study, called the Joint Global Ocean Flux Study (JGOFS), oceanographers from throughout the world are investigating how activity of the ocean's food web might decrease the amount of carbon dioxide in the air. The amount of carbon dioxide in the atmosphere has slowly increased as people burn more coal, oil, and natural gas for energy. Many scientists believe that this increase has strengthened the *greenhouse effect,* the process by which the atmosphere traps heat from the sun. A stronger greenhouse effect could cause a potentially disastrous warming of the atmosphere.

Some carbon dioxide is used by the phytoplankton at the ocean's surface waters and then transferred through the food web to the ocean's depths. JGOFS research seeks to determine whether this activity will offset the increased amount of carbon dioxide in the air.

The Marine Corps War Memorial in Arlington, Virginia, *shown here,* honors all Marines who have died in action since 1775, the year the corps was founded. The memorial portrays the raising of the United States flag on the Pacific island of Iwo Jima during World War II.

Marine Corps, United States, is a branch of the U.S. armed forces that is especially trained and organized for military expeditions and amphibious operations. Marine assault forces, supported by air units and U.S. Navy warships, attack and seize enemy positions. As a "force in readiness," the Marines go to strategic areas as crisis reaction forces. Other missions may involve combat, peacekeeping, counterterrorism, civilian evacuations, or humanitarian assistance. The Marines serve and train for war in every climate, from the polar regions to the deserts and the tropics. They are often called *leathernecks* because in the early days they wore high leather collars around their necks.

A well-known military saying is "The Marines have landed, and the situation is well in hand." The Marines have been the first to fight in almost every major war of the United States. Since 1775, these "soldiers of the sea" have grown from two battalions of sharpshooters into an elite combat organization of Marine Expeditionary Forces composed of air wings, ground divisions, and *logistics* (supply) groups.

The U.S. Marine Corps is one of the two naval services within the Department of the Navy in the Department of Defense. The corps is a partner, but not a part, of the Navy. Navy amphibious ships transport Marine troops on missions. During the early 2000's, the Marine Corps had a strength of about 172,000 on active duty and 32,000 in the reserves.

The Marine Corps emblem

The motto of the corps, adopted in 1880, is *Semper Fidelis* (Always Faithful). The Marine emblem was adopted in 1868. "The Marines' Hymn," written in the 1800's, begins with the stirring words "From the halls of Montezuma to the shores of Tripoli." John Philip Sousa wrote the corps's march, "Semper Fidelis," while leading the Marine band. The band is called "The President's Own" because it plays for state affairs in the White House. The official colors of the corps are scarlet and gold.

The purpose of the Marine Corps

Every great maritime nation must be able to defend its interests on land and sea, and protect the lives and property of its citizens. The U.S. Marine Corps maintains Fleet Marine Forces of combined air and ground units to seize and defend advance bases, and for land operations that are carried out as part of a naval campaign. It develops the tactics, techniques, and equipment for amphibious landing operations. The corps provides detachments for service aboard warships and for the protection of naval bases and stations. It guards U.S. embassies, legations, and consulates in other countries. The corps also guards the White House, the presidential retreat at Camp David, and the U.S. Naval Academy. Marine Fleet Antiterrorist Security Teams and a Chemical Biological Incident Response Force stand ready to go to any part of the world. The Marine Corps also performs other duties as directed by the president.

Life in the Marine Corps

Training a Marine. Marine recruits receive basic training in *boot camp.* Recruits are called *boots* because in early days they wore leather leggings that looked like boots. Marine recruits receive about 12 weeks of basic training. They undergo physical conditioning and learn to shoot, drill, obey orders, and follow the traditions of

the corps. Men train at one of two recruit depots—in Parris Island, South Carolina, or in San Diego. Women train at Parris Island.

Training an officer. Marine Corps officers come from four main sources: (1) the U.S. Naval Academy, (2) the Naval Reserve Officers Training Corps, (3) civilian universities, and (4) the enlisted ranks of the corps. Each officer receives six months of initial training at the Marine Corps Basic School in Quantico, Virginia. Much of this training covers field tactics, leadership, marksmanship, infantry weapons and supporting arms, drill, military law, and physical fitness.

A typical day. Because of the wide variety of Marine duties, there is no completely typical day. A normal day for *garrisoned* Marines—that is, Marines at a base—involves training, maintenance, and administrative duties. The normal garrison routine starts with early morning exercises called *physical training.* After showering and changing into the appropriate uniform, the Marines begin their daily work. At noon, they break for lunch. In the late afternoon, when the work is finished, the Marines assemble into formation and receive a briefing on the next day's missions. They are then *secured* (released) for *liberty* (free time) and have the evening to themselves.

Careers in the Marine Corps. Young men and women from the ages of 17 to 28 may enlist in the corps for three, four, or six years. Men may serve in a wide variety of job fields. Women can serve in all military job fields except ground combat specialties, such as armor, artillery, and infantry.

Marines who reenlist may, if qualified, rise to jobs as senior noncommissioned officers. The most capable Marines can win appointments to the U.S. Naval Academy, receive direct commissions as officers, or be chosen as warrant officers. Marines may retire with pay after 20 years' service.

Weapons and equipment

Marine ground weapons. The M16A2 rifle is the basic infantry weapon of the corps. The Marines also use grenades, pistols, and machine guns.

Artillery provides support for Marine infantry. Marine artillery includes mortars, guns, and howitzers. Armored units have tanks with heavy guns. Antiaircraft weapons include Hawk guided missiles and shoulder-fired Redeye and Stinger missiles. Special Marine teams ashore use radio to direct gunfire from warships.

Marine aviation provides close air support for Fleet Marine Forces and other troops. It reinforces naval aviation. Marine aviation attacks enemy forces so close to Marine land operations that detailed coordination between air and ground units is required. The Marines have aviators with ground units at the front lines to control and direct air support. They fly the same kinds of aircraft as the Navy (see Navy, United States [Naval aviation]). The Marines also fly the Harrier, a type of V/STOL (Vertical/Short Take-Off and Landing) aircraft. In addition, the Marines operate assault helicopters to land men from naval helicopter carriers.

Organization of the Marine Corps

Headquarters of the Marine Corps is in Washington, D.C. A commandant, appointed by the U.S. president, heads the corps. The commandant usually serves four years and has the rank of general. The commandant serves on the Joint Chiefs of Staff and reports directly to the secretary of the Navy. The commandant's principal assistants include the assistant commandant and chief of staff, the deputy and assistant chiefs of staff, and the directors of headquarters departments and divisions.

Operating forces account for almost two-thirds of the entire Marine Corps. They consist of (1) the Fleet Marine Forces, (2) Marines aboard ships, and (3) security forces. The Fleet Marine Forces make up the corps's combat strength and form parts of the Atlantic and Pacific fleets. They consist of three Marine divisions, three Marine aircraft wings, and various support units. The combat units operate as air-ground teams. One division and wing team is based on the East Coast of the United States, another is on the West Coast, and the third is in the Far East and Hawaii. The teams remain combat ready at all times. A fourth division and wing team, composed of elements of the Marine Corps Reserve, stands ready to reinforce the active forces when needed.

Marines serve on many warships. They provide internal security aboard the vessels. They also take part in amphibious warfare and land operations in connection with naval campaigns. Marine airplane and helicopter squadrons may fly from carriers.

Security forces include Marines who guard American embassies and other important government installations and naval bases around the world.

The supporting establishment provides administrative, supply, training, and recruiting support for the operating forces. The Marine schools combine the corps's education and military development activities. The corps's two recruit depots handle basic training. The Marine logistics bases provide support.

Reserves. The Marine Corps Reserve consists of (1) the Ready Reserve, (2) the Standby Reserve, and (3) the Retired Reserve. Many members of the Ready Reserve enlist for six years to serve in selected reserve units. They train one weekend a month and serve two weeks of active duty each year. Other members of the Ready Reserve may volunteer to train with these reserve units, or they may take other types of training.

The Standby Reserve is for Marines who complete their military obligation and remain in the reserves. They do not undergo the scheduled training required of the Ready Reserve. The Retired Reserve is made up of reserve Marines who have been active in training for 20 years or more. There are about 110,000 Marines in the reserves, and all of them may be called to active duty, depending on the situation.

History

The early Marine Corps. The Continental Congress established a Marine Corps on Nov. 10, 1775, to fight in the Revolutionary War in America. Marines also served with the Continental Army in the battles of Trenton, Assunpink, Morristown, and Brandywine. After the war, no corps as such existed. The U.S. Congress re-created the Marine Corps as a military service in 1798. Marines fought many naval battles with France from 1798 to 1801.

The 1800's. In 1805, the Marines led the storming of a Barbary States' stronghold at Derna, Tripoli (now part of Libya), helping end raids on ships in the Mediterranean Sea. The War of 1812 saw the Marines in all the major

Combat uniform **Aviator uniform** **Women's service uniform** **Blue dress uniform**

American naval victories. Captain John Gamble showed such ability that he was given command of a captured British warship. He became the only Marine officer ever to command a naval ship. The Marines helped Andrew Jackson's army administer the worst defeat of the war to the British in the defense of New Orleans in 1815.

During the Mexican War, from 1846 to 1848, the Marines made many landings on both coasts of Mexico. The Marines entered the city gates of Mexico City. They raised the American flag over the National Palace, which later became known as "the halls of Montezuma."

When the American abolitionist John Brown and his followers captured the army arsenal at Harpers Ferry, Virginia, in 1859, Marines from Washington were the only troops available. They helped capture Brown and occupied the arsenal. In the American Civil War (1861-1865), the Marines fought in many land and naval battles.

During the late 1800's and early 1900's, the Marines landed 17 times in China to protect U.S. interests. They defended the besieged legations in Beijing during the Boxer Rebellion in 1900, and also fought at Tianjin in the Beijing relief force.

During the Spanish-American War, Marines were the first American troops to land in Cuba. A battalion seized Guantánamo Bay in 1898. Marines were also the first American forces to land in the Philippines. They occupied Guam and took part in the seizure of Puerto Rico. A Marine brigade served with the Army during the Philippine insurrection from 1899 to 1903.

The 1900's. The Marines landed in Panama six times from 1885 to 1903 to protect American lives and property and to keep the Isthmus of Panama open. They also fought in two campaigns to stabilize Nicaragua, in 1912 and again from 1926 to 1933. Marine brigades occupied Haiti from 1915 to 1934 and the Dominican Republic from 1916 to 1924 to quiet political unrest there.

During World War I, the Marines arrived in France in June 1917 with the first troops of the American Expeditionary Forces. They dismayed the Germans with long-range rifle fire and fierce assaults at Soissons, St.-Mihiel, Blanc Mont Ridge, and the Meuse-Argonne.

In August 1942, the Marines invaded Guadalcanal in the Solomon Islands and launched the first American offensive of World War II. Marines under Lieutenant General Holland M. Smith led the amphibious landings of an island-hopping drive westward through the Central Pacific. The conquest of the Pacific island of Iwo Jima during February and March of 1945 was the largest all-Marine battle in history. The strength of the corps reached nearly 500,000 during World War II.

In August 1950, the Marines entered the Korean War, arriving in Korea to help rescue the crumbling Pusan perimeter. They later made an amphibious landing at Inchon. After Chinese Communist troops entered the Ko-

Important dates in Marine Corps history

1775 The Continental Congress authorized the formation of two battalions of Marines.

1776 The Marines made their first landing, on the Bahama Islands during the Revolutionary War in America.

1798 Congress re-created the Marine Corps as a separate military service.

1805 The Marines stormed one of the Barbary States' strongholds, at Derna, on the shores of Tripoli.

1834 Congress placed the Marine Corps directly under the secretary of the Navy.

1847 The Marines occupied "the halls of Montezuma" in Mexico City during the Mexican War.

1913 The Marine Corps established its aviation section.

1918 The Marines fought one of their greatest battles at Belleau Wood in France during World War I.

1942 The Marines invaded Guadalcanal Island in the first United States offensive of World War II.

1945 The Marines seized Iwo Jima Island in the western Pacific in the largest all-Marine battle.

1950 The Marines stormed ashore at Inchon, Korea, in the first major landing of the Korean War.

1965-1971 The Third Amphibious Force, the largest field command in Marine Corps history, served in Vietnam.

1991 The Marines liberated Kuwait City during the Persian Gulf War.

rean War, the Marines smashed seven enemy divisions in their winter march south from the Changjin (Chosin) Reservoir.

During the Suez crisis in 1956, a Marine battalion aided the evacuation of U.S. citizens from the trouble zone. In 1958, a Marine regiment helped prevent the overthrow of the Lebanese government. Marine units ended fighting in the Dominican Republic in 1965. From 1965 to 1973, about 450,000 Marines served in the Vietnam War.

Recent Marine operations. From 1982 to 1984, several Marine units formed part of an international force attempting to preserve order in Lebanon, which was torn by civil war between Lebanese Christians and Lebanese Muslims and their allies in the Palestine Liberation Organization (PLO). In 1983, the Marines helped defeat rebel forces that had seized the government of Grenada. About 94,000 Marines served in the Persian Gulf War (1991). During the 1990's, the Marines participated in NATO (North Atlantic Treaty Organization) operations in Bosnia-Herzegovina and Serbia.

Marines also serve in what are called *military operations other than war,* abbreviated MOOTW. These operations include humanitarian missions, such as one in 1992 to facilitate the distribution of food in famine-stricken Somalia against the opposition of military warlords. MOOTW also include the evacuation of civilians threatened by civil strife in their countries, such as operations in Rwanda in 1994 and Sierra Leone in 1997.

Mariner space probe. See Venus (planet); Mars.

Marino, Dan (1961-), was one of the greatest quarterbacks in football history. He was especially known for his accurate passing. Marino was also noted for his ability to make quick decisions and deliver the ball quickly to receivers, as well as his skill at "reading" defenses for weaknesses. Marino set career records in the National Football League (NFL) for passing yards (61,361), touchdowns (420), passing attempts (8,358), and completions (4,967). In the 1984-1985 season, he set a single-season NFL record with 48 touchdown passes and 5,084 yards passing.

Daniel Constantine Marino, Jr., was born on Sept. 15, 1961, in Pittsburgh, Pennsylvania. He played at the University of Pittsburgh, graduating in 1983. Marino was drafted by the Miami Dolphins of the NFL in 1983, the 27th player and 6th quarterback taken. He became the Dolphins' starting quarterback in the sixth game of his rookie season and went on to set a record for passing accuracy by a first-year player. He was awarded the Jim Thorpe Trophy as the NFL's Most Valuable Player for the 1984-1985 season. Marino retired in 2000 after playing 17 seasons in the NFL. Bob Carroll

In Vietnam, *below,* the Marines defended their base at Khe Sanh in 1968 during a 77-day siege by Communist forces.

The Inchon landing, *above,* by Marine forces in 1950 turned the tide of the Korean War in favor of the Allies.

Marino, Eugene Antonio (1934-2000), became the first African American to be named an archbishop of the Roman Catholic Church. Appointed by Pope John Paul II, Marino served as archbishop of Atlanta from 1988 to 1990.

Marino was born on March 29, 1934, in Biloxi, Mississippi. He was ordained a priest in 1962. In 1971, Marino became the first black vicar general of a major Roman Catholic religious order, St. Joseph's Society of the Sacred Heart, also called the Josephites. He held this position until 1974, when he was appointed auxiliary bishop of Washington, D.C. Marino was auxiliary bishop until his appointment as archbishop of Atlanta. He was also the first black secretary of the National Conference of Catholic Bishops. Kenneth Guentert

Marion, Francis (1732?-1795), was an American military leader from South Carolina whose shrewd, daring raids in the Revolutionary War in America won him the nickname of The Swamp Fox. He and his soldiers repeatedly darted out of the marshes to attack the British and Americans who supported them and then vanished before their victims could strike back.

Marion was born in Berkeley County, South Carolina. He spent his youth on his parents' farm near Georgetown, South Carolina. He had his first experience in war as a lieutenant of colonial militia in 1761, when he led an attack against the Cherokee Indians.

In 1775, at the start of the Revolutionary War, Marion became captain of a militia company. He helped defend Charleston, South Carolina, against a British attack in 1776. The British captured Charleston in May 1780. But Marion had left the city before it surrendered.

Few American troops remained in South Carolina after the British won the Battle of Camden in August 1780. Marion managed to gather only a band of fighters, which was too small to fight the British in open battle. So Marion used the band as guerrillas, favoring ambushes and sudden raids. Ammunition was scarce. In many battles, each soldier often carried no more than three rounds.

Marion's band hid on Snow Island in the Pee Dee River, in northeastern South Carolina. From there, he and his soldiers made lightning-quick raids on British communications and supply depots and rescued captured Americans. British Lieutenant Colonel Banastre Tarleton spent much time chasing Marion through the swamps but could not catch him. For this reason, Tarle-

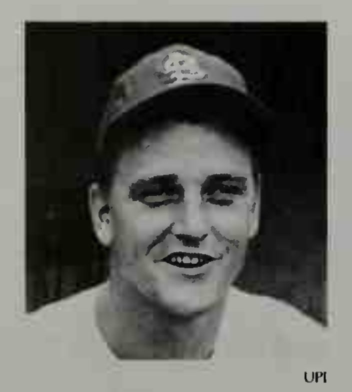
ton gave Marion his nickname. After the war, Marion served several terms in the South Carolina Senate. He died on his plantation at Pond Bluff. James Kirby Martin

Marionette. See **Puppet** (Marionettes).

Mariposa lily, *MAR uh POH suh* or *MAR uh POH zuh,* is a group of about 60 species of spring-blooming flowers of the lily family. The beautiful flowers are sometimes called *fairy lantern, globe tulip, sego lily,* or *butterfly lily.* The petals of the blossoms resemble a butterfly's wings. *Mariposa* is the Spanish word for *butterfly.*

WORLD BOOK illustration by Robert Hynes

Mariposa lilies have lovely, tulip-shaped flowers.



Mariposa lilies have narrow leaves shaped like blades of grass. The cup-shaped flowers grow singly or in small clusters and look like tulips. Colors range from white to purple to deep yellow or orange. The lilies grow well in sandy, porous soil, but need much water. They grow from underground bulbs. Bulbs should be dried out in summer for fall planting. In their native region—the western United States—the lilies make excellent flowers for woodland or rock gardens. Anton A. Reznicek

Scientific classification. Mariposa lilies make up the genus *Calochortus* in the family Liliaceae.

See also **Sego lily.**

Maris, *MAR ihs,* **Roger** (1934-1985), held the major league record for home runs in one season from 1961 to 1998. Maris had set the record when he hit 61 homers in 1961. His team, the New York Yankees, played a 162-game schedule that year. In 1927, Babe Ruth, also a Yankee, hit 60 homers in a 154-game schedule. Both totals were considered records until 1991, when Maris's 61 homers were recognized as the sole record. The record stood until 1998, when Mark McGwire of the St. Louis Cardinals hit 70 home runs.

Maris, an outfielder, batted left-handed and threw right-handed. He started his major league career with the Cleveland Indians in 1957 and was traded to the Kansas City Athletics in 1958. In 1960, his first year with the Yankees, he hit 39 home runs. Maris was voted the American League's most valuable player in 1960 and 1961. After the 1966 season, he was traded to the St. Louis Cardinals. He retired from baseball after the 1968 season.

UPI

Roger Maris

Roger Eugene Maras was born on Sept. 10, 1934, in Hibbing, Minnesota, and grew up in Fargo, North Dakota. He changed his last name to Maris in 1955. He died on Dec. 14, 1985. Dave Nightingale

Marisol, *MAR uh SAHL* (1930-), is an American sculptor known for her witty, life-sized wooden figures. She constructs her figures with crudely carved wooden blocks, on which she draws or paints realistic facial features and other details, such as clothing. Marisol often attaches everyday objects as well as plaster casts of her own face, hands, or feet to her sculptures.

Although she occasionally makes sculptures of recognizable personalities, most of Marisol's works portray fictional, ordinary people. Many of Marisol's sculptures consist of groupings of several physically independent figures. An example is *The Family,* which appears in the **Sculpture** article. Marisol's work has often been associated with the pop art movement. But unlike pop artists, she rarely depicts commercial objects or designs.

Marisol Escobar was born in Paris of Venezuelan parents on May 22, 1930. She immigrated to the United States in 1950. Deborah Leveton

Maritain, *ma ree TAN,* **Jacques,** *zhahk* (1882-1973), a French philosopher, was one of the most influential Roman Catholic scholars of the 1900's. He was a leader of *neo-Thomism,* a revival of the philosophical system developed by the medieval theologian Saint Thomas Aquinas. The system attempted to reconcile faith and reason.

Much of Maritain's work dealt with the theory of knowledge. In *The Degree of Knowledge* (1932), he analyzed the structure of thought, identifying three types of knowledge. They were, in ascending order: (1) scientific knowledge of empirical reality, (2) metaphysical knowledge of the principles of "being as such," and (3) suprarational knowledge of God through divine revelation. By suprarational knowledge, Maritain meant knowledge beyond the comprehension of human reason.

Maritain was born on Nov. 18, 1882, in Paris. He converted from Protestantism to Roman Catholicism in 1906. He was the French ambassador to the Vatican from 1945 to 1948. Maritain's other major books include *Art and Poetry* (1935), *Integral Humanism* (1936), *The Range of Reason* (1948), and *Man and the State* (1951). He died on April 28, 1973. David E. Klemm

Maritime Administration, *MAR ih tym,* is an agency of the United States Department of Transportation. The agency promotes a strong and efficient U.S. merchant marine. It works to meet the nation's waterborne shipping demands in times of peace and to support the armed forces during a national emergency. It also conducts promotional and marketing programs to increase domestic shipping, port development, and the use of U.S. vessels in foreign trade.

The agency trains young men and women to become deck and engineering officers at the U.S. Merchant Marine Academy at Kings Point, New York (see **Merchant marine**). In addition, the agency provides support to six state-operated maritime academies.

The Maritime Administration negotiates maritime

agreements with other nations and participates in international maritime forums. It also maintains a National Defense Reserve Fleet for use in national emergencies. The Maritime Administration was established in 1950.

Critically reviewed by the Maritime Administration

Maritime Commission, Federal. See Federal Maritime Commission.

Maritime, *MAIR ih tym,* **law** regulates commerce and navigation on the high seas or other navigable waters, including inland lakes and rivers. It involves all vessels, from huge passenger liners to small pleasure boats, and covers such matters as contracts, insurance, property damage, and personal injuries. Maritime law is sometimes referred to as *admiralty law,* because at one time it was administered under the jurisdiction of admirals.

Although a general maritime law has developed internationally, it operates in any nation according to the laws and usages of that country. Each nation bases its own maritime law on the general law. There is no international court to enforce maritime decisions. But all nations that have vessels on the sea set up national courts. These courts consider maritime cases in much the same way that civil courts hear other kinds of complaints. Federal district courts administer maritime law in the United States. Admiralty courts handle maritime cases in the United Kingdom. George P. Smith II

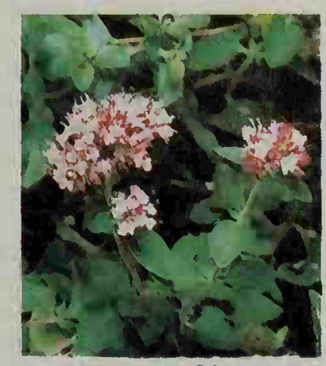
Maritime Provinces. See Atlantic Provinces.



Marius, *MAR ee uhs,* **Gaius,** *GAY uhs* (157-86 B.C.), was a Roman general and statesman. He was not of noble ancestry, but he worked his way into political leadership. He served seven times as one of the two *consuls* (chief government officials) of Rome, between 107 and 86 B.C. He opposed Rome's aristocratic *oligarchy* (rule by a few).

As a general, Marius reorganized Rome's infantry legions, improved training methods, and opened military service to men of the lowest social classes. A strong professional army developed. The troops, if treated well, often became more loyal to their generals than to the state, so successful military command became a means to political power. Marius was born near Arpinum, in central Italy. He won his greatest military victories against the Numidians in North Africa, and the Cimbri and Teutone tribes in northern Italy. Arther Ferrill

Marivaux, *ma ree VOH,* **Pierre** (1688-1763), was a French playwright and novelist. His novels and some of his plays deal with the rising middle class, which was slowly replacing the nobility as the ruling social force in France. Many of his plays offer subtle analysis of the psychology of love.

Marivaux is best known for his comedies. His originality lies in his basing them on the birth of love and its struggle against the individual's pride. His heroines are elegant, intellectual, and cunning, and their speech is delicate and refined. His comedies include *The Double Inconstancy* (1723), *The Game of Love and Chance* (1730), and *The False Confessions* (1737). His two unfinished novels, *The Life of Marianne* (1731-1741) and *The Successful Peasant* (1735-1736), were among the first French novels to give a realistic picture of the middle class. Marivaux was born Pierre Carlet de Chamblain de Marivaux in Paris. Carol L. Sherman

Marjoram, *MAHR juh ruhm,* is the name of a group of fragrant plants that belong to the mint family. Marjoram is a source of *oregano,* a seasoning used for many Italian foods. Most oregano sold in the United States is made from the dried leaves of wild marjoram. Wild marjoram is native to dry areas from western Europe to central Asia. In eastern North America, it has escaped from cultivation and grows as a weed. This plant grows from 2 to 4 feet (61 to 121 centimeters) tall. It has purplish stems and leaves with white or purplish flowers.

© Giuseppe Mazza
Marjoram

Another type of marjoram, sweet marjoram, is native to northern Africa and southwestern Asia. It grows to about 2 feet tall and has white, purplish, or pink flowers. Sweet marjoram is a popular cooking herb, especially for French foods. It also serves as a scent for soap, perfume, and other toiletries. Donna M. Eggers Ware

Scientific classification. Marjoram is in the mint family, Lamiaceae or Labiatae. The scientific name for wild marjoram is *Origanum vulgare.* Sweet marjoram is *O. majorana.*

See also Oregano.

Mark was a monetary unit of Germany. In 1924, it became known as the *reichsmark.* It later became the *Deutsche mark.* In 2002, it was replaced by the euro.

Mark, Saint, sometimes called John Mark, was an early Christian who accompanied Saint Paul on his first missionary journey. The Acts of the Apostles reports that Mark caused a dispute between Paul and Barnabas, another of Paul's companions. Mark left them to return to Jerusalem, his home. Mark and Barnabas traveled together as missionaries to Crete after the disagreement. Mark may have been related to Barnabas. According to tradition, Mark was the author of the second Gospel. Mark is also said to have been Saint Peter's "interpreter" in Rome and to have founded the church in Alexandria, Egypt. He is also said to have died a martyr's death. His feast day is April 25. Richard A. Edwards

Mark Antony. See Antony, Mark.

Market economy. See Capitalism.

Market research is the process of gathering and analyzing information to help business firms and other organizations make marketing decisions. Business executives use market research to help them identify *markets* (potential customers) for their products and decide what marketing methods to use. Government officials use such research to develop regulations regarding advertising, other sales practices, and product safety.

Market research services are provided by several kinds of companies, including advertising agencies, management consultants, and specialized market research organizations. In addition, many large business companies have their own market research department.

Market researchers handle a wide range of tasks. They estimate the demand for new products and services, describe the characteristics of probable customers, and measure potential sales. They determine how prices

influence demand, and they test the effectiveness of current and proposed advertising. Market researchers also assess a company's sales personnel and analyze the public "image" of a company and its products.

A market research study begins with a statement of the problem that the client wants to solve. This statement leads to a detailed definition of the information to be gathered. There are two types of market research information, *secondary data* and *primary data.*

Secondary data are statistics and other information that are already available from such sources as government agencies and universities. To save time and money, market researchers use secondary sources as much as they can. Primary data are data that must be obtained through research. The chief techniques for gathering such data include mail questionnaires, interviews, retail store shelf audits, use of electronic scanners at retail checkout counters, and direct observation in stores. The researchers design and test research materials, such as questionnaires or guides for interviewers. Finally, they collect the data, analyze the information, and report the results of their study. The computer is an important tool in analyzing market research data.

Market research can reduce the risk involved in many business decisions, but some risk always remains. Expenditures for market research must be carefully controlled so that the costs do not exceed the probable benefits from reduced risk. Frederick E. Webster, Jr.

McQuarrie, Edward F. *The Market Research Toolbox: A Concise Guide for Beginners.* Sage, 1996.
Zikmund, William G. *Exploring Marketing Research.* 7th ed. Dryden, 1999.

Marketing is the process by which sellers and buyers find each other and by which goods and services move from producers to consumers. Marketing has produced the vast array of products available to consumers in most countries of the world. Marketing activities are so important that, in some industries, they may account for half the cost of a product or service.

Businesses typically engage in five main marketing activities: (1) market research, (2) product development, (3) distribution, (4) pricing, and (5) promotion.

Market research is the study of the probable users of a product. This pool of potential customers is called a *market.* Many firms use surveys to determine what customers say they need or want. Other firms carefully observe what customers actually buy to learn about their habits. There are many other sources of valuable market information. For example, government statistics about population and income can indicate the size of a market and its purchasing power.

Since the 1990's, businesses have used the Internet to sell nearly every type of product. Marketing over the Internet generates more detailed information about customer interests and buying behavior than ever before. Some people believe that this information is unreliable or that it puts customers' privacy at risk. Others argue it helps companies to better meet consumers' needs.

Product development includes the design, creation, and modification of products and services, usually based on market research. Firms continually introduce new products, modify existing ones, and drop unprofitable products to meet the demands of the public.

Distribution is the movement of goods and services from the producer to the consumer. Manufacturers create systems, called *channels of distribution,* to keep goods moving. Participants in a channel of distribution include *wholesalers,* who sell large quantities of goods to *retailers.* Retailers, in turn, sell the goods in smaller quantities to consumers. Marketing channels may involve other companies that provide such services as financing, transportation, and storage.

The Internet has created electronic alternatives to some of the traditional physical channels of distribution. For example, many Internet marketers sell directly to the public, lessening the need for local retailing.

Pricing. If an item's price is too high, it will not sell. If an item's price is too low, the producers will not earn a profit. The pricing function must balance these extremes. When setting the price of an item, many manufacturers start with its *unit production cost,* the expense of making one unit of the item. They then add a percentage of this cost, called a *markup,* to provide a profit for themselves. Every other firm in the channel of distribution also adds a markup to cover expenses and to provide a profit. Therefore, the final selling price is the unit production cost plus the total of all the markups.

Other manufacturers try to determine what an item's price should be through market research. Then, manufacturing and other costs are managed to ensure that the company will make a profit. Certain Internet marketplaces allow customers to state the price they want to pay and then let sellers choose whether to compete for that business.

Promotion includes advertising, coupons, direct mailings, in-store displays, Web pages, telemarketing calls, and personal sales efforts. Companies engage in a wide range of promotional activities designed to inform customers about products and services and to persuade them to buy. Jehoshua Eliashberg and Gary L. Lilien

Markham, *MAHR kuhm,* **Edwin** (1852-1940), was an American poet. He wrote many volumes of poetry, but he is best remembered for two individual poems. They are "The Man with the Hoe" (1899) and "Lincoln, the Man of the People" (1901).

"The Man with the Hoe" is a powerful work of social protest based on a painting by Jean François Millet of France. The poem sympathetically portrays a poor farmer who has become brutalized by years of overwork. It refers to the farmer as "... a brother to the ox" and attacks those who have taken advantage of his labor. In "Lincoln, the Man of the People," Markham commem-

orated the American President Abraham Lincoln.

Markham was born in Oregon City, Oregon. His real name was Charles Edward Anson Markham. He worked as a schoolteacher and school principal before the popularity of "The Man with the Hoe" enabled him to devote himself to writing. William Harmon

Markova, *mahr KOH vuh,* **Alicia** (1910-), is considered the first great English ballerina. At 14, she joined Sergei Diaghilev's Ballets Russes and became a soloist. After the company disbanded in 1929, she danced with Ballet Rambert (now the Rambert Dance Company) and with the Sadler's Wells Ballet (now the Royal Ballet). With these companies, she performed all the principal ballerina roles in the first English productions of the classics. In 1935, she formed the Markova-Dolin Ballet with English dancer Anton Dolin. Her greatest role was the title character in *Giselle.* Markova described her experiences in the role in *Giselle and I* (1960). She also wrote a memoir, *Markova Remembers* (1986).

Markova was born in London. Her real name is Lillian Alicia Marks. She retired as a dancer in 1963 and then served as director of the Metropolitan Opera Ballet in New York City until 1969. She remained active as a coach, teacher, and lecturer. Queen Elizabeth II made Markova a Dame Commander of the Order of the British Empire in 1963, and she became known as Dame Alicia Markova. Dorothy Lourdou

Marlborough, *MAHRL buh ruh* or *MAWL buh ruh,* **Duke of** (1650-1722), was one of England's greatest generals. He won a series of brilliant victories at Blenheim, Ramillies, Oudenaarde, and Malplaquet in his campaigns in the War of the Spanish Succession (see **Blenheim, Battle of; Succession wars** [The War of the Spanish Succession]).

Marlborough's character and motives have been criticized, but his military genius has never been questioned. He was also a successful diplomat.

Marlborough deserted King James II to support William of Orange when English leaders invited William to invade England in 1688 (see **James** [II]; **William III**). William made him Earl of Marlborough and gave him commands in the army. Marlborough's position became stronger when William died and Princess Anne came to the throne as Queen Anne (see **Anne**). Marlborough's wife, Sarah Jennings, was the queen's closest friend. Anne made Marlborough commander of all the armed forces at home and in Europe.

In the War of the Spanish Succession, Marlborough, then a duke, won a series of victories. At the peak of his success, Marlborough lost his influence at home. His political enemies had turned the queen against him and his wife. He was removed from his command, and he retired from public life. His downfall was not due to lack of ability. It was the fault of his wife, who was domineering and ill tempered. England generously rewarded him for his services. He received an estate in Oxfordshire, and Blenheim Palace was built for him there in 1705.

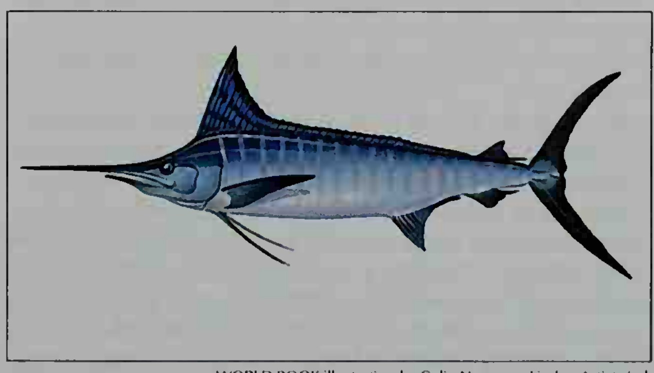
Marlborough was born in Devonshire. His given name was John Churchill. He was an ancestor of Sir Winston Churchill, who wrote a biography of him. Marlborough served in the war against the Netherlands, under the French Marshal Turenne, the greatest military leader of that day. Philip Dwight Jones

Marley, Bob (1945-1981), was a Jamaican musician and composer who popularized a style of music called *reggae.* Reggae songs feature lyrics about social problems and music dominated by the pulsing rhythms of electric guitars and drums. See **Reggae.**

Robert Nesta Marley was born in St. Ann's, Jamaica. He made his first record at the age of 17. In 1963, Marley formed a group called the Wailers that included Bunny Livingston and Peter Tosh. Marley was the group's lead guitarist and eventually its lead vocalist. In 1968, Marley converted to the Rastafarian faith, many of whose members at that time worshiped Emperor Haile Selassie of Ethiopia. His music strongly reflected his beliefs.

Marley's fame began to spread internationally after he signed a record contract with a British company in 1972. Leading several later versions of the Wailers, Marley spread reggae throughout the world, especially its message of political protest. Marley composed a number of reggae standards. His songs of political protest include "Exodus," "Zimbabwe," and "Rebel Music." He also performed lighter songs, such as "Stir It Up." He wrote "I Shot the Sheriff," which became a hit in a recording by Eric Clapton in 1974.

Marley died of cancer at the age of 36. His music was carried on by his children, notably his son David "Ziggy" Marley. Paul F. Wells



Marlin, *MAHR luhn,* is the name of a group of large, powerful game fishes that have a long, pointed bill. Their great strength and spectacular leaping ability make them a popular trophy fish.

Marlins are related to the swordfishes and sailfishes. Most grow 6 to 9 feet (1.8 to 2.7 meters) long and weigh 50 to 400 pounds (23 to 180 kilograms). But some marlins may reach 14 feet (4.3 meters) in length and weigh over 1,500 pounds (680 kilograms). The marlin's *dorsal* (back) fin looks like a sickle, and its tail is crescent-shaped.

Marlins live in the warm water near the ocean surface. *White marlins* live in the Atlantic Ocean. *Striped marlins* and *black marlins* live in the Pacific and Indian oceans. *Blue marlins* inhabit the Atlantic, Pacific, and Indian oceans. They eat mainly other fish and squid, which they stun by striking with their bill. Marlins may also use their bill to spear their prey.

People catch marlins mainly for sport. The fish are not an important human food. William J. Richards

Scientific classification. Marlins belong to the billfish family, Xiphiidae. The scientific name of the Atlantic blue marlin is

Marlowe, Christopher (1564-1593), was the first great Elizabethan writer of tragedy. His most famous work, *The Tragical History of Doctor Faustus* (about 1588), is an imaginative view of a legendary scholar's fall to damnation through lust for forbidden knowledge, power, and sensual pleasure. Never before in English literature had a writer so powerfully shown the soul's conflict with the laws defining the place of human beings in a universal order. See **Faust.**

Marlowe was born in February 1564 in Canterbury and studied at Cambridge. At some time during his university years, Marlowe did secret service work for the government. The few years before Marlowe's death in a tavern fight have left evidence of his duels and reports of his unconventional, skeptical political and religious thought.

Marlowe established his theatrical reputation with *Tamburlaine the Great* (about 1587). In "high astounding" poetry and spectacle, Marlowe wrote about an awe-inspiring conqueror, Tamburlaine. These plays reflect the widespread fascination in Marlowe's time with the reach and limits of the human will's desire for dominion. In *Tamburlaine,* Marlowe influenced later drama with his concentration on a heroic figure and his development of *blank verse* (unrhymed poetry) into a flexible poetic form for tragedy.

His later plays focus on what were considered the dangerous and subversive elements in Renaissance culture, such as atheism, witchcraft, and homosexuality. These plays are *The Jew of Malta* (c. 1589), *Edward II* (c. 1592), and *Doctor Faustus.* Marlowe's nondramatic poetry includes the unfinished *Hero and Leander,* which became an immediate classic; translations from the Roman poets Ovid and Lucan; and the pastoral lyric "The Passionate Shepherd to His Love." Stephen Orgel

Marmara, *MAHR muhr uh,* **Sea of,** is part of the trade waterway that links the Black Sea with the Mediterranean Sea. The Sea of Marmara was once called *Propontis.* The Bosporus, a strait, connects it with the Black Sea on the east. Another strait, the Dardanelles, links it with the Aegean Sea on the west.

The Sea of Marmara is about 170 miles (275 kilometers) long and 50 miles (80 kilometers) across at its widest point. It covers about 4,300 square miles (11,100 square kilometers). John J. Baxevanis

See also **Bosporus; Dardanelles; Turkey** (terrain map).

Marmoset, *MAHR muh zeht,* is one of the world's smallest kinds of monkey. Most marmosets are less than 1 foot (30 centimeters) long, not including the tail, and weigh from 10 to 12 ounces (300 to 350 grams). Their thick, soft coats range in color from silvery-white to dark gray or brown. Patches of hair stick out from the head and ears of some marmosets. Unlike most other monkeys, marmosets have claws instead of nails. They live in trees and walk on all four legs, like squirrels. Marmosets feed mainly on insects and fruit. They also chew holes in certain trees to eat the gum or sap. Most marmosets live in groups of three to eight in the tropical forests and woodland plains of Central and South America.

Rod Williams, Bruce Coleman Inc.

A pygmy marmoset feasts on a grape. Marmosets eat insects, fruit, and the gum or sap of trees.

There are 10 types of marmosets. The *pygmy marmoset* is $5\frac{1}{2}$ to $6\frac{1}{4}$ inches (14 to 16 centimeters) long and weighs between 5 and 7 ounces (150 and 200 grams). Pygmy marmosets are found from southern Colombia to southeastern Peru, and in parts of Ecuador and Brazil. Other marmosets live in Brazil and Bolivia.

Marmosets are kept as pets and are used in medical research. They are threatened by the increasing destruction of their tropical forest habitat. Roderic B. Mast

Scientific classification. Marmosets are members of the marmoset and tamarin family, Callitrichidae. The scientific name for the pygmy marmoset is *Cebuella pygmaea.* Other marmosets are in the genus *Callithrix.*

See also **Tamarin.**

Marmot, *MAHR muht,* is the largest member of the squirrel family. Marmots live in burrows and are found in much of the Northern Hemisphere. They are rodents. The woodchuck is a kind of marmot that lives in open areas (see **Woodchuck**).

North American marmots are from 1 to 2 feet (30 to 61 centimeters) long. They have short legs, small ears, and furry tails up to 9 inches (23 centimeters) long. Most marmots have gray fur on their backs and yellowish-orange fur on their bellies. Marmots eat plants. They grow fat in autumn and sleep through winter. Female marmots give birth to four or five young in May. Marmots live in *colonies* (groups) on mountain slopes.

Clyde Jones

Scientific classification. Marmots belong to the squirrel family, Sciuridae. The common marmot is *Marmota flaviventris.*

Marne, Battles of the. See **World War I** (The Western Front; The last campaigns).

Marne River, *mahrn,* is the largest branch of the Seine River in France. It rises in eastern France on the Langres Plateau and flows north and west for 310 miles (500 kilometers) through rich grain land. It empties into the Seine River southeast of Paris (see **France** [physical map]). Large barges can navigate the river. The Marne is linked to the east by a canal that runs through Nancy to Strasbourg on the Rhine River. Hugh D. Clout

Maroons is a term used to refer to runaway slaves who formed communities in North and South America from the early 1500's through the late 1800's. The term also refers to descendants of those slaves. The English word *maroon* comes from the Spanish word *cimarrón,* meaning *wild* or *untamed.* Maroon settlements once dotted the edges of plantation lands from the southern part of the United States to Brazil and Peru. The Maroons were skilled guerrilla fighters who often raided plantations for supplies. Some groups forced the colonial powers to sign treaties that granted them freedom.

Some Maroons formed powerful states with thousands of members. One of the best-known Maroon states, Palmares in northeastern Brazil, lasted for most of the 1600's (see **Palmares**). But other settlements survived less than a year. Today, Maroons still reside in semi-independent communities in several parts of North and South America. The most famous present-day Maroons are the Windward and Leeward Maroons of Jamaica and the Saramaka and Ndyuka Maroons of Suriname.

Richard Price

Marot, *ma ROH,* **Clement,** *klay MAHN* (1496?-1544), was a French poet who served in the households of King Francis I and Marguerite de Navarre. Marot composed light, elegant, witty verse that pleased the wealthy members of court society. But his poetry also reveals, with great artistry and devotion to truth, the social and intellectual realities of the time and an interest in the religious controversies of the Reformation. Shortly before his death, he published a significant translation of the Psalms. Some critics consider him an unimportant court poet. Others, especially modern critics, call him a genuine moralist who wrote with delicacy and discretion. Marot was born in Cahors. He died in Italy, exiled from Roman Catholic France because of his Protestant beliefs.

Robert B. Griffin

Marquand, *mahr KWAHND,* **John Phillips** (1893-1960), an American novelist, pictured the decayed aristocratic society in Boston with gentle but effective satire. He won the 1938 Pulitzer Prize for fiction for *The Late George Apley* (1937). This, and *Wickford Point* (1939); *H. M. Pulham, Esq.* (1941); and *Point of No Return* (1949) are usually considered his best works. They show how the inheritors of wealth conform to old customs without understanding the duties of a new age.

Marquand was born on Nov. 10, 1893, in Wilmington, Delaware. After graduating from Harvard University, he became a reporter for the Boston *Transcript.* Marquand won his first success as an author with romantic novels and with serialized detective stories about Mr. Moto, a secret agent. *Thirty Years* (1954) contains essays and reports on Marquand's own observations.

Bert Hitchcock

Marquesas Islands, *mahr KAY suhz,* are a group of about 10 volcanic islands in the South Pacific Ocean. The islands lie about 900 miles (1,400 kilometers) northeast of Tahiti and have a total area of 492 square miles (1,274 square kilometers). France governs them as part of the territory of French Polynesia (see **Pacific Islands** [map]).

The main islands in the Marquesas group are Hiva Oa, the largest island; Nuku Hiva; Ua Huka; and Ua Pou. The village of Tai o Hae, on Nuku Hiva, serves as the main port and administrative center. Most of the islands have steep mountains that drop sharply to the sea and fertile valleys with many streams and waterfalls. The Marquesas have a warm, humid climate, with an average temperature of about 78 °F (25 °C) throughout the year. Annual rainfall varies from about 50 inches (125 centimeters) to more than 100 inches (250 centimeters).

Victor Englebert

The island of Ua Pou is one of the largest of the Marquesas Islands. These volcanic islands are noted for their healthful climate and lush vegetation. Breadfruit and coconuts are chief crops.

About 7,000 people, mainly Polynesians, live on the Marquesas Islands. Most of them farm or fish to provide their own food. The chief crops are bananas, breadfruit, coconut, sweet potatoes, and taro. *Copra* (dried coconut meat) is the main export.

The first settlers on the Marquesas Islands arrived about 2,000 years ago. Historians are not sure whether these settlers came from Polynesia or South America. Remains of stone platform foundations for houses and large courtyards for religious ceremonies built by early settlers still exist. A Spanish explorer, Álvaro de Mendaña, reached the southernmost islands in 1595. He named them after the Marques de Mendoza, the Spanish viceroy of Peru. In 1791, Joseph Ingraham, an American sea captain, sailed among the northern islands.

Many American whalers visited the islands from the 1820's to the 1860's. Thousands of Marquesans died of diseases brought by the whalers. In 1842, France annexed the Marquesas Islands and stationed troops on Nuku Hiva. In 1870, France took control of all the Marquesas Islands. American author Herman Melville described the islands in his novel *Typee* (1846). The noted French painter Paul Gauguin spent the last two years of his life on Hiva Oa and is buried there.

Robert Langdon

Marquetry. See Inlay.

Marquette, *mahr KEHT,* **Jacques,** *zhahk* (1637-1675), was a French explorer and Roman Catholic missionary in North America. He joined the French-Canadian explorer Louis Jolliet on a trip down the Mississippi River. They were probably the first Europeans to explore the upper Mississippi and parts of Illinois and Wisconsin.

Early life. Marquette was born on June 1, 1637, in Laon, France, and attended schools run by Jesuit priests. He joined the Jesuit order in 1656 and studied and taught in France. In 1666, he was sent as a missionary to the French province, New France.

In New France, Marquette spent two years learning Indian languages. In 1668, he established a mission among the Ottawa Indians at Sault Sainte Marie in what is now Ontario. He went to the St. Esprit mission on Lake Superior in 1669 and worked among the Huron and Ottawa Indians. In 1671, he moved with them to the St. Ignace mission on northern Lake Michigan.

The Indians often talked about a great river called the Mississippi, a word that meant *big river* in their language. At that time, little was known about the geography of North America. Marquette and others thought the river might flow into the Pacific Ocean.

Exploration and discovery. Governor General Comte de Frontenac of New France believed the Mississippi might provide an easy route to the Far East for traders. In 1673, he sent Louis Jolliet to find the river and trace its course. Marquette knew some Indian languages, and so he was chosen to go with Jolliet.

In May 1673, Marquette, Jolliet, and five other men set out in two canoes from St. Ignace. They paddled south on Lake Michigan, into the Fox River, and up through what is now Wisconsin. They traveled overland from the Fox to the Wisconsin River. At the mouth of the Wisconsin, they saw the Mississippi.

The explorers paddled down the Mississippi and realized that it flowed south. They decided that the river probably flowed into the Gulf of Mexico, rather than into the Pacific Ocean. Along the way, they met many friendly Indians. But when the men reached the mouth of the Arkansas River, they encountered hostile Indians. A friendly Indian told Marquette that white people lived farther south on the river. The explorers realized these people must be Spaniards who had settled along the Gulf of Mexico. Marquette and Jolliet feared that the Indians and Spaniards would attack them. Having learned the course of the river, they turned back.

The expedition traveled up the Mississippi to the Illinois River and from there to the Kankakee River. They journeyed overland from the Kankakee to the Chicago River and on to Lake Michigan. Their journey had taken about five months.

WORLD BOOK map

Jacques Marquette was one of the first Europeans to explore the upper Mississippi River and nearby areas. In 1673, he made a historic trip down the river with the explorer Louis Jolliet.

Final journey. In 1674, Marquette set out from near present-day Green Bay, Wisconsin, to establish a mission among the Kaskaskia Indians near Ottawa, Illinois. But he became ill and spent the winter in a hut on the Chicago River. Marquette arrived in the spring of 1675, but his health became worse. He started out to St. Ignace for medical aid but died on the way.

Marquette University is an independent coeducational school in Milwaukee. It is sponsored by the Society of Jesus (Jesuits) and governed by a board composed of Jesuits and lay people. The university offers degrees in a variety of fields, including allied health fields, arts and sciences, business administration, communication, dentistry, education, engineering, journalism, law, nursing, and performing arts. The university has a graduate school and an evening division, and it also offers summer sessions.

Marquette was chartered in 1864 and opened in 1881. It became a university in 1907.

Critically reviewed by Marquette University

Marquis, *MAHR kwihs,* **Don** (1878-1937), was an American humorist and journalist. He became best known for his fictional creations archy the cockroach and his companion, mehitabel the alley cat. They first appeared in Marquis' daily newspaper column in 1916. archy typed accounts of his adventures with mehitabel on Marquis' typewriter at night. Because archy could not depress the shift key, he typed only in small letters, giving Marquis' columns a distinctive appearance. The cockroach mocked many subjects that irritated Marquis, including free verse, missionaries, organized labor, technology, and popular science writers. The cat ridiculed sober morality and pretentious social attitudes.

Marquis was born on July 29, 1878, in Walnut, Illinois. His full name was Donald Robert Perry Marquis. Marquis worked as a journalist in Atlanta, Georgia, from 1902 to 1909 and in New York City from 1909 to 1925. Marquis also wrote humorous verse, short stories, novels, and plays. William McKeen

Marrakech, *muh RAH kehsh* or *MAR uh KEHSH* (pop. 672,506), is one of the largest cities in Morocco. It is also one of the country's traditional capitals. Marrakech lies in west-central Morocco. For location, see **Morocco** (map). The city is noted for its *mosques* (Muslim houses of worship), parks, gardens, and pink clay buildings. Its chief industries include food processing, flour milling, and leather and textile manufacturing.

Marrakech was once the capital of a vast Berber empire. The city was founded by the Berber ruler Yusuf ibn Tashfin in 1062 and reached the height of its prosperity in the 1400's. Its importance declined when a succession of Arab rulers replaced the Berbers in Morocco.

A bride and groom exchange marriage vows at a wedding ceremony. Couples traditionally include a *best man* and a *maid of honor* in the ceremony to serve as official witnesses.

Marriage is the relationship between a man and a woman who have made a legal agreement to live together. When a man and woman marry, they become husband and wife. Marriage is also an important religious ceremony in many of the world's religions.

Most couples decide to marry because they love each other and want to spend the rest of their lives together. A man and woman who marry usually hope to share a special sexual relationship and a permanent romantic attraction. But each hopes the other will always be a close friend as well. Each also expects the other to help with many problems and to share certain responsibilities. These responsibilities include earning a living, budgeting money, paying bills, preparing meals, and taking care of a home.

Most couples who marry plan to have children and to raise them together. A husband and wife are required by law to protect and care for their children. Marriage thus serves as the basis of family life (see **Family**).

In the United States, about 2½ million couples marry each year. However, many people choose never to marry. Some people who remain single may not find a mate with whom they want to share their life. Others may not want the many responsibilities required of a successful marriage. Still others prefer to stay unmarried because they enjoy their independence.

Many married couples find they are not happy as husband and wife. Some marriages fail because the man and woman married when they were young and inexperienced in many ways. People who marry before they are 18 years old are much more likely to have unsuccessful marriages than if they had waited until they were older. A man and woman also have less of a chance of achieving a happy marriage if they marry primarily because the woman is pregnant. In addition, if a man and woman are of a different age, nationality, religion, or background, their chances of a successful marriage drop significantly.

In the United States, divorce has become common. Each year, more than a million American couples divorce. Most couples who divorce do so in the first 10 years of marriage. A majority of divorced people remarry, and many have a successful marriage with another partner. See **Divorce**.

Dating and courtship. In India and many other countries, most marriages are arranged by parents' deciding whom their children will marry. But in Western countries, including the United States and Canada, nearly everyone makes his or her own decision about whom and when to marry.

Before people marry, they date members of the opposite sex. A man and woman who date each other spend a great deal of time together learning to know the other person. After they have dated over time, they may find that they love each other and decide to become engaged.

In many cases, the man gives the woman an engagement ring as a token of their agreement to marry. The use of a ring as an engagement token comes from the ancient custom of using a ring to seal an important agreement.

The age at which people start to date varies widely. But generally, the younger that a man and a woman are

WORLD BOOK photo

Raising a family is one of the many rewards of marriage, but it is also a serious responsibility for the parents. The family shown above are enjoying a meal together at home.

The contributor of this article is Carlfred B. Broderick, Professor of Sociology at the University of Southern California.

© John Coletti, Stock, Boston

A husband and wife prepare a meal as a team. Many married couples today share household tasks that were traditionally handled by either the wife or the husband.

when they begin to date, the younger they are when they marry.

Most men and women date and marry people they live near, or with whom they work or go to school. Most people also date and marry those whom they consider attractive and who, in turn, regard them as attractive. In addition, people tend to date and marry individuals who are like themselves in certain ways. For example, people of the same nationality, ethnic group, and religion tend to marry each other. A man and woman are more likely to marry if they have similar social and educational backgrounds. They are also more likely to marry if they are about the same age.

Laws concerning marriage. A man and woman must follow certain laws when they marry. The United States and Canada have basically the same marriage laws. Neither nation has federal marriage laws, but each state and province has its own regulations.

In all except four states, both the man and woman must be at least 18 years old to marry without parental consent. Nebraska and Wyoming require a couple to be at least 19. Mississippi and Rhode Island have a minimum age of 21. Most states allow people to marry as young as 16 with parental consent. In some states, a person under age 16 needs a judge's permission to marry.

According to law, both the man and woman must freely consent to marry. If a person is forced or tricked into marrying against his or her will, a judge will *annul* (cancel) the marriage.

State laws prohibit close relatives from marrying each other. Laws also forbid a person to marry if he or she is married to someone else. A person who marries a second time while a first marriage is still in effect commits the crime of *bigamy.*

Some states permit a couple to marry even if the bride or groom cannot be present at the wedding ceremony. However, another person must serve as a *proxy* (substitute) for the absent bride or groom. This type of marriage is called *marriage by proxy.*

In nearly all states, a couple must have a marriage license to marry. Some states require both the man and the woman to have a blood test before they can obtain a marriage license. Several states test to determine if a person has syphilis, a sexually transmitted disease (see **Syphilis**). Other states test the blood for immunity to rubella. A few states require both tests. In some states, both the man and the woman must also have a medical examination before they can get a marriage license.

Most states require a waiting period of three to five days between the day a couple apply for a license and the day they marry. This period gives both people time to make sure they want to marry. The waiting period developed from a Roman Catholic custom that required a couple to announce their engagement publicly on each of the three Sundays before the wedding day. Between the first announcement and the wedding, anyone who believed that the couple should not marry was expected to say so. Today, some couples announce their engagement at church services or through church bulletins. Such announcements are called *banns.*

Marital status of the United States population

Source: U.S. Census Bureau.

If an unmarried couple live together as husband and wife, a court may declare them married after a certain period of time. The time period varies among the states that permit such *common-law marriages.* It is usually several years. A couple do not have to have a license or wedding ceremony for a common-law marriage.

Most states have laws forbidding people of the same sex to marry. However, many homosexual couples establish long-term relationships that are similar to marriage and consider themselves married. Some countries of Europe, as well as the state of Vermont, have passed laws that grant same-sex couples many of the same legal rights as husbands and wives. In September 2000, the Netherlands passed a law converting the country's registered same-sex partnerships into official marriages.

Wedding ceremonies and customs. Most wedding ceremonies involve two requirements. First, the man and woman must say that they want to become husband and wife. Second, the ceremony must have witnesses, including the official who marries the couple. If the couple have a religious ceremony, it is conducted by a member of the clergy, such as a minister, priest, or rabbi. If a couple are married in a *civil* (nonreligious) ceremony, a judge or some other authorized official performs it. During the days of long sea voyages, the captain of a ship was authorized to conduct a marriage ceremony while the ship was at sea.

Many couples prefer a traditional religious ceremony, though some people depart from custom. Some even write their own wedding service. A traditional marriage ceremony begins with the bridesmaids and ushers walking slowly down a center aisle to the altar. They stand on each side of the altar during the ceremony. The groom enters and waits for the bride at the altar. The bride then walks down the aisle with her father, another male relative, or a family friend. She wears a white dress and veil and carries a bouquet. At the altar, the bride and groom exchange marriage vows and accept each other as husband and wife. The groom puts a wedding ring on the ring finger of the bride's left hand, and the bride may also give the groom a ring. After the ceremony, the bride and groom kiss and then leave down the aisle.

People of many backgrounds follow the traditional wedding ceremony, but certain religious groups add their own features to it. For example, different Protestant groups have their own versions of the ceremony. Many Roman Catholic weddings take place during a Mass, and the bride and groom receive Holy Communion. Marriage is a *sacrament* (important religious ceremony) in the Roman Catholic and Eastern Orthodox churches (see Sacrament).

Most Jewish weddings are held under a special canopy that represents the couple's future home. At the end of the ceremony, an empty glass or other breakable object is placed on the floor and the groom breaks it with his foot. This act symbolizes the destruction of the ancient Jewish Temple in Jerusalem and reminds the couple that a marriage can also break if it is not protected.

Mormon weddings are held privately in Mormon temples. Only church members in good standing can attend these ceremonies. Mormons believe that marriage and family life continue after death.

A Quaker man and woman marry at a public gathering where they declare their commitment to each other.

J. M. Bertrand, Shostal

Some societies permit *polygamy,* the practice of having more than one wife or husband. This photograph shows a prince from the African country of Benin with five of his wives.

Quakers believe that God makes a couple husband and wife, and so a minister or other official is not required.

Many wedding customs have been popular since ancient times. For example, Roman brides probably wore veils more than 2,000 years ago. Bridal veils became popular in Britain and the New World during the late 1700's. The custom of giving a wedding ring dates back to the ancient Romans. The roundness of the ring probably represents eternity, and the presentation of wedding rings symbolizes that the man and woman are united forever. Wearing the wedding ring on the ring finger of the left hand is another old custom. People once thought that a vein or nerve ran directly from this finger to the heart. An old superstition says that a bride can ensure good luck by wearing "something old, something new, something borrowed, and something blue." Another superstition is that it is bad luck for a bride and groom to see each other before the ceremony on their wedding day.

The bride may toss her bouquet to the unmarried female guests. The woman who catches the flowers will supposedly be the next to marry. This custom probably started in France in the 1300's. The bride may also throw her garter to the unmarried men. The man who catches it will supposedly be the next male to marry.

Marriage problems. A man and woman expect certain things of each other even before they marry. After marriage, some husbands and wives cannot satisfy their partner's expectations. They may become disappointed and unhappy with each other and have problems with their marriage.

A couple may argue about almost anything, such as how to spend their money or how to treat their children. If they do not work out their differences, they may find it hard to be friends, romantic partners, or good parents.

Couples with marriage problems should seek help from a trained marriage counselor. Only a few states require marriage counselors to be licensed. A couple can obtain the names of qualified counselors in their area from the American Association for Marriage and Family

Therapy, which has headquarters in Washington, D.C.

Changing attitudes about marriage. Almost every society has certain traditional ideas about marriage. For example, most societies expect men and women to marry. In addition, most cultures have traditions about the role and the main duties of a husband and a wife. Traditionally, the husband is expected to earn a living, and the wife is expected to manage the household and raise children.

Many Americans disregard traditional marriage patterns. For example, a large number of married couples share responsibilities that have been traditionally handled by either the husband or the wife. An increasing number of married women have paying jobs and help support their families financially. In 1940, about 15 percent of all married women earned money. In the early 1990's, about 60 percent held a full- or part-time job. More and more husbands share responsibilities traditionally handled by women, such as cooking, doing housework, and caring for the children.

On the average, men and women stay single longer than they once did. In 1950, men married at an average age of 23, and women married at an average age of 20. By the mid-1990's, the average marriage age was about 26 $\frac{1}{2}$ for men and about 24 $\frac{1}{2}$ for women.

An increasing number of people choose not to marry. If a man and woman wish to avoid marriage, they may decide to live together with no formal obligations to each other. This arrangement is more common among young adults, but some couples of all ages live together without marrying.

Marriage in other cultures. In most countries, one man marries one woman, and they stay married unless one of them dies or they are divorced. This system of marriage is called *monogamy.* Some societies permit *polygamy,* in which a man has more than one wife, or a woman has more than one husband. The marriage of a man to more than one woman is called *polygyny* and is practiced by many African and Middle Eastern peoples. Islamic law permits a man to have as many as four wives. Some societies practice *polyandry,* the marriage of a woman to more than one man.

In certain cultures, marriage involves a gift from the family of the bride or groom to the other's family. In many societies, for example, the bride's family gives money or property to the groom or his family. Such a gift is called a *dowry.* In some cases, the dowry is given to the bride so that she and her husband may benefit from it. In other cultures, the groom and his family present gifts to the family of the bride. This offering is called a *bride price.*

Some societies require a person to marry someone who belongs to his or her own tribe or group. This custom is called *endogamy.* In other places, an individual must follow the rules of *exogamy* and marry a person from another tribe or village. The most common rule of exogamy requires a man or woman to marry someone outside his or her own family.

Each culture has its own rules about which family members a person is forbidden to marry. However, most societies forbid *incest,* which is marriage or sexual relations between certain close relatives. In nearly all cultures, such relatives include a parent and child or a brother and sister. Carlfred B. Broderick

Marryat, Frederick (1792-1848), was an English author whose novels about life at sea were widely read during the 1800's. Marryat's novels have declined in popularity, but they remain fine examples of adventure stories.

Marryat was born in London. As a boy, he tried to run away to sea several times. When Marryat was 14 years old, his father allowed him to join the Royal Navy. Marryat's 23 years of sea adventures in the Navy provided material for his writing. *The Naval Officer, or Scenes and Adventures in the Life of Frank Mildmay* (1829), for example, is largely an autobiographical novel.

Marryat's other sea novels include *The King's Own* (1830), *The Pirate and the Three Cutters* (1836), and *Mr. Midshipman Easy* (1836). Marryat also wrote children's stories. These works include *Masterman Ready* (1841-1842). K. K. Collins

Mars was the god of war in Roman mythology. The ancient Romans gave Mars special importance because they considered him the father of Romulus and Remus, the legendary founders of Rome.

Originally, Mars was a god of farmland and fertility. The month of March, which marked the beginning of the Roman growing season, was named for him. Since ancient times, the area enclosed by a bend in the Tiber River in Rome has been called the Field of Mars. The early Romans dedicated this section of land to Mars because of its fertility.

Mars became the god of war after the Romans came into contact with Greek culture. They gave him many characteristics of the Greek god of war, Ares. In time, the Romans associated Mars principally with war. Before going into battle, Roman troops offered sacrifices to him. After winning a battle, they gave Mars a share of their spoils. The word *martial,* which means *warlike,* is based on the god's name. The planet Mars is named for him.

Artists show Mars in armor and wearing a crested helmet. Editorial cartoonists still use this image of Mars as a symbol for war. The wolf and the woodpecker were associated with Mars. His love affair with Venus, the Roman goddess of love, became a popular subject for poets and painters. E. N. Genovese

NASA/JPL/Malin Space Science Systems

Mars, like Earth, has clouds in its atmosphere and a deposit of ice at its north pole. But unlike Earth, Mars has no liquid water on its surface. The rust-like color of Mars comes from the large amount of iron in the planet's soil.

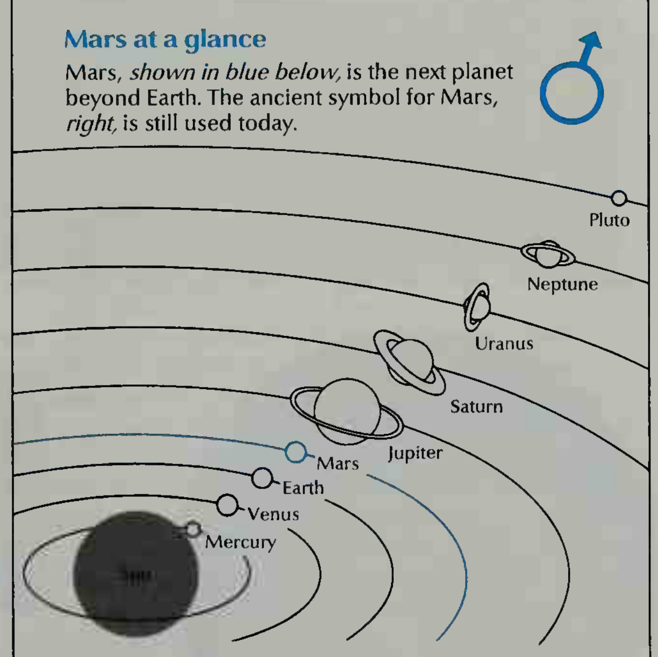
Mars

Mars is the fourth planet from the sun. The planet is one of Earth's "next-door neighbors" in space. Earth is the third planet from the sun, and Jupiter is the fifth. Like Earth, Jupiter, the sun, and the remainder of the solar system, Mars is about 4.6 billion years old.

Mars is named for the ancient Roman god of war. The Romans copied the Greeks in naming the planet for a war god; the Greeks called the planet Ares (pronounced *AIR eez).* The Romans and Greeks associated the planet with war due to its bloodlike color. Viewed from Earth, Mars is a bright reddish-orange. It owes its color to iron-rich minerals in its soil. This color is also similar to the color of rust, which is composed of iron and oxygen.

Scientists have observed Mars through telescopes based on Earth and in space. Space probes have carried telescopes and other instruments to Mars. Early probes were designed to observe the planet as they flew past it. Later, spacecraft orbited Mars and even landed there. But no human being has ever set foot on Mars.

Scientists have found strong evidence that water once flowed on the surface of Mars. The evidence includes channels, valleys, and gullies on the planet's surface. If this interpretation of the evidence is correct, water may still lie in cracks and pores in subsurface rock.



In addition, a group of researchers has claimed to have found evidence that living things once dwelled on Mars. That evidence consists of certain materials in meteorites found on Earth. But the group's interpretation of the evidence has not convinced most scientists.

The Martian surface has many spectacular features, including a canyon system that is much deeper and

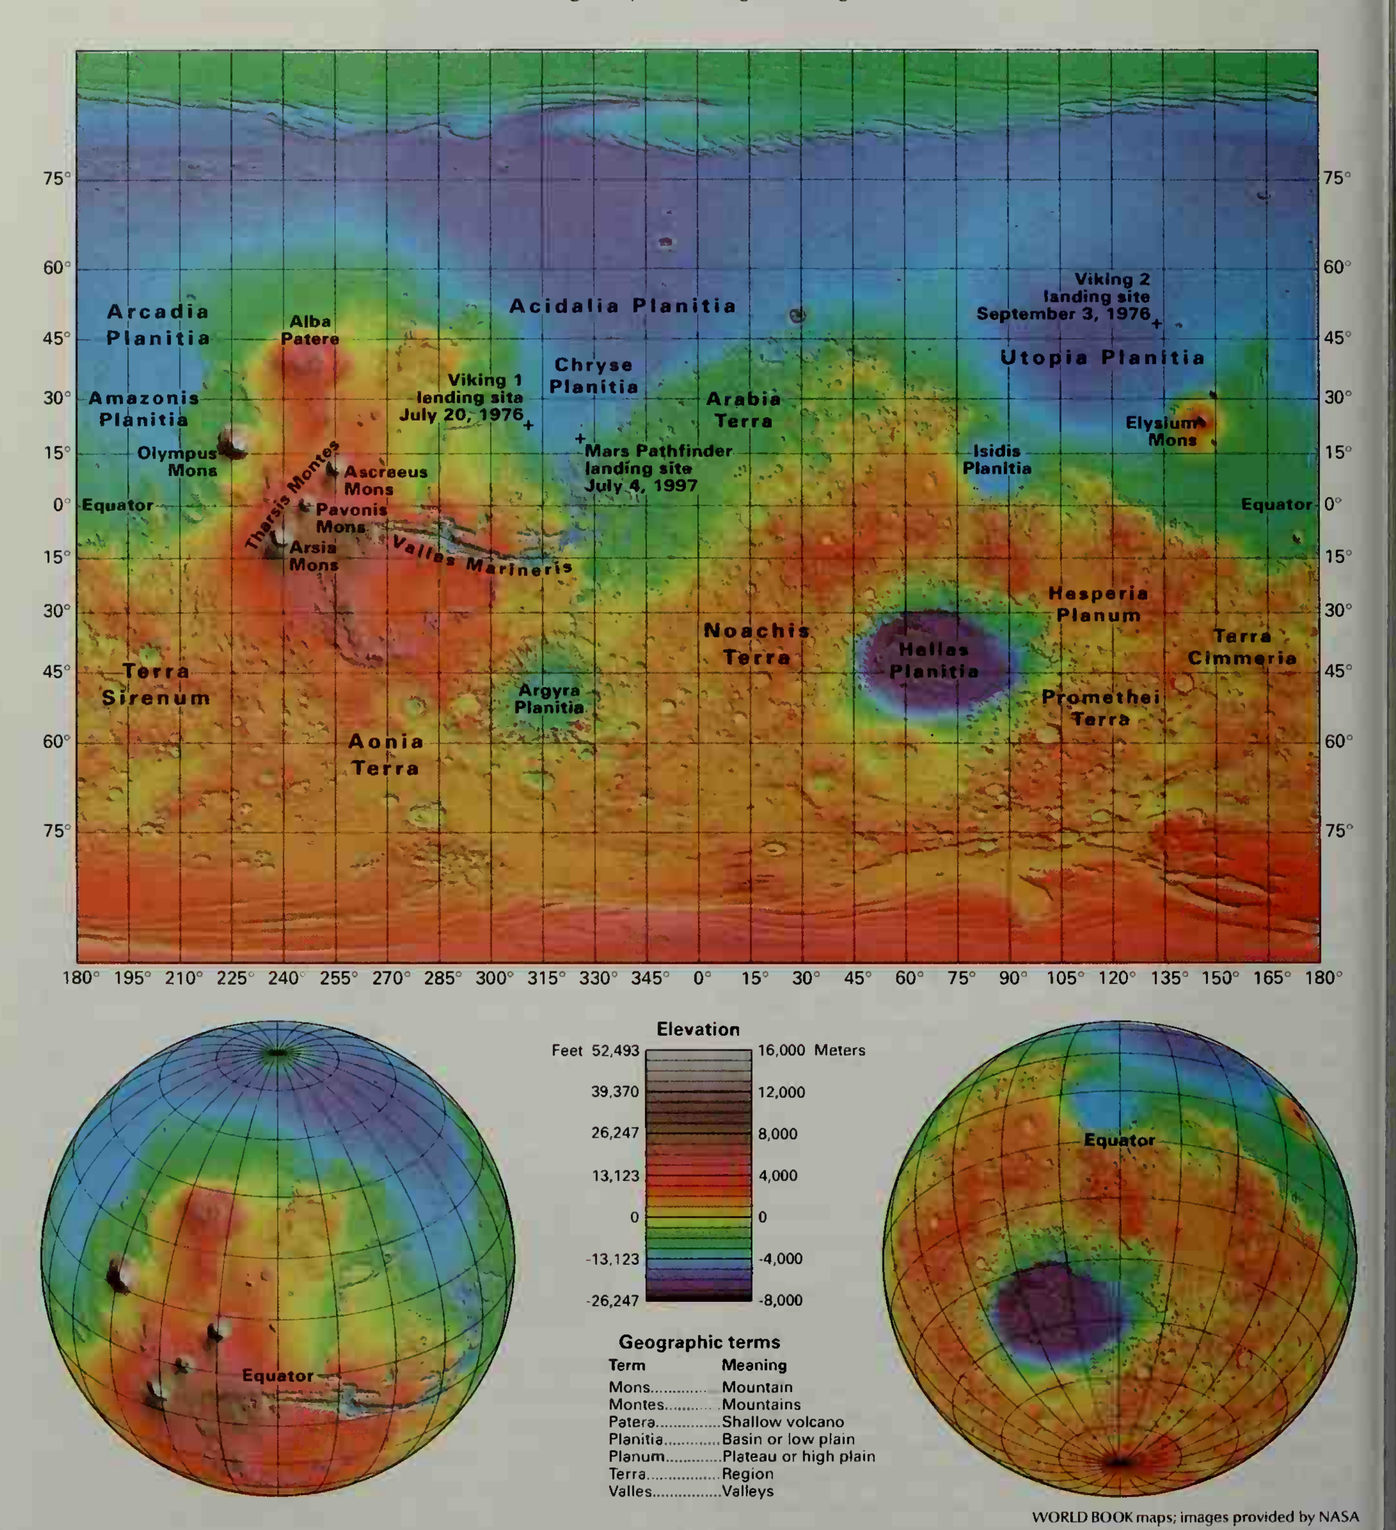
Mars at a glance



Mars, *shown in blue below,* is the next planet beyond Earth. The ancient symbol for Mars, *right,* is still used today.

Distance from the sun: *Shortest*—128,390,000 miles (206,620,000 kilometers); *Greatest*—154,860,000 miles (249,230,000 kilometers); *Average*—141,620,000 miles (227,920,000 kilometers).
Distance from Earth: *Shortest*—33,900,000 miles (54,500,000 kilometers); *Greatest*—249,000,000 miles (401,300,000 kilometers).
Radius: 2,107 miles (3,390 kilometers).
Length of year: 687 Earth days.
Length of solar day: 24 hours 39 minutes 35 seconds.
Temperature: −195 to 70 °F (−125 to 20 °C).
Atmospheric gases, most common: carbon dioxide, nitrogen, argon, oxygen, carbon monoxide, water vapor.
Number of satellites: 2.

The surface of Mars

Surface elevations shown on these maps were measured by the Mars Orbiter Laser Altimeter (MOLA), a device on the Mars Global Surveyor space probe. MOLA sent laser beams to the surface, then determined the heights by measuring how long the beams took to reach the surface and return.

WORLD BOOK maps; images provided by NASA

much longer than the Grand Canyon in the United States. Mars also has mountains that are much higher than Mount Everest, Earth's highest peak.

Above the surface of Mars lies an atmosphere that is about 100 times less dense than the atmosphere of Earth. But the Martian atmosphere is dense enough to support a weather system that includes clouds and winds. Tremendous dust storms sometimes rage over the entire planet.

Mars is much colder than Earth. Temperatures at the Martian surface vary from as low as about −195 °F (−125 °C) near the poles during the winter to as much as 70 °F (20 °C) at midday near the equator. The average temperature on Mars is about −80 °F (−60 °C).

Mars is so different from Earth mostly because Mars is much farther from the sun and much smaller than Earth. The average distance from Mars to the sun is about 141,620,000 miles (227,920,000 kilometers). This

distance is roughly $1\frac{1}{2}$ times the distance from Earth to the sun. The average *radius* (distance from its center to its surface) of Mars is 2,107 miles (3,390 kilometers), about half the radius of Earth.

Characteristics of Mars

Orbit and rotation. Like the other planets in the solar system, Mars travels around the sun in an *elliptical* (oval) orbit. But the orbit of Mars is slightly more "stretched out" than the orbits of Earth and most of the other planets. The distance from Mars to the sun can be as little as about 128,390,000 miles (206,620,000 kilometers) or as much as about 154,860,000 miles (249,230,000 kilometers). Mars travels around the sun once every 687 earth-days; this is the length of the Martian year.

The distance between Earth and Mars depends on the positions of the two planets in their orbits. It can be as small as about 33,900,000 miles (54,500,000 kilometers) or as large as about 249,000,000 miles (401,300,000 kilometers).

Like Earth, Mars rotates on its axis from west to east. The Martian *solar day* is 24 hours 39 minutes 35 seconds long. This is the length of time that Mars takes to turn around once with respect to the sun. The earthday of 24 hours is also a solar day.

The axis of Mars is not perpendicular to the planet's *orbital plane,* an imaginary plane that includes all points in the orbit. Rather, the axis is tilted from the perpendicular position. The angle of the tilt, called the planet's *obliquity,* is 25.19° for Mars, compared with 23.45° for Earth. The obliquity of Mars, like that of Earth, causes the amount of sunlight falling on certain parts of the planet to vary widely during the year. As a result, Mars, like Earth, has seasons.

Mass and density. Mars has a *mass* (amount of matter) of 7.08×10^{20} tons (6.42×10^{20} metric tons). The latter number would be written out as 642 followed by 18 zeroes. Earth is about 10 times as massive as Mars. Mars's *density* (mass divided by volume) is about 3.933 grams per cubic centimeter. This is roughly 70 percent of the density of Earth.

Gravitational force. Because Mars is so much smaller and less dense than Earth, the force due to gravity at the Martian surface is only about 38 percent of that on Earth. Thus, a person standing on Mars would feel as if his or her weight had decreased by 62 percent. And if that person dropped a rock, the rock would fall to the surface more slowly than the same rock would fall to Earth.

Physical features of Mars

Interior. Scientists do not yet know much about the interior of Mars. A good method of study would be to place a network of motion sensors called *seismometers* on the planet's surface. Those instruments would measure tiny movements of the surface, and scientists would use the measurements to learn what lies beneath. Researchers commonly use this technique to study Earth's interior.

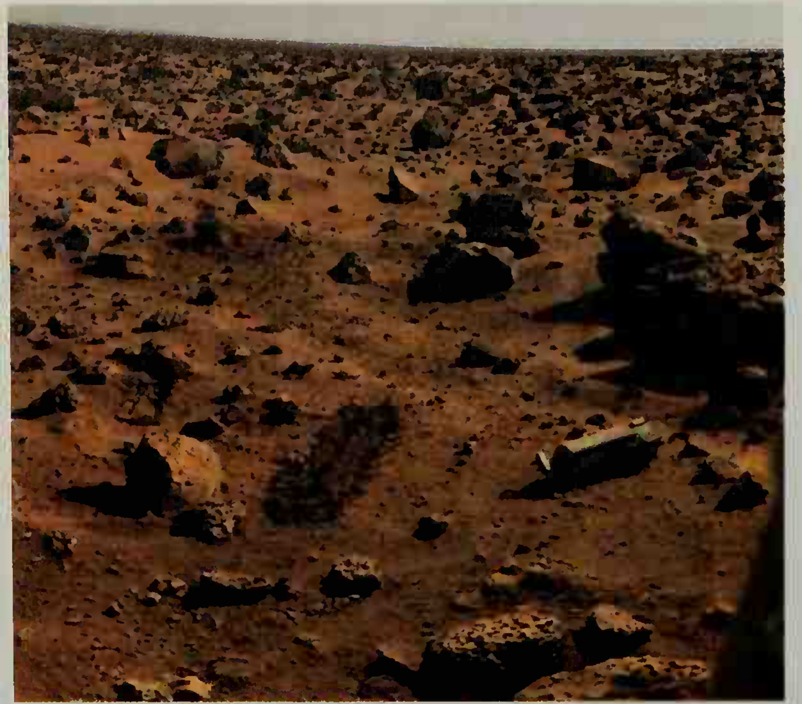
Scientists have four main sources of information on the interior of Mars: (1) calculations involving the planet's mass, density, gravity, and rotational properties; (2) knowledge of other planets; (3) analysis of Martian meteorites that fall to Earth; and (4) data gathered by orbiting space probes. They think that Mars probably has three main layers, as Earth has: (1) a crust of rock, (2) a mantle of denser rock beneath the crust, and (3) a core made mostly of iron.

Crust. Scientists suspect that the average thickness of the Martian crust is about 30 miles (50 kilometers). Most of the northern hemisphere lies at a lower elevation than the southern hemisphere. Thus, the crust may be thinner in the north than in the south.

Much of the crust is probably composed of a volcanic rock called basalt (pronounced *buh SAWLT).* Basalt is also common in the crusts of Earth and the moon. Some Martian crustal rocks, particularly in the northern hemisphere, may be a form of *andesite.* Andesite is also a volcanic rock found on Earth, but it has more *silica* than basalt does. Silica is a compound of silicon and oxygen.

Mantle. The mantle of Mars is probably similar in composition to Earth's mantle. Most of Earth's mantle rock is peridotite (pronounced *PEHR uh DOH tyt),* which is made up chiefly of silicon, oxygen, iron, and magnesium. The most abundant mineral in peridotite is olivine *(AHL uh veen).*

The main source of heat inside Mars must be the same as that inside Earth: *radioactive decay,* the breakup of the nuclei of atoms of such elements as uranium, potassium, and thorium. Due to radioactive heating, the average temperature of the Martian mantle may be roughly 2700 °F (1500 °C).



Core. Mars probably has a core composed of iron, nickel, and sulfur. The density of Mars gives some indication of the size of the core. Mars is much less dense than Earth. Therefore, the radius of Mars's core relative to the overall radius of Mars must be smaller than the radius of Earth's core relative to the overall radius of Earth. The radius of the Martian core is probably between 900 and 1,200 miles (1,500 and 2,000 kilometers).

Unlike Earth's core, which is partially *molten* (melted), the core of Mars probably is solid. Scientists suspect that the core is solid because Mars does not have a significant *magnetic field.* A magnetic field is an influence that a magnetic object creates in the region around it. If a planet's core is molten, motion within the core due to the planet's rotation makes the core a magnetic object.

Data from the Mars Global Surveyor space probe show that some of the planet's oldest rocks formed in the presence of a strong magnetic field. Thus, in the distant past, Mars may have had a hotter interior and a molten core.

Surface features. Mars has many of the kinds of surface features that are common on Earth. These include plains, canyons, volcanoes, valleys, gullies, and polar ice. But craters occur throughout the surface of Mars, while they are rare on Earth. In addition, fine-grained reddish dust covers almost all the Martian surface.

Plains. Many regions of Mars consist of flat, low-lying plains. Most of these areas are in the northern hemisphere. The lowest of the northern regions are among the flattest, smoothest places in the solar system. They may be so smooth because they were built up from deposits of *sediment* (tiny particles that settle to the bottom of a liquid). There is ample evidence that water once flowed across the Martian surface. The water would have tended to collect in the lowest spots on the planet and thus would have deposited sediments there.

NASA/National Space Science Data Center

The Martian surface was sampled for signs of life by the Viking 2 lander in 1976. A mechanical sampling arm dug the grooves near the round rock at the lower left. The cylinder at the right covered the sampling device and was ejected after landing. The cylinder is about 12 inches (30 centimeters) long.

Canyons. Along the equator lies one of the most striking features on the planet, a system of canyons known as the Valles Marineris. The name is Latin for *Valleys of Mariner;* a space probe called Mariner 9 discovered the canyons in 1971. The canyons run roughly east-west for about 2,500 miles (4,000 kilometers), which is close to the width of Australia or the distance from Philadelphia to San Diego. Scientists believe that the Valles Marineris formed mostly by *rifting,* a splitting of the crust due to being stretched.

Individual canyons of the Valles Marineris are as much as 60 miles (100 kilometers) wide. The canyons merge in the central part of the system, in a region that is as much as 370 miles (600 kilometers) wide. The depth of the canyons is enormous, reaching 5 to 6 miles (8 to 10 kilometers) in some places.

Large channels emerge from the eastern end of the canyons, and some parts of the canyons have layered sediments. The channels and sediments indicate that the canyons may once have been partly filled with water.

Volcanoes. Mars has the largest volcanoes in the solar system. The tallest one, Olympus Mons (Latin for *Mount Olympus),* rises 17 miles (27 kilometers) above the surrounding plains. It is about 370 miles (600 kilometers) in diameter. Three other large volcanoes, called Arsia Mons, Ascraeus Mons, and Pavonis Mons, sit atop a broad uplifted region called the Tharsis Montes.

All these volcanoes have slopes that rise gradually, much like the slopes of Hawaiian volcanoes. Both the Martian and Hawaiian volcanoes are *shield volcanoes.* They formed from eruptions of lavas that can flow for long distances before solidifying.

Mars also has many other types of volcanic landforms. These range from small, steep-sided cones to enormous plains covered in solidified lava. Scientists do not know how recently the last volcano erupted on Mars—some minor eruptions may still occur.

Craters and impact basins. Many meteoroids have struck Mars over its history, producing impact craters. Impact craters are rare on Earth for two reasons: (1) Those that formed early in the planet's history have eroded away, and (2) Earth developed a dense atmosphere, preventing meteorites that could have formed craters from reaching the planet's surface.

Martian craters are similar to craters on Earth's moon, the planet Mercury, and other objects in the solar systems. The craters have deep, bowl-shaped floors and raised rims. Large craters can also have central peaks that form when the crater floor rebounds upward after an impact.

On Mars, the number of craters varies dramatically from place to place. Much of the surface of the southern hemisphere is extremely old, and so has many craters. Other parts of the surface, especially in the northern hemisphere, are younger and thus have fewer craters.

Some volcanoes have few craters, indicating that they erupted recently. The lava from the volcanoes would have covered any craters that existed at the time of the eruptions. And not enough time has passed since the eruptions for many new craters to form.

Some of the impact craters have unusual-looking deposits of *ejecta,* material thrown out of the craters at impact. These deposits resemble mudflows that have solidified. This appearance suggests that the impacting bodies may have encountered water or ice beneath the ground.

Mars has a few large impact craters. The largest is Hellas Planitia in the southern hemisphere. *Planitia* is a Latin word that can mean *low plain* or *basin;* Hellas Planitia is also known as *the Hellas impact basin.* The crater has a diameter of about 1,400 miles (2,300 kilometers). The crater floor is about 5.5 miles (9 kilometers) lower than the surrounding plain.

Channels, valleys, and gullies occur in many regions of Mars, apparently as a result of water erosion. The most striking of these features are known as *outflow channels.* These channels can be as wide as 60 miles (100 kilometers) and as long as 1,200 miles (2,000 kilometers). They appear to have been carved by enormous floods that rushed across the surface. In many cases, the water seems to have escaped suddenly from underground.

Many of the channels do not look like river systems on Earth, with the main river formed from smaller rivers and streams. Rather, those Martian channels arise fully formed from low-lying areas.

Other regions of Mars have much smaller features called *valley networks.* These networks look more like river systems on Earth. Martian valley networks are up to a few miles or kilometers wide and up to a few hundred miles or kilometers long. The networks are mostly ancient features. They suggest that the Martian climate may once have been warm enough for water to exist as a liquid.

The gullies are smaller still. Most of them lie at high latitudes. They may be a result of a leakage of a small amount of ground water to the surface within the past few million years.

NASA/National Space Science Data Center

The Valles Marineris system of valleys is about 2,500 miles (4,000 kilometers) long—roughly one-fifth the distance around the planet. Parts of the system are 6 miles (10 kilometers) deep.

Polar deposits. The most interesting features in the polar regions of Mars are thick stacks of finely layered deposits of material. Scientists believe that the layers consist of mixtures of water ice and dust. The deposits extend from the poles to latitudes of about 80° in both hemispheres.

The atmosphere probably deposited the layers over long periods. The layers may provide evidence of seasonal weather activity and long-term changes in the Martian climate. One possible cause of climate changes is variation in the planet's obliquity. This variation alters the amount of sunlight falling on different parts of Mars. The variation in sunlight, in turn, may change the climate. Past climate changes could have affected the rate at which the atmosphere deposited dust and ice into layers.

Lying atop much of the layered deposits in both hemispheres are caps of water ice that remain frozen all year. The layers and overlying caps are several miles or kilometers thick.

In the wintertime, additional seasonal caps form from layers of frost. The seasonal caps are clearly visible through Earth-based telescopes. The frost consists of solid carbon dioxide (CO_2)—also known as "dry ice"—that has condensed from CO_2 gas in the atmosphere. In the deepest part of the winter, the frost extends from the poles to latitudes as low as 45°—halfway to the equator.

Atmosphere. The atmosphere of Mars contains much less oxygen (O_2) than that of Earth. The O_2 content of the Martian atmosphere is only 0.13 percent, compared with 21 percent in Earth's atmosphere. Carbon dioxide makes up 95.3 percent of the gas in the atmosphere of Mars. Other gases include nitrogen (N_2), 2.7 percent; argon (Ar), 1.6 percent; carbon monoxide (CO), 0.07 percent; and water vapor (H_2O), 0.03 percent.

Pressure. At the surface of Mars, the atmospheric pressure is typically only about 0.10 pound per square inch (0.7 kilopascal). This is roughly 0.7 percent of the atmospheric pressure at Earth's surface. When the seasons change on Mars, the atmospheric pressure at the surface there varies by 20 to 30 percent.

Each winter, the condensation of CO_2 at the poles removes much gas from the atmosphere. When this happens, the atmospheric pressure due to CO_2 gas decreases sharply. The opposite process occurs each summer. In addition, the atmospheric pressure varies as the weather changes during the day, much as on Earth.

Temperature. The atmosphere of Mars is coldest at high altitudes, from about 40 to 78 miles (65 to 125 kilometers) above the surface. At those altitudes, typical

NASA/JPL/Malin Space Science Systems

NASA/JPL/Malin Space Science Systems

Gullies in a crater wall, *left,* may have been created when underground water flowed out of the wall. The image at the left is a combination of photos taken by the Mars Orbiter Camera on the Mars Global Surveyor satellite. The photo above shows the location of the gullies relative to the entire crater, which is about 4 $\frac{1}{2}$ miles (7 kilometers) across. This crater is on the floor of the much larger Newton Crater in the southern hemisphere.

NASA/JPL

A sunset on Mars creates a glow due to the presence of tiny dust particles in the atmosphere. This photo is a combination of four images taken by Mars Pathfinder, which landed on Mars in 1997.

temperatures are below −200 °F (−130 °C). The temperature increases toward the surface, where daytime temperatures of −20 to −40 °F (−30 to −40 °C) are typical. In the lowest few miles or kilometers of the atmosphere, the temperature varies widely during the day. It can reach −150 °F (−100 °C) late at night, even near the equator.

Atmospheric temperatures can be warmer than normal when the atmosphere contains much dust. The dust absorbs sunlight and then transfers much of the resulting heat to the atmospheric gases.

Clouds. In the Martian atmosphere, thin clouds made up of particles of frozen CO_2 can form at high altitudes. In addition, clouds, haze, and fog composed of particles of water ice are common. Haze and fog are especially frequent in the early morning. At that time, temperatures are the lowest, and water vapor is therefore most likely to condense.

Wind. The Martian atmosphere, like that of Earth, has a *general circulation,* a wind pattern that occurs over the entire planet. Scientists have studied the global wind patterns of Mars by observing the motions of clouds and changes in the appearance of wind-blown dust and sand on the surface.

Global-scale winds occur on Mars as a result of the same process that produces such winds on Earth. The sun heats the atmosphere more at low latitudes than at high latitudes. At low latitudes, the warm air rises, and cooler air flows in along the surface to take its place. The warm air then travels toward the cooler regions at higher latitudes. At the higher latitudes, the cooler air sinks, then travels toward the equator.

On Mars, the condensation and evaporation of CO_2 at the poles influence the general circulation. When winter begins, atmospheric CO_2 condenses at the poles, and more CO_2 flows toward the poles to take its place. When spring arrives, CO_2 frost evaporates, and the resulting gas flows away from the poles.

Surface winds on Mars are mostly gentle, with typical speeds of about 6 miles (10 kilometers) per hour. Scientists have observed wind gusts as high as 55 miles (90 kilometers) per hour. However, the gusts exert much less force than do equally fast winds on Earth. The winds of Mars have less force because of the lower density of the Martian atmosphere.

Dust storms. Some of the most spectacular weather occurs on Mars when dust blows in the wind. Small, swirling winds can lift dust off the surface for brief intervals. These winds create *dust devils,* tiny storms that look like tornadoes.

Large dust storms begin when wind lifts dust into the atmosphere. The dust then absorbs sunlight, warming the air around it. As the warmed air rises, more winds occur, lifting still more dust. As a result, the storm becomes stronger.

At larger scales, dust storms can blanket areas from more than 200 miles (320 kilometers) to a few thousand miles or kilometers across. The largest storms can cover the entire surface of Mars. Such storms are unusual, but they can last for months. The strongest storms can block the whole surface from view.

Dust storms are most common when Mars is closest to the Sun. More storms occur then because that is when the sun heats the atmosphere the most.

Satellites. Mars has two tiny moons, Phobos and Deimos. The American astronomer Asaph Hall discovered them in 1877 and named them for the sons of Ares. Both satellites are irregularly shaped. The largest diameter of Phobos is about 17 miles (27 kilometers); that of Deimos, about 9 miles (15 kilometers).

The two satellites have many craters that formed when meteoroids struck them. The surface of Phobos also has a complicated pattern of grooves. These may be cracks that developed when an impact created the satellite's largest crater.

Scientists do not know where Phobos and Deimos formed. They may have come into existence in orbit around Mars at the same time the planet formed. Another possibility is that the satellites formed as asteroids near Mars. The gravitational force of Mars then pulled them into orbit around the planet. The color of both satellites is a dark gray that is similar to the color of some kinds of asteroids.

Evolution of Mars

Periods of evolution. Scientists know generally how Mars evolved after it formed about 4.6 billion years ago. Their knowledge comes from studies of craters and other surface features. Features that formed at various stages of the planet's evolution still exist on different parts of the surface. Researchers have developed an evolutionary scenario that accounts for the sizes, shapes, and locations of those features.

Researchers have ranked the relative ages of surface regions according to the number of impact craters observed. The greater the number of craters in a region, the older the surface there.

However, scientists have not yet determined exactly when the various evolutionary stages occurred. To do that, they would need to know the ages of rocks of surface features representing those stages. They could determine how old such rocks are if they could analyze samples of them in a laboratory. But no space probe has ever brought Martian rocks to Earth.

Scientists have divided the "lifetime" of Mars into three periods. From the earliest to the most recent, the periods are: (1) The Noachian (pronounced *noh AY kee uhn)*, (2) the Hesperian, and (3) the Amazonian. Each period is named for a surface region that was created during that period.

The Noachian Period is named for Noachis Terra, a vast highland in the southern hemisphere. During the Noachian Period, a tremendous number of rocky objects of all sizes, ranging from small meteoroids to large asteroids, struck Mars. The impact of those objects created craters of all sizes. The Noachian was also a time of great volcanic activity.

In addition, water erosion during the Noachian Period probably carved the many small valley networks that mark Mars's surface. The presence of those valleys suggests that the climate may have been warmer during the Noachian Period than it is today.

The Hesperian Period. The intense meteoroid and asteroid bombardment of the Noachian Period gradually tapered off, marking the beginning of the Hesperian Period. This period is named for Hesperia Planum, a high plain in the lower latitudes of the southern hemisphere.

During the Hesperian Period, volcanic activity continued. Volcanic eruptions covered over Noachian craters in many parts of Mars. Most of the largest outflow channels on the planet are of Hesperian age.

The Amazonian Period, which is characterized by a low rate of cratering, continues to this day. The period is named for Amazonis Planitia, a low plain that is in the lower latitudes of the northern hemisphere.

NASA/JPL

Mars Global Surveyor studied the composition of the Martian surface, photographed the surface in detail, and measured its elevation. The space probe went into orbit around Mars in 1997.

Volcanic activity has occurred throughout the Amazonian Period, and some of the largest volcanoes on Mars are of Amazonian age. The youngest geologic materials on Mars, including the ice deposits at the poles, are also Amazonian.

Possibility of life. Mars might once have harbored life, and living things might exist there even today. Mars almost certainly has three ingredients that scientists believe are necessary for life: (1) chemical elements, such as carbon, hydrogen, oxygen, and nitrogen, that form the building blocks of living things; (2) a source of energy that living organisms can use; and (3) liquid water.

The essential chemical elements likely were present throughout the planet's history. Sunlight could be the energy source, but a second source of energy could be the heat inside Mars. On Earth, internal heat supports life in the deep ocean and in cracks in the crust.

Liquid water apparently carved Mars's large channels, its smaller valleys, and its young gullies. Thus, water apparently has existed near the surface over much of the planet's history. And water is probably present beneath the surface today, kept liquid by Mars's internal heat.

In 1996, a team led by David S. McKay, a geologist at the National Aeronautics and Space Administration's Johnson Space Center in Houston, reported that scientists there had found evidence of microscopic Martian life. They discovered this evidence inside a meteorite that had made its way to Earth. The meteorite had been blasted from the surface of Mars, almost certainly by the impact of a much larger meteorite. The small meteorite had then journeyed to Earth, attracted by Earth's gravity. The trip may have taken millions of years.

The evidence included complex organic molecules, grains of a mineral called *magnetite* that can form within some kinds of bacteria, and tiny structures that resemble fossilized microbes. The scientists' conclusions are controversial, however. There is no general scientific agreement that Mars has ever harbored life.

History of Mars study

Observation from Earth. Observing Mars through Earth-based telescopes, early astronomers discovered polar caps that grow and shrink with the seasons. They also found light and dark markings that change their shape and location.

In the late 1800's, the Italian astronomer Giovanni V. Schiaparelli reported that he saw a network of fine dark lines. He called these lines *canali,* which is Italian for *channels.* But *canali* was generally mistranslated as *canals.* Many other astronomers also reported seeing such features. Among those observers was the American astronomer Percival Lowell, who referred to the features as canals. Lowell speculated that the canals had been built by a Martian civilization.

The canals turned out not to exist. In some cases, the observers had misinterpreted dark, blurry regions that they had actually seen. In other cases, there was no relationship between "canals" and real features.

However, the changing dark and light markings were real. Some scientists thought that the changing patterns might result from the growth and death of vegetation. Much later, other scientists suspected correctly that the cause was the Martian winds. Light and dark materials blow to and fro across the surface.

Observation by spacecraft. Robotic spacecraft began detailed observation of Mars in the 1960's. The United States launched Mariner 4 to Mars in 1964 and Mariners 6 and 7 in 1969. Each flew by Mars about half a year after its launch. The craft took pictures showing that Mars is a barren world, with craters like those on the moon. There was no sign of liquid water or life. The spacecraft observed few of the planet's most interesting features because they happened to fly by only heavily cratered regions.

In 1971, Mariner 9 went into orbit around Mars. This craft mapped about 80 percent of Mars. It made the first discoveries of the planet's canyons and volcanoes. It also found what appear to be dry riverbeds.

The next major mission to Mars was Viking, launched by the United States in 1975. Viking consisted of two orbiters and two landers. Its main goal was to search for life. The orbiters scouted out landing sites for the landers, which touched down in July and September 1976. The landers took the first close-up pictures of the Martian surface, and they sampled the soil. They found no strong evidence for life.

The next two successful probes were Mars Pathfinder, which was a lander, and Mars Global Surveyor, an orbiter. The United States launched both craft in 1996. The main objective of Pathfinder was to demonstrate a new landing system. Inflated air bags cushioned the probe's landing in July 1997. Pathfinder also carried a small roving vehicle called Sojourner. The rover rolled down a ramp to the surface, and then moved from rock to rock. Pathfinder sent spectacular photos back to Earth, and Sojourner analyzed rocks and soil. People throughout the world watched television pictures of Sojourner doing its work.

Mars Global Surveyor carried a group of sophisticated scientific instruments. A laser altimeter used laser beams to determine the elevation of the Martian surface. This instrument produced maps of the entire surface that are accurate to within 1 yard or meter of elevation. An infrared spectrometer determined the composition of some of the minerals on the surface. A high-resolution camera revealed a host of new geologic features. These include layered sediments that may have been deposited in liquid water, and small gullies that appear to have been carved by water.

NASA/Johnson Space Center

A curved, rodlike structure shown in the center of this photo has been referred to as a fossilized Martian creature by some scientists. The structure is about 200 billionths of a meter long and is part of a Martian rock that was found on Earth.

In April 2001, the United States launched the Mars Odyssey probe. The probe carried instruments to analyze the chemical composition of the Martian surface and the rocks just below the surface, to determine whether there is water ice on or beneath the surface, and to study the radiation near Mars. In February 2002, the probe found evidence that there is much water ice below the surface. The probe indicated that most of the ice is south of 60° south latitude. Steven W. Squyres

Mars Pathfinder was a United States spacecraft that transmitted images and other data from the surface of Mars for nearly three months in 1997. On July 4, 1997, Pathfinder "bounced down" on the Ares Vallis flood plain of Mars. It "bounced" because part of its mission was to test a new landing system that used parachutes and air bags rather than the traditional rockets. Just before landing, the air bags inflated to completely enclose the spacecraft. This cushioning enabled Pathfinder to land in a rocky, boulder-filled valley that would have severely damaged a conventional spacecraft.

After landing, Pathfinder released Mars Sojourner Rover, a small, six-wheeled robot that analyzed the rocks and soil on Mars. The Pathfinder mission returned more than 16,500 images to scientists on Earth, including spectacular color pictures of Mars's surface and views

NASA/JPL

The Sojourner Rover examines a rock on Mars. The rover traveled from Earth aboard the Mars Pathfinder space probe, then rolled down a ramp to the surface. Sojourner is only 24 $\frac{3}{4}$ inches (63 centimeters) long.

of the planet's moons and the sun from Mars. Pathfinder identified volcanic rocks that scientists had not expected to find on Mars. It also found that a cloud layer covers the Martian sky in the morning. Daniel Britt

See also Mars (Observation by spacecraft).

Marsalis, Wynton (1961-), an American trumpeter and composer, has won acclaim both as a jazz and a classical musician. He is one of the most influential figures in jazz. His style is based on a knowledge of jazz tradition and mastery of technique. In 1991, he became artistic director of the Jazz at Lincoln Center program in New York City. Marsalis was the first jazz composer to win a Pulitzer Prize in music, receiving the 1997 award for his oratorio *Blood on the Fields* (1996).

Marsalis was born on Oct. 18, 1961, in New Orleans. His music teachers included his father, Ellis Marsalis, a respected pianist. At the age of 14, Wynton performed the Trumpet Concerto by Joseph Haydn with the New Orleans Symphony Orchestra. Marsalis made his first commercial recordings in 1980 as a member of Art Blakey's Jazz Messengers. Since then, Marsalis has performed with his own small groups and with jazz and classical orchestras. Frank Tirro

Marseillaise, *MAHR suh LAYZ,* is the national hymn of France. Claude Joseph Rouget de Lisle, a French army engineer, wrote the words and the music in Strasbourg on April 25-26, 1792. He wrote the hymn as a marching song after France declared war on Austria and Prussia.

The fighting against Austria and Prussia occurred during the French Revolution (1789-1799). Rouget de Lisle supported the monarchy. His song, however, became a rallying cry of the revolutionary leaders and the common people. It became associated with the revolution when soldiers from Marseille sang it in August 1792 as they marched to storm the Tuileries, a palace in Paris where King Louis XVI lived. From this time on, the song was called "The Marseillaise." It was officially adopted as the national hymn in 1879. Valerie Woodring Goertzen

Marseille, *mahr SAY* (pop. 807,071; met. area pop. 1,349,772), is the second largest city in France and the country's main seaport. Paris is the only larger French city. Marseille, the nation's oldest city, lies on the Mediterranean Sea (see **France** [political map]).

The city extends inland from an old port that is too small for modern ships. This port, called Old Harbor, is filled with pleasure boats and surrounded by restaurants and cafes. The Canèbiere, a main street lined with modern shops, extends inland from Old Harbor.

A huge, modern port—one of the world's busiest—lies west of Old Harbor. Trading ships from many parts of the world dock at the port. Crew members of the ships visit the city and give it a busy, international flavor. Marseille also has attracted many workers from other countries, especially the countries of northern Africa.

Marseille has many beautiful churches. Notre-Dame-de-la-Garde has a large image of the Virgin Mary on its tall steeple that can be seen far out at sea.

Economy of Marseille is based on trade and manufacturing. The city's port handles about a third of the traffic of all French seaports. About 4,500 ships use the port annually. Industries in the area process chemicals, food, and petroleum from many parts of the world. The city's chief manufactured products include bricks, candles, engines, medicines, soap, and tiles.

History. Marseille was founded about 600 B.C. by Greek adventurers from Asia Minor, who called it *Massalia.* Marseille was an independent city until the first century before the birth of Christ. It then came under Roman domination and fell into decline. In the Middle Ages, the city regained its importance during the Crusades, a series of Christian military expeditions to recapture the Holy Land from the Muslims. Many soldiers and supplies were sent through the port to the Holy Land.

Provence, the region where Marseille is located, became part of France in 1481. Bloody struggles took place in Marseille in the late 1700's during the French Revolution. The opening of the Suez Canal in 1869 provided a water route between the Mediterranean Sea and Indian Ocean. The canal greatly increased the city's importance as a shipping center. William M. Reddy

For the monthly weather in Marseille, see **France** (Climate). See also **Marseillaise.**

Marsh is a type of wetland where nonwoody plants, such as cattails, grow. Trees and shrubs are not commonly found in marshes. Many kinds of animals make their homes in marshes, including muskrats, turtles, frogs, red-winged blackbirds, and dragonflies.

There are two kinds of marshes—*freshwater marshes* and *salt marshes.* Freshwater marshes develop where the water level is above the surface of the ground for most, if not all, of the year. They generally occur along the shores of lakes, ponds, rivers, and streams where the water is shallow. Plants commonly found in freshwater marshes include bulrushes, horsetails, and reeds.

Salt marshes lie along coasts where fresh water flows into the sea—for example, at river mouths. They are thus exposed to both fresh and salt water, and they experience daily changes in water level due to tidal activity. Grasses, especially cordgrass and salt-meadow grass, are often the most abundant plants in salt marshes.

Many marshes have been destroyed to make way for buildings and roads or have been damaged by water pollution. Public awareness of the ecological importance of marshes has led to the protection and preservation of many of them. Despite this awareness, a number of marshes are eliminated each year. Eric F. Karlin

Marsh, Ngaio, *NY oh* (1899-1982), was a famous New Zealand-born author of detective fiction. Marsh created the character of Roderick Alleyn, an upper-class English police officer who works in Scotland Yard. She intro-

duced Alleyn in *A Man Lay Dead* (1934). He appeared in 31 more novels.

Several Alleyn mysteries draw on the author's background as a stage actress, producer, and director in New Zealand. These novels include *Enter a Murderer* (1935), *Night at the Vulcan* (1951), *Killer Dolphin* (1966), and *Light Thickens* (1982, the last Alleyn mystery). Even those novels not actually set in theaters usually describe murders during some kind of performance. Although most of Marsh's books have a London background, she used her New Zealand homeland in the Alleyn novels *Vintage Murder* (1937), *Colour Scheme* (1943), *Died in the Wool* (1945), and *Photo Finish* (1980).

Edith Ngaio Marsh was born in Fendalton, now part of Christchurch, New Zealand. Queen Elizabeth II made her Dame Commander of the Order of the British Empire in 1966. Jon L. Breen

Marsh, Reginald (1898-1954), was an American artist famous for his realistic pictures of New York City life. He excelled at portraying crowds on skid row or Coney Island, on subways or in burlesque houses. Some of his scenes have a grim feeling of the Great Depression of the 1930's. But most are full of vitality. Marsh worked in various painting media, often experimenting with the techniques and materials used by the great painters before 1700. He was also an accomplished draftsman.

Marsh was born in Paris of American parents and grew up in New Jersey. After graduating from Yale University, he was an illustrator for the New York *Daily News.* He taught at the Art Students League in New York from the early 1930's until his death. Charles C. Eldredge

Marsh mallow is a plant that grows in meadows and marshes of eastern Europe. It is now grown in the United States. The marsh mallow has woody stalks, which grow 2 to 4 feet (61 to 120 centimeters) high, and large leaves. Downy hair covers both stalks and leaves. The plant has bluish to pink flowers. Its root is white and shaped like a carrot. People have eaten the roots and leaves of the plant during famines. These parts also are sometimes used for medicinal purposes. Walter S. Judd

Scientific classification. The marsh mallow belongs to the mallow family, Malvaceae. It is *Althaea officinalis.*

Marshal is the highest title in the armies of many countries. A *marshal* is also a police officer having the same powers and duties as a sheriff in many towns or villages.

In England, the word *marshal* was used to mean *commander of the army* as early as the 1100's. The countries of Europe have given the title *marshal* to top-ranking military commanders. Joseph Stalin, dictator of the Soviet Union, used the title *Marshal* in World War II (1939-1945). The British Army uses the title *field marshal,* and the head of the British air forces is called an *air marshal.*

In the United States, officers of the federal court are called *United States marshals.* They open and close sessions of district courts and courts of appeals, and may serve writs, orders, and other processes of the courts in their districts. *Deputy United States marshals* can make arrests for violation of federal laws. A United States marshal is assigned to each federal court district.

Temporary police are sometimes called marshals, and in some towns the head of the fire department is called the *fire marshal.* Jack M. Kress

Marshall, Alfred (1842-1924), was a British educator and the most influential economist of his day. He combined two different theories about what determines the value or price of a good. "Classical" theorists had said price was determined mainly by the cost of producing the good, and theorists of the late 1800's had stressed the *utility* (usefulness) of the good and the consumer demand for it. In *Principles of Economics* (1890), Marshall said that all of these factors helped determine price.

Marshall believed that a self-regulating economy, free of major government interference and based on competition and private enterprise, would lead to better social conditions, a fair distribution of income, and full employment. His emphasis on consumer welfare led to the development of *welfare economics.* This branch of economics judges economic systems by how well they contribute to consumer satisfaction and human well-being.

Marshall was born in London. He taught economics at Oxford and Cambridge universities. Daniel R. Fusfeld

Marshall, George Catlett (1880-1959), an American soldier and statesman, served as chief of staff of the United States Army during World War II (1939-1945). He also served as secretary of state from 1947 to 1949 and as secretary of defense in 1950 and 1951. Marshall was the first professional soldier to become secretary of state. In 1947, while serving in that post, he proposed the European Recovery Program, also called the Marshall Plan. Under this plan, the United States spent billions of dollars to rebuild war-torn western Europe. The Marshall Plan is credited with helping check the spread of Communism in Europe. Marshall's role in European reconstruction earned him the 1953 Nobel Peace Prize.

His early life. Marshall was born on Dec. 31, 1880, in Uniontown, Pennsylvania. His father owned coal and coke properties. The senior Marshall was extremely proud of his distant cousin John Marshall, former chief justice of the United States (see **Marshall, John**).

Marshall graduated from the Virginia Military Institute in Lexington, Virginia, in 1901. He was not an outstanding student, but he ranked in the upper half of his class. He received an army commission as a second lieutenant of infantry in 1902. Marshall married Elizabeth Carter Coles in 1902. She died in 1927, and Marshall married Katherine Tupper Brown in 1930.

His early career. Marshall began his Army career in the Philippines in 1902. He returned home in 1903 and attended the Army School of the Line and the Army Staff College at Fort Leavenworth, Kansas. He graduated first in his class from the School of the Line.

Assigned to the Philippines again in 1913, he showed great ability for planning in mock battles. In 1916, he returned home and was promoted to captain. After the United States entered World War I in 1917, Marshall sailed for France with the first field units to go overseas. He served for a year as training officer and then as chief of operations of the First Division. He was transferred to the First Army in 1918 and served as chief of operations in the closing months of the war.

Marshall helped plan the First Army's attack on St.-Mihiel. He directed the movement of more than 400,000 men and 2,700 guns from St.-Mihiel to the Meuse-Argonne front for the final American battle of the war.

This transfer, made at night in less than two weeks, completely surprised the Germans.

Marshall served as senior aide to General John J. Pershing, the commander of the U.S. forces, from 1919 to 1924. From 1924 to 1927, he served in China as executive officer of the 15th Infantry Regiment.

From 1927 until 1932, Marshall was assistant commandant in charge of training at the Infantry School, Fort Benning, Georgia. He later helped organize and administer Civilian Conservation Corps (CCC) camps.

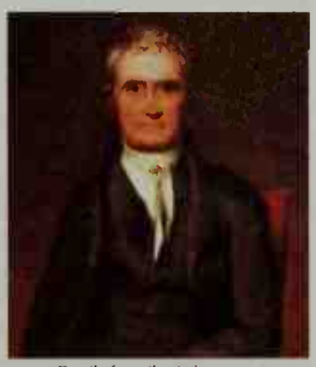
World War II. Marshall was made a brigadier general in 1936. In 1938, he became chief of the war plans division of the War Department and then deputy chief of staff of the Army. On Sept. 1, 1939, the day World War II began, he became chief of staff of the U.S. Army, which then had fewer than 200,000 men, including the Army Air Corps. He also became a four-star general.

Marshall helped make the U.S. Army the greatest fighting force in history. He organized the Army into units trained to take part in desert, mountain, and jungle warfare. His work in Washington, D.C., was so important that he remained there throughout the war. He helped plan the overall war strategy. He was responsible for building, arming, and supplying a force of 8,250,000 soldiers and airmen. Under Marshall's command, General Dwight D. Eisenhower and General Douglas MacArthur led American forces to victory in Europe and the Pacific.

On Dec. 16, 1944, Marshall became a General of the Army. In November 1945, a few months after the war ended, he retired as chief of staff. President Harry S. Truman later appointed him special representative to China.

Statesman. Marshall returned to the United States in January 1947, to assume the post of secretary of state in President Truman's Cabinet. As secretary, he urged Congress to pass the European Recovery Program. Under the plan, the United States sent about $13 billion in aid to European countries. Marshall also worked to secure aid for Greece and Turkey and to supply food to West Berlin when the Communists blockaded that city. These programs and the Marshall Plan did much to check Communist influence in Europe (see **Marshall Plan**). Marshall also began negotiations that led to the North Atlantic Treaty Organization (NATO). In 1949, he resigned his Cabinet post because of poor health.

Marshall served as president of the American Red Cross in 1949 and 1950. When the Korean War began in 1950, Truman asked Marshall to head the Department of Defense. Marshall helped build up the United Nations fighting forces in Korea. He resigned as secretary of defense in September 1951.



Marshall died on Oct. 16, 1959, and was buried at Arlington National Cemetery. In 1964, the George C. Marshall Research Library, containing his papers and souvenirs, opened in Lexington, Virginia. Theodore A. Wilson

Marshall, James Wilson (1810-1885), discovered gold in California on Jan. 24, 1848. He found pieces of gold while building a sawmill for John Sutter 48 miles (77 kilometers) north of Sutter's Fort. News of the discovery started the gold rush of 1849. In spite of his discovery, Marshall died a poor and bitter man. The first people who came to the gold site paid a small fee, but later arrivals refused to pay. The claims of Marshall and Sutter were swept aside. Marshall was born on Oct. 8, 1810, in Hunterdon County, New Jersey. Dan L. Flores

Marshall, John (1755-1835), the fourth chief justice of the United States, established the Supreme Court as an important branch of the federal government. He served from 1801 until his death in 1835, longer than any other chief justice. Marshall is known as the "Great Chief Justice" due to his great impact on the U.S. judicial system.

When Marshall became chief justice, the Supreme Court commanded little respect. Marshall raised the court to a level equal to the executive and legislative branches of the government. He used the court's authority to restructure and clearly define the boundaries of power between the states and the federal government. He established broad judicial principles. Some of these principles laid the foundation for the court's later rulings in such areas as civil rights and criminal justice.

During Marshall's years as chief justice, Democratic-Republicans and Democrats governed the country. Most of these leaders—President Thomas Jefferson, in particular—believed in states' rights. But Marshall was a Federalist. He thought the United States greatly needed a strong central government. He felt that such a government—rather than strong state governments—could best help the country grow strong and safe. Through the force of his arguments, Marshall gave the court the power to overrule the states when national and state interests collided.

Detail of an oil painting on canvas (about 1832) by William James Hubbard; National Portrait Gallery, Smithsonian Institution, Washington, D.C.

John Marshall

Early life. Marshall was born on Sept. 24, 1755, in a log cabin near Germantown, Virginia. His mother was related to Thomas Jefferson. His father served in the Virginia House of Burgesses and as a county sheriff. John helped to raise his 14 younger brothers and sisters on the family farm. He had little formal schooling.

Marshall joined the Continental Army in 1776, during the Revolutionary War in America. He spent the winter of 1777-1778 with General George Washington's forces at Valley Forge, and he was promoted to captain in 1778. In 1780, Marshall studied law briefly at the College of William and Mary and was admitted to the Virginia bar.

Political career. In 1782, Marshall was elected to his first term in the Virginia legislature and moved to Richmond. That same year, he became a member of the Council of State, the executive branch of government in Virginia. In 1783, Marshall married Mary Willis Ambler of Richmond. He resigned from the Council of State in 1784, when it was decided he could not practice law at the same time. However, Marshall quickly regained his seat in the state legislature and continued his distinguished legal career. In 1788, Marshall was elected to the state convention called to decide whether to *ratify* (approve) the proposed Constitution of the United States. He helped win ratification by Virginia.

Marshall served several more terms in the Virginia legislature until 1797, when he became a U.S. minister to France under President John Adams. Adams sent Marshall and two other ambassadors to Paris to negotiate .

with the French government over French interference with American trade. When Marshall returned in 1798, he was hailed as a hero for refusing to give in to unreasonable and somewhat dishonorable French demands in what became known as the XYZ Affair (see **XYZ Affair**). Marshall was elected to the U.S. House of Representatives in 1799. He quickly became the leader of the moderate Federalists and championed the policies of President Adams. This position made him a rival of his distant cousin and fellow Virginian, Thomas Jefferson, and the two men seldom agreed from then on. In 1800, Adams appointed Marshall secretary of state.

Chief justice. In January 1801, as Adams's term neared a close, he named Marshall chief justice of the United States. The U.S. Senate quickly confirmed the nomination, and Marshall took the position on Feb. 4, 1801. Marshall believed that the Constitution, upon which the national government was based, must be accepted as the supreme law of the land.

In 1803, Marshall wrote the opinion in the landmark case of *Marbury v. Madison.* In this case, the Supreme Court struck down an act of Congress that was in conflict with the Constitution. The decision firmly established the court's power to declare laws unconstitutional, a power known as *judicial review.* Afterward, Marshall used the power of his position to persuade his fellow justices to accept his view of the Constitution and the need for a strong judiciary and a strong central government, especially in the area of commerce. President Thomas Jefferson and his fellow Democratic-Republicans feared that the Supreme Court would use its power to help the Federalists weaken the states. However, judicial review strengthened the Constitution and remained one of the Supreme Court's greatest powers.

The *Marbury v. Madison* ruling opened the way for a series of landmark Supreme Court decisions. One of the most important cases in the court's history was *McCulloch v. Maryland* (1819). The court ruled that Congress possessed *implied powers*—that is, powers not specifically stated in the Constitution. In this case, Marshall upheld the power of Congress to create the United States Bank and ruled that the state of Maryland's attempt to tax the bank was unconstitutional. This decision was crucial to the growth of the United States because it allowed for changes in the needs of the nation over time. It also firmly established the superiority of federal power over state power in case of conflict.

In the case of *Fletcher v. Peck* (1810), Marshall established that the Constitution protects contracts against interference from the states. In this case, the court declared a state law unconstitutional for the first time. By the time Marshall died, the judicial branch of the federal government had become equal in authority with the executive and legislative branches. Charles T. Cullen

Hobson, Charles F. *The Great Chief Justice: John Marshall and the Rule of Law.* Univ. Pr. of Kans., 1996.
Smith, Jean E. *John Marshall.* Henry Holt, 1996.

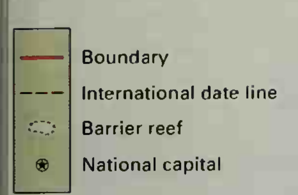
Marshall, Thomas Riley (1854-1925), served as vice president of the United States from 1913 to 1921, under President Woodrow Wilson. He made the famous remark: "What this country needs is a good 5-cent cigar." He served two terms as vice president, but had little influence in the Wilson administration. He was the first vice president to preside at a Cabinet meeting in the absence of the president. In 1919, after Wilson became seriously ill, Marshall refused to listen to those who urged him to declare himself president. He was born in North Manchester, Indiana, on March 14, 1854, and graduated from Wabash College. He practiced law and was governor of Indiana from 1909 to 1913. Kendrick A. Clements

See also **Vice President of the U.S.** (picture).

Marshall, Thurgood (1908-1993), was the first African American justice on the Supreme Court of the United States. He was appointed by President Lyndon B. Johnson in 1967 and served until 1991, when he retired because of ill health.

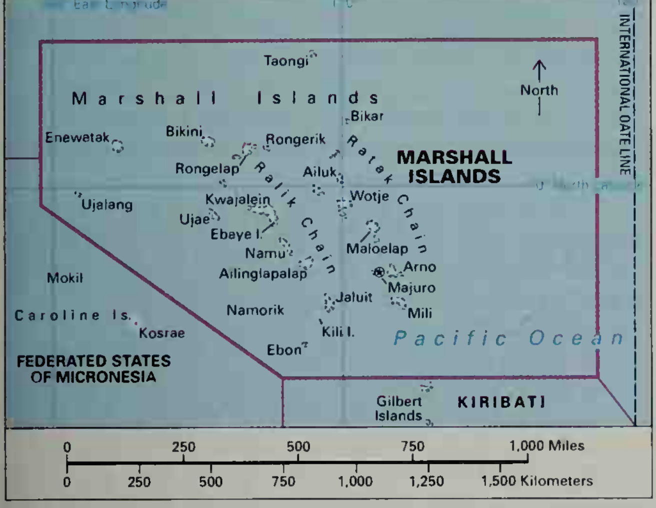
As a justice, Marshall wrote a number of important decisions on freedom of expression and on equal protection, urging the court to safeguard the rights of minorities and the poor. He also argued that capital punishment could not be administered in a way that met the Constitution's requirements. As conservative justices became the majority on the court, Marshall often expressed dissenting views in eloquent written opinions.

Thurgood Marshall



Marshall was born in Baltimore on July 2, 1908. He graduated from Lincoln University and studied at Howard University School of Law. He began private law practice in Baltimore in 1933 but soon joined the legal department of the National Association for the Advancement of Colored People (NAACP). He served as the NAACP's chief legal officer from 1938 to 1950 and as director and chief counsel for the NAACP Legal Defense and Educational Fund from 1940 to 1951. He coordinated the organization's lawsuits challenging segregation in housing and education. He was the primary strategist of the series of cases that ended with the Supreme Court's 1954 decision in the case of *Brown v. Board of Education of Topeka* that segregation in public schools is unconstitutional (see **Brown v. Board of Education of Topeka**).

President John F. Kennedy appointed Marshall to the U.S. Court of Appeals in New York in 1961. Marshall served until 1965, when President Johnson named him solicitor general of the United States. Marshall died on Jan. 24, 1993. He is buried in Arlington National Cemetery in Arlington, Virginia. Mark Tushnet



Marshall Islands is a country in the North Pacific Ocean. It consists of 29 ring-shaped strips of land called *atolls* and 5 tiny islands. The country has a total land area of only about 70 square miles (181 square kilometers). But the land is scattered over about 780,000 square miles (2,020,000 square kilometers) of ocean.

The United States gained control of the Marshall Islands in 1944. Although the Marshalls now form an independent country, the United States is responsible for the country's defense. The atoll of Majuro is the capital. The

Marshall Islands

WORLD BOOK maps

U.S. dollar serves as the basic unit of currency. The nation's official name is Republic of the Marshall Islands. The national anthem is "Forever Marshall Islands." See **Flag** (picture: Flags of Asia and the Pacific).

Government. The Marshall Islands is a parliamentary democracy. The parliament, called the *Nitijela,* has 33 members, who are elected by the people. The Nitijela elects a president from among its members. The president appoints cabinet ministers to handle government operations. The 12-member Council of *Iroij* (traditional chiefs) reviews legislation affecting customary law.

People. Most of the people of the Marshall Islands are Micronesians (see **Pacific Islands** [Micronesia]). About half of the country's approximately 68,000 people live on Majuro Atoll. Another 20 percent reside on Ebeye Island in Kwajalein Atoll. The rest of the people are scattered among the mostly rural outer islands. The country's official languages are Marshallese and English.

Life in the country's urban areas has begun to resemble life in the United States. Residents depend heavily on food, clothing, and other goods imported from the United States and other countries. Most people live in simple wooden or cement houses with iron roofs. Electric power, telephones, and televisions are common.

A more traditional way of life continues in rural areas. Rural men provide food by fishing and raising such crops as breadfruit, arrowroot, pandanus, and coconuts. They build small thatched houses or wooden houses with tin roofs. Rural women run the household, prepare meals, care for children, and make handicrafts. Most people are Christians, but some follow the Bahá'í faith.

Land and climate. Most of the country is made up of atolls, which consist of clusters of coral islets and strips of land surrounding a lagoon. The climate is hot and humid. The average temperature is about 81 °F (27 °C). Average annual rainfall is 80 inches (200 centimeters) in the north and 160 inches (410 centimeters) in the south.

Economy. The chief employers in the Marshall Islands are the country's national government and a United States missile base on Kwajalein Atoll. Coconuts rank as the main agricultural product. *Copra* (dried coconut meat) and handicrafts are the chief manufactured products. Tourism is a small, but growing, industry.

History. The first people to settle on the islands probably came from Southeast Asia between A.D. 500 and 1200. In the early 1500's, Spanish explorers became the first Europeans to arrive. The Marshall Islands are named for British Captain John Marshall, who saw the islands in 1788 as he sailed from Australia to China.

Germany gained control of the Marshalls in 1886. Japan took them over in 1914, at the beginning of World War I. In 1944, during World War II, the United States invaded the islands and defeated the Japanese in battles at Kwajalein and Enewetak atolls. In 1947, the United States began administering the islands as part of the United Nations Trust Territory of the Pacific Islands. Between 1946 and 1958, the U.S. military tested nuclear weapons on Bikini and Enewetak atolls. Before the testing, the inhabitants had been resettled on other islands as a safety measure. For further details, see **Bikini Atoll; Enewetak.**

The Marshall Islands adopted its own constitution in 1979. In 1986, the United States granted independence to the Marshall Islands. Under a Compact of Free Association, the United States retained use of the missile testing range at Kwajalein Atoll. In return, the United States agreed to defend the Marshall Islands and provide economic aid. Michael R. Ogden

Marshall Plan encouraged European nations to work together for economic recovery after World War II (1939-1945). In June 1947, the United States agreed to administer aid to Europe if the countries would meet to decide what they needed. The official name of the plan was the European Recovery Program. It is called the Marshall Plan because Secretary of State George C. Marshall first suggested it.

The Marshall Plan began in April 1948, when Congress established the Economic Cooperation Administration (ECA) to administer foreign aid. Seventeen nations formed the Organization for European Economic Cooperation (OEEC) to assist the ECA. The United States sent about $13 billion in food, machinery, and other products to Europe. Aid ended in 1952.

In 1961, the Organization for Economic Cooperation and Development (OECD) succeeded the OEEC. Twenty nations, including the United States and Canada, formed the OECD to promote the economic growth of member nations and aid developing areas. Theodore A. Wilson

Marston, John (1576-1634), was an English playwright. Two of his plays reflect the pessimism of their time, when the glories of the Elizabethan Age were becoming clouded by the uncertainties of life in the 1600's. *Antonio's Revenge* (1600) is a sensational drama of revenge about the murder of a tyrant. With *Hamlet,* it is among the first examples of tragedy in English drama. *The Malcontent* (1604) is a somber comedy of intrigue, bitter in its satire but intended to correct, not to condemn.

Marston was probably born in Coventry. His talent for satire led to a quarrel with Ben Jonson. He was briefly imprisoned in 1608 for critical comments about King James I. Later, Marston studied theology and in 1616 became rector of a country parish. Albert Wertheim

Marsupial is a mammal whose young are born in an extremely immature state. The newborn undergoes most of its development attached to one of its mother's nipples and nourished by her milk. Marsupial females usually have a *marsupium* (pouch) to protect the babies.

There are about 270 species of marsupials, all of which live in either the Americas or Australasia. They include kangaroos, opossums, and the koala. Marsupials inhabit many environments, including forests, plains, and deserts. Kangaroos are the biggest marsupials. Male red kangaroos can stand about 6 feet (1.8 meters) tall. The smallest marsupials are the shrewlike ningauis, some of which weigh less than $\frac{1}{10}$ ounce (3 grams).

Characteristics of marsupials. Marsupials differ from other mammals by giving birth to extremely underdeveloped young. Most mammals give birth to relatively well-developed offspring. Such mammals are called *placentals.* At the other extreme are *monotremes,* which lay eggs. See Mammal (Reproduction).

At birth, a marsupial is expelled from the birth canal near the base of its mother's tail. It wiggles along the mother's fur until it reaches the nipples. The newborn marsupial attaches itself to a nipple and begins to nurse. The nipple expands in the youngster's mouth, so there is little danger of separation. A young marsupial stays attached to its mother's nipples for several months. Then it separates itself from its mother but continues to stay close to her. The young of tree-dwelling marsupials, such as possums and the koala, cling to their mother's back after they have left the pouch. They remain there until they no longer need the mother's milk.

Marsupials also differ from placentals in the details of their skeleton. Marsupials possess two bones, called the *marsupial bones* or *epipubic bones,* that extend forward from the pelvis. No placental has this skeletal feature.

© Tom McHugh, Photo Researchers

A marsupial mother commonly carries its young in a pouch. This picture shows a wallaby mother and her offspring.

Kinds of marsupials. There are seven *orders* (major groups) of marsupials. Three are native to the Americas. Plant-eating opossums make up one of the American groups. The common opossum is the only marsupial found north of Mexico. Other opossums live in Central and South America. Another American group contains the *caenolestids,* also called the rat opossums or shrew opossums. They live in western South America and eat mostly insects and other invertebrates. The third American group consists of one species, the *monito del monte.* This small nocturnal mammal eats mostly insects.

The remaining four marsupial orders are native to Australia, New Guinea, and nearby islands. *Dasyurids* are mostly small, insect-eating animals. But this order also includes such larger species as the meat-eating quolls and Tasmanian devil.

Diprotodonts make up a wide variety of plant-eating marsupials. One group of diprotodonts, the *macropods,* include kangaroos and wallabies. These grass-eating animals have hind legs larger than their front legs. Other diprotodonts are called *possums,* but they should not be confused with opossums of the Americas. Most possums live in trees and eat mainly fruits, flowers, and nectar. Some possums evolved as gliders. Two well-known types of diprotodonts, the wombats and the koala, are closely related. Wombats are burrowers and eat mainly grasses. The tree-dwelling koala eats eucalyptus leaves.

The last two orders of Australasian marsupials are the bandicoots and the marsupial mole. Most bandicoots have long, pointed noses that they use to root in the soil for insects. The burrowing marsupial mole resembles a true mole. It eats mostly insects and worms.

History of marsupials. Scientists believe marsupials originated on a large continent that later split into smaller pieces. The marsupials remained on only two of the pieces, which are now South America and Australia. Many American marsupials became extinct due to competition with placentals. But the Australian species flourished because they were isolated from most placentals.

Many Australian marsupials face extinction. They are threatened by human destruction of their habitat and by such animals as foxes, rabbits, and dingoes, which were brought to Australia by human beings. Michael L Augee

Scientific classification. Marsupials make up seven different orders in the class Mammalia.

Marsupial cat. See Quoll.

Marsupial mouse is the common name for various small Australian mammals. These mammals resemble mice but are not mice at all. They are *marsupials,* mammals that give birth to very underdeveloped young. The young are carried in a pouch on the mother's body until they develop more completely. Unlike real mice, marsupial mice eat meat. They belong to a group of marsupials called *dasyurids,* which includes the Tasmanian devil.

WORLD BOOK illustration by Rachel Lockwood, WILDlife Art Ltd.

The ningaui, a marsupial mouse, is the smallest marsupial.

Marsupial mice live throughout Australia. One group, ningauis, are the smallest known marsupials. Adult ningauis measure about 2 inches (5 centimeters) long and weigh as little as $\frac{1}{10}$ ounce (3 grams). Another group, called dunnarts or narrow-footed marsupial mice, have large ears and narrow feet. The kultarr, also known as the jerboa marsupial mouse, has long hind legs.

Although small in size, marsupial mice are fierce predators. They hunt at night, feeding mostly on insects but occasionally eating such larger animals as lizards or house mice. In some species, the males live for only one year and die after mating. Females give birth to between 6 and 12 young. Michael L. Augee

Scientific classification. Marsupial mice belong to the dasyurid family, Dasyuridae. Ningauis make up the genus *Ningaui,* dunnarts are in the genus *Sminthopsis,* and the kultarr is *Antechinomys laniger.*

Martel, Charles. See Charles Martel.

Marten is a slim, fur-covered mammal that looks like an oversized weasel. It lives in mountainous and forested areas of Asia, Europe, and North America.

The best-known North American species is the *American marten.* It is fairly common in the Rocky Mountains and the Far North from Labrador and Quebec to Alaska. This marten has thick, golden-brown fur with darker feet and a paler face. It usually has an orange patch on the throat and chest. It grows to 26 inches (66 centimeters) long, including its tail. Martens weigh 2 to 3 pounds (0.9 to 1.4 kilograms). The males are slightly larger than the females. The American marten eats mice, rabbits, squirrels, and birds. It lives in hollow trees and rock crevices. About nine months after mating, the female gives birth, usually to two or three young.

Joe Van Wormer, Bruce Coleman Inc.

The marten is a member of the weasel family.

From November to March, when the American marten's coat is thick and soft, trappers in Canada and the United States kill about 50,000 to 130,000 animals. The fur is used in coats, hats, and muffs.

The *fisher* is related to the American marten. A male fisher weighs up to 20 pounds (9 kilograms). It has dark brown or grayish-brown fur. Now rare, the fisher is found in the same areas as the American marten. It lives on the ground or in trees. It eats mostly small rodents. It also feeds on porcupines and snowshoe hares. Well-known European martens include the *beech marten,* which has white fur on its throat and chest, and the *pine marten,* with yellow fur on these parts. Charles A. Long

Scientific classification. Martens are in the weasel family, Mustelidae. The American marten is *Martes americana.* The fisher is *M. pennanti;* the beech, *M. foina;* and the pine, *M. martes.*

Martha's Vineyard, an island 4 miles (6 kilometers) off the southeastern coast of Massachusetts, is a popular summer resort. Vineyard Sound separates it from the mainland. The island covers about 100 square miles (260 square kilometers). For location, see **Massachusetts** (physical map). Its attractions include a mild climate, beaches, fishing, shopping, and yachting. About 15,000 people live on the island. Explorer Bartholomew Gosnold named the island for his daughter and for the grapevines he found there in 1602. Laurence A. Lewis

Martí, *mahr TEE,* **José Julián** (1853-1895), was a Cuban political activist, journalist, and author. He was devoted to achieving Cuba's independence from Spain. Martí was killed during a battle with the Spaniards.

Martí was a leader in the Modernist movement in Spanish literature (see **Latin-American literature** [Modernism]). Martí's writing is marked by rhythmic flow and an original choice of words. His poetry and especially his prose represent an effort by the Modernists to give literary Spanish a new beauty. His poetry collections *Ismaelillo* (1882) and *Simple Verses* (1891) attempt to move beyond the romanticism of the time. His eloquent political writings were influential in Spanish America. Martí was born on Jan. 28, 1853, in Havana. He lived in exile in the United States from 1881 to 1895. Naomi Lindstrom

Martial, *MAHR shuhl* (A.D. 40?-104?), was an ancient Roman writer. He became famous for developing the *epigram* into its modern form—a sharp, stinging poem or saying (see **Epigram**). Martial wrote more than 1,500 short verses and epigrams. They contain witty and sometimes obscene comments about the vices of ancient Roman society. He also wrote several serious pieces, including one on the death of a slave girl named Erotion, whom he loved. Martial's full name was Marcus Valerius Martialis. He was born in Bilbilis, Spain. He came to Rome in A.D. 64. Elaine Fantham

Martial arts, *MAHR shuhl,* is a general term for various types of fighting arts that originated in Asia. Most martial arts practiced today came from China, Japan, and Korea. There are hundreds of martial arts, each divided into specific *styles* or *systems.*

Technically, the martial arts fall into two categories, *percussive* and *nonpercussive.* In percussive martial

arts, such as *karate-do* (pronounced *kuh RAH tee doh)* and *tae kwon do (TY kwahn DOH)*, people kick and strike with their hands, feet, elbows, knees, and head. Nonpercussive martial arts involve throwing, locking, and neutralizing the opponent without striking him or her. *Judo* and *aikido (eye KEE doh)* are the most popular martial arts in this category. See **Judo; Karate; Tae kwon do.**

Weapons are often used in advanced training in martial arts to preserve ancient tradition. But in some martial arts, weapons are part of the basic training.

Today, people practice the martial arts for exercise, as a means of self-defense, and as a sport. Martial sports have many variations, from judo and traditional karate, in which blows are pulled short of contact, to kickboxing or full-contact karate, in which the objective is to win by knockout, as in professional boxing. See **Kickboxing.**

Chinese martial arts are called *kung fu (kuhng foo)* in the West. In China, they are known as *wushu (woo shoo).* Kung fu, a general term for hundreds of Chinese martial arts, means *skill* or *ability.* Kung fu represents systems created for combat, health and exercise, or dance. The most popular styles are *Shaolin (shah oh LIHN)* and *t'ai chi ch'uan (ty jee chwahn)*, also spelled *taijiquan.* Shaolin developed in northern China and involves straight-line attacks and retreats, emphasizing strength and speed. T'ai chi ch'uan, the southern style, consists of circular motions and intricate foot patterns and emphasizes gentle force and inner harmony. See **T'ai chi ch'uan.**

The origins of kung fu are unknown. Some historians believe it started as early as the 1500's B.C. Kung fu reached the West in the mid-1800's, with the first migration of Chinese laborers to the United States. Many were skilled in kung fu and restricted its teachings to those of immediate Chinese ancestry. This custom ended in 1964, when a kung fu instructor in Los Angeles opened his school to non-Chinese.

Japanese martial arts. Two major martial arts evolved in Japan, the *bujutsu (boo JUHT soo)*, or "ancient martial arts," and the *budo*, or "new martial ways." Although their philosophies differ, both schools are based on spiritual concepts found in Zen Buddhism and Shinto. Bujutsu emphasizes combat and willingness to face death as a matter of honor. It contains the philosophy and techniques of the Japanese samurai warriors and includes such arts as *jujutsu (joo JUHT soo)* and *karate-jutsu (kuh RAH tee JUHT soo).* Budo, which started during the late 1800's, focuses on moral and aesthetic development. People who practice budo seek to avoid conflict and use martial arts only as a last resort. Karate-do, judo, and aikido are forms of budo.

Another martial art that developed in Japan is *ninjutsu (nihn JUHT soo)*, which means *the art of stealing in*, or espionage. People who practice ninjutsu are called *ninja.* Mountain mystics developed ninjutsu in the late 1200's. At that time, ninja were masters at all forms of armed and unarmed combat, including the use of disguises, bombs, and poisons. Although the rulers of Japan banned ninjutsu in the 1600's, the ninja practiced it secretly and preserved its techniques. Ninjutsu gained international interest in the mid-1980's. Today, ninja practice their art not as espionage, but as a traditional martial art with a nonviolent philosophy.

Korean martial arts. The most popular martial art in Korea is *tae kwon do*, or "the art of kicking and punching." Tae kwon do combines the abrupt movements of karate and the circular patterns of kung fu with its own spectacular jumping and spinning kicks. It also employs punching, dodging, and blocking techniques.

The Korean martial arts probably originated during the Great Silla dynasty (A.D. 668-935). In the mid-1900's, several Korean martial arts styles called *kwans* merged to form tae kwon do. In the 1960's, tae kwon do began to spread internationally and now ranks as one of the world's most popular martial arts.

American martial arts. Since 1902, when judo was introduced, the United States has become a melting pot of Asian martial arts and styles. Karate was introduced in 1946 and today has more U.S. practitioners than anywhere else in the world. Some U.S. instructors have broken their ties with Asian traditions and philosophies to form what is known as *American karate.*

Martial arts in other countries. In the 1970's, the art of *escrima (ehs KREE mah)* spread from the Philippines throughout the Western world. It is an art in which barehanded techniques and knife or stick techniques are interchangeable. Also in the 1970's, the arts of *pencak silat*, also spelled *pentjak silat*, developed in Indonesia and Malaysia. They have many empty hand and weapons styles. A Brazilian martial art called *capoeira* began to spread internationally during the 1970's. Capoeira emphasizes lower body movement and also is practiced as a dance and a form of exercise. Paul Crompton

Martial law, *MAHR shuhl*, is a temporary, emergency form of government under military rule. It may be organized in an emergency, such as a natural disaster, a political or economic crisis, or a riot. For example, martial law was declared in the Philippines in 1972 to control groups that opposed the civil government's policies. The new military government restricted the activities of these groups, which included political parties, labor unions, and other organizations. In wartime, a country may declare martial law in its own territory or in enemy territory then in its possession. Under martial law, military laws and the decisions of military institutions are substituted for all civil laws and civil courts. Martial law does not exist if the civil government remains in power but uses military forces to maintain order.

The Constitution of the United States does not specifically provide for martial law. But it implies the power by giving the federal government the right and responsibility to protect a state from invasion or internal violence. During the American Civil War (1861-1865), President Abraham Lincoln put troops in control of parts of the North. Most state constitutions allow the governor to declare martial law within the state. Robert C. Mueller

Martin is the name for several birds in the swallow family. The *purple martin* is the best-known martin in North America. It is about 8 inches (20 centimeters) long. The male is a dark purplish-blue color. The birds migrate to Central and South America in the winter. They have been seen in summer as far north as the Saskatchewan Valley in Canada. Purple martins nest in *colonies* (large groups). They originally built their nests in holes

WORLD BOOK illustration by John Rignall, Linden Artists Ltd.

The martin is a swallow. The male purple martin, *bottom,* is purplish in color. The female purple martin, *top,* is dull gray.

in dead trees, but they now nest primarily in large, multiroomed birdhouses built especially for them. Martins will return to the same birdhouse year after year. The female lays from three to eight white eggs.

Martins help people by eating ants, flies, beetles, mosquitoes, and other winged insect pests. In New England, house sparrows and starlings have driven most of the martins from their homes. Donald F. Bruning

Scientific classification. Martins belong to the swallow family, Hirundinidae. The purple martin is *Progne subis.*

See also **Bird** (picture: Birds' eggs).

Martin V (1368-1431) was elected pope in 1417. His election at the Council of Constance ended the Great Schism that had divided the papacy since 1378 (see **Roman Catholic Church** [The Great Schism]).

Martin labored to restore order to the church. Although he placed many of his relatives in positions of authority, he did attempt to reform some of the worst abuses within the church. Martin also arranged *concordats* (agreements) with Germany, France, Italy, Spain, and England. According to a decree of the Council of Constance, Martin had to call councils regularly. He convened a council at Pavia, Italy, in 1423 and another at Basel, Switzerland, in 1431. Radical reformers eventually took over the Basel council, but Martin died shortly before it met for the first time.

Martin's given and family name was Oddone Colonna. He was born into a famous and powerful family in Rome. Kenneth Pennington

Martin Luther King, Jr., Day is a United States national holiday honoring the birthday of civil rights leader Martin Luther King, Jr. The holiday is observed each year on the third Monday in January. King's actual birthday was Jan. 15, 1929. On Martin Luther King, Jr., Day, most government offices and schools close for the day, but many private businesses remain open.

A campaign to establish a holiday honoring King began soon after he was assassinated in 1968. In 1983, Congress made his birthday a federal holiday, first celebrated on Jan. 20, 1986. Today, the holiday is also observed by all the states. Alton Hornsby, Jr.

Martin Luther King, Jr., National Historic Site, in Atlanta, Georgia, includes the birthplace, church, and burial place of the noted civil rights leader. King was born in Atlanta in 1929 and buried there in 1968 after he was shot and killed by an assassin. King, known for his eloquent speaking ability, was the main leader of the civil rights movement in the United States in the 1950's and 1960's. He won the 1964 Nobel Peace Prize for leading nonviolent civil rights demonstrations.

The historic site includes more than 20 buildings in Atlanta's Sweet Auburn neighborhood. Two blocks from King's childhood home at 501 Auburn Avenue is Ebenezer Baptist Church, where King's grandfather and father were pastor. King served as co-pastor there with his father from 1960 until his death. King's grave is near the church. The historic site was established in 1980.

Critically reviewed by the Martin Luther King, Jr., National Historic Site

Martin of Tours, Saint (316?-397), is the patron saint of France. During his lifetime, he became famous for healing the sick, performing miracles, and founding churches and monasteries.

Martin was born into a pagan family in what is now Szombathely, Hungary, and grew up in Pavia, Italy. At the age of 15, he joined the Roman Army. Three years later, he was baptized a Christian. Martin was discharged from the army about 356 and became a follower of Hilary, the bishop of Poitiers, France. About 360, Hilary helped Martin found the first French monastery, located at Ligugé, near Poitiers. About 371, Martin became bishop of Tours, France.

Martin's friend Sulpicius Severus wrote a biography of the saint that helped to promote monasticism and the reputation of Martin in the West. The biography includes the most famous legend about Martin. It tells that, while a soldier, Martin divided his cloak with a freezing beggar. Later, in a dream, the beggar was revealed to Martin as Jesus Christ. Martin's feast day is November 11. Richard R. Ring

Martini, Simone. See Simone Martini.

Martinique, *MAHR tuh NEEK,* is a French island in the West Indies. The oval-shaped island covers 425 square miles (1,100 square kilometers). Martinique's capital is Fort-de-France. For location, see **West Indies** (map).

Martinique has many volcanic mountains. The highest and most famous of these is Mount Pelée, which rises 4,583 feet (1,397 meters). This volcano suddenly erupted in 1902 and destroyed the city of St.-Pierre. About 38,000 people died. Only one person survived.

Martinique has about 392,000 people. Ninety percent of the people are blacks. Others are of European ancestry, mainly French. Martinique's sunny climate and beautiful scenery help make tourism its most important industry. Its chief crop is sugar cane. Bananas, cotton, pineapples, and tobacco also grow there. Other industries include petroleum refining and rum distilling.

Christopher Columbus reached Martinique in 1502, on his fourth voyage. The French began to colonize the island in 1635. They made Fort-de-France (originally Fort Royal) the capital in 1692. The Empress Josephine, first wife of Napoleon I, was born at Trois-Ilets in Martinique. The French made Martinique an overseas *department* (administrative district) in 1946. In 1958, Martinique chose to remain a department. It is governed by a general council elected by the people. In 1974, the island

also became a region of France. As a region, it has a regional council responsible for social and economic planning. The island sends representatives to the French Parliament. Gerald R. Showalter

See also **Fort-de-France; Mount Pelée.**

Martins, Peter (1946-), is a Danish-born dancer and *choreographer* (dance creator). As a featured performer with the New York City Ballet, he gained fame for his fine classical technique. He was co-ballet master in chief of the New York City Ballet with Jerome Robbins from 1983 until Robbins resigned in 1990. Martins then assumed sole artistic leadership as ballet master in chief.

Martins was born on Oct. 27, 1946, in Copenhagen and received traditional dance training at the Royal Danish Ballet beginning at the age of 8. He joined that company in 1964 and became a solo dancer in 1967. From 1970 to 1983, Martins was a principal dancer for the New York City Ballet. He created many roles in ballets by George Balanchine and Jerome Robbins, notably in partnership with Suzanne Farrell and other leading ballerinas. Selma Landen Odom

Marvel-of-Peru. See **Four-o'clock.**

Marvell, *MAHR vuhl,* **Andrew** (1621-1678), was perhaps the finest of the English Metaphysical poets of the mid-1600's. In addition to the influence of John Donne, Marvell also showed the influence of the English classical poet Ben Jonson. Marvell's verse blends argumentative vigor with classical smoothness and control, a blend that critic and poet T. S. Eliot described as "a tough reasonableness beneath the slight lyric grace." Marvell's best poems are a series of lyrics written about 1650. They include "The Garden" and "To His Coy Mistress." The latter poem includes the famous lines:

> Had we but world enough and time,
> This coyness, lady, were no crime.

and

> But at my back I always hear
> Time's winged chariot hurrying near. ...

It ends grandly:

> Let us roll all our Strength, and all
> Our Sweetness, up into one Ball:
> And tear our Pleasures with rough strife,
> Thorough the Iron gates of Life.
> Thus, though we cannot make our Sun
> Stand still, yet we will make him run.

Marvell was born on March 31, 1621, near Hall in Yorkshire. During the Puritan revolution, he backed Oliver Cromwell and assisted John Milton when Milton was a high government official. Marvell served in Parliament from 1659 to his death. In his later years, he wrote political satire against the king and court. Gary A. Stringer

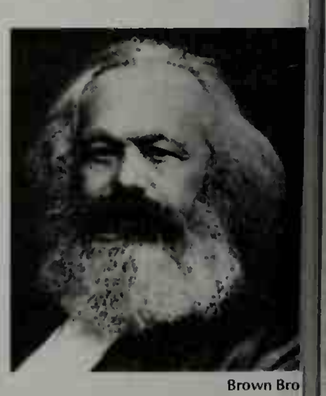
See also **Metaphysical poets.**

Marx, Karl (1818-1883), ranks among the most important thinkers of the 1800's. Few writers in all of history rival him for his broad influence on world affairs. His writings helped form a foundation for the political and economic system known as Communism.

Marx predicted that capitalism would collapse in industrialized countries and that Communism would eventually take its place. He thought capitalism would end with a workers' revolution against the owners of factories and other property used to produce goods and services. In the revolution, the workers would gain control of economic resources and the government.

In the 1900's, Marx's thinking shaped the policies of socialist and Communist governments in many countries. His ideas also influenced numerous academic fields, especially economics, history, and political science, even in capitalist nations.

Marx's life



Childhood. Karl Heinrich Marx was born on May 5, 1818, in the town of Trier, in what is now western Germany. At that time, the region was part of Prussia. Both Marx's father, Heinrich, and his mother, Henrietta, were born into Jewish families. In fact, both of Marx's grandfathers were rabbis. However, Marx's father had converted to Lutheranism about a year before Karl's birth. The conversion probably resulted from the enforcement of anti-Jewish laws by government authorities. But it also helped Marx's father, a lawyer, advance in his career. The children in the family, including Karl, were baptized in 1824, and Marx's mother converted the next year.

University education. In 1835, Marx began studying law at the University of Bonn. The next year, he transferred to the University of Berlin. There, he switched his focus to philosophy. In Berlin, he became known as a critic of religion and of the Prussian government. He earned a doctorate in philosophy at the University of Jena in 1841. But his criticism of religion and the government ended his hopes for a job as a professor. The Prussians and especially Prussia's royal family, who were deeply religious, controlled the jobs at most universities in the German-speaking world.

With an academic career closed to him, Marx turned to journalism, becoming an associate editor of a radical newspaper in Cologne called the *Rheinische Zeitung.* Prussian authorities opposed the paper because it often criticized the Prussian government.

Marriage and move to Paris. In 1843, Marx married Jenny von Westphalen, the daughter of a German baron. Their marriage seemed happy. In times of crisis, Marx relied on his wife for both emotional and financial support. Also in 1843, the Prussian authorities stepped up their efforts against the *Rheinische Zeitung.* As a result, Marx and his wife left Prussia and moved to Paris. At that time, Paris was the home of many intellectuals and rebels from throughout the world. Marx soon became involved in their disputes and causes.

About this time, three key events happened in Marx's life. First, he became involved in a workers' movement that favored socialism as a solution to the problems of the poor. Second, he met and became friends with the German journalist Friedrich Engels. Marx and Engels were both active in the workers' movement, and they formed an intellectual partnership. Third, France became an ally of Prussia, and French authorities

Brown Bro

Karl Marx

cracked down on immigrants who criticized Prussia's government. Because of the crackdown, Marx moved to Brussels, Belgium, in 1845. There, with Engels, he wrote his best-known work, the *Communist Manifesto* (1848).

In 1848, a parliamentary government came to power in Prussia. Marx then briefly returned to Cologne and his old journalism career. He edited another radical newspaper, the *Neue Rheinische Zeitung*. But the Prussian aristocracy soon regained control of the government.

Move to London. In 1849, Marx fled to London. His wife's financial resources became exhausted, and the couple fell into poverty. Engels gave Marx money during this period. Marx also tried to make ends meet by writing as an international correspondent for the *New York Tribune* and other newspapers.

In London in 1864, Marx founded the International Workingmen's Association (later called the First International), which was dedicated to improving the life of the working class. About this time, Marx wrote his most ambitious work, *Das Kapital (Capital)*. He planned to make it a four-volume work but completed only three volumes. Only the first was published during his lifetime, in 1867. Engels edited the second and third volumes after Marx died in 1883. They were published in 1885 and 1894.

Marx's ideas

Early development. As a student, Marx was heavily influenced by the work of the German philosopher G. W. F. Hegel. The young Marx adopted many of Hegel's ideas, including the notion that rational ideas were the driving force in history. In the early 1840's, however, Marx began to move away from a strictly Hegelian philosophy. He rejected Hegel's notion that rational ideas determined events and instead maintained the opposite, that material forces—the forces of nature and especially of human economic production—determined ideas.

In Paris in the 1840's, Marx became interested in the ideas of French socialists, including Pierre J. Proudhon and Charles Fourier. A key issue among Paris intellectuals was the growing number of people who had been impoverished by the Industrial Revolution, a period of rapid industrial growth that had begun in the 1700's.

During the Industrial Revolution, most factory workers and miners in France, Germany, the United Kingdom, and other countries were poorly paid and worked long hours under unhealthful and dangerous conditions. To Marx, older explanations for poverty did not seem to explain these new developments. For example, he rejected the arguments of the French socialists who claimed poverty resulted from the greed of the wealthy. He preferred the more scientific theories of British free-market thinkers, including Adam Smith and, especially, David Ricardo. Ricardo and Smith had argued that changes occur in society due to the automatic and irresistible forces of economic competition.

By the mid-1840's, Marx had adopted the four basic elements of his philosophy: (1) Hegel's idea that history progresses through a necessary series of conflicts; (2) *materialism,* which maintains that the physical world accounts for everything real; (3) socialism and its emphasis on public ownership of property used for economic production; and (4) the capitalist idea that market forces determine economic activity.

The ***Communist Manifesto,*** Marx's most famous work, outlined what became known as Marxism. According to the *Manifesto,* which was published in 1848, industrial Europe and North America soon would experience economic and social collapse due to the unavoidable defects of capitalism. In the collapse, the working class would use socialism to dismantle capitalism's foundation of private property. The *Manifesto* invited industrial workers to join the International Workingmen's Association, which called itself "communist." The *Manifesto* also distinguished the working class from other groups, including middle-class business owners.

In 1848, revolutions occurred throughout Europe. But instead of being led by workers, many of them were nationalist, middle class, or even democratic in character. Nevertheless, they provided numerous readers for the *Manifesto*. As a result, Marx's ideas quickly spread.

Das Kapital later offered a theoretical explanation of how capitalism developed and how it would be transformed into Communism. In this work, Marx traced the origin of capitalism to the establishment of private *productive property*—that is, property used to produce goods and services. The owners of this property possessed and enjoyed more goods and services than they produced by their own labor. By contrast, the working class produced more goods and services than they would ever own or enjoy. In *Das Kapital,* Marx argued that this division of classes created a conflict that drove civilization through various stages of history.

Marx thought that all civilizations throughout history had inevitably experienced class conflict between workers and the owners of productive property. In ancient societies, according to Marx, these two classes were the masters and the slaves. In the Middle Ages, they were the lords and the vassals. In the industrial, capitalist world, they were the middle-class owners of productive property and the workers. Marx called the middle-class owners the *bourgeoisie* (pronounced *boor zhwah ZEE)* and the workers who did the actual labor the *proletariat*.

Unlike many other social critics during the Industrial Revolution, Marx did not see capitalism as a moral problem. For example, the English novelist Charles Dickens and the French writer Victor Hugo saw child labor, extremes of wealth and poverty, and other aspects of capitalism as immoral. Marx, however, saw capitalism as a necessary stage in resolving workers' problems. He thought that under capitalism, those problems took their purest form and thus would result in a workers' revolution that would lead to Communism.

Marx believed that the boom-and-bust business cycles of capitalism would help trigger the revolution. According to him, occasional overproduction created more goods and services than owners could sell. Forced by competition to be efficient, owners had to either fire workers or slide into the ranks of the proletariat themselves. But with fewer workers receiving wages, fewer people could buy products. As a result, the problem of overproduction became more serious. According to Marx, this spiraling process would eventually result in a swelling of the working class and a shrinking of the owner class until the system broke down.

The working class would then revolt and seize control of the government. A workers' dictatorship would use the government to end private ownership of productive property. Eventually, social classes would disappear.

Even government, no longer needed to enforce public ownership of property, would "wither away." A true Communist society would then have been achieved.

Marx's influence

Marx's thinking had its greatest impact among Communists. The government and economy of the Soviet Union, the world's most powerful Communist country, was based on Marxist doctrines as uniquely interpreted by V. I. Lenin. The Soviet Union was formed in 1922, and Lenin became its first dictator. The official principles of the Soviet Union and many other Communist nations became known as Marxism-Leninism. Other Communist countries included the nations of Eastern Europe—most of which the Soviet Union controlled—as well as China, Cuba, North Korea, and Vietnam.

Marx's thinking also influenced non-Communist socialists. But many of them disagreed with him on certain points. For example, many moderate socialists rejected his idea that socialism had to be achieved by a revolution. They believed instead that socialism could be established gradually by working within democratic institutions and by forming an alliance with the middle class.

In 1991, the Soviet Union broke apart into a number of separate countries. About the same time, many Eastern European countries adopted non-Communist governments. Also in the late 1900's, China and other Communist nations introduced capitalist elements into their economies. Many people saw these events as proof that Marx's predictions had been wrong.

However, many of Marx's admirers argue that the policies of Communist governments have had little in common with Marx's thinking. For example, they point to Marx's claim that government would wither away. In the Soviet Union and other Communist countries, the government showed no signs that it would ever do so.

Also, in spite of the decline of Marx's influence on government, his ideas still affect notions of social conflict, historical development, and class throughout the world. In addition, much of today's criticism of capitalism and free-market theories still reflects the impact of Marx's writings. Stephen Schneck

Marx brothers were three American brothers who became famous for their zany antics in motion pictures. The brothers were Groucho (Julius, 1890-1977), Chico (Leonard, 1887-1961), and Harpo (Adolph, later changed to Arthur, 1888-1964). Groucho became known for his insults, long cigar, and bushy mustache and eyebrows. Chico spoke in an Italian accent and played the piano. Harpo, who never spoke in the films, played the harp. A fourth brother, Zeppo (Herbert), played romantic roles in their films until he left the team in the mid-1930's. A fifth brother, Gummo (Milton), appeared on the stage but made no movies.

The Marx brothers as a team made 13 movies, many of which ridiculed parts of society. The brothers' first two films, *The Cocoanuts* (1929) and *Animal Crackers* (1930), were based on Broadway shows in which they had starred. Their other movies include *Monkey Business* (1931), *Horse Feathers* (1932), *Duck Soup* (1933), *A Night at the Opera* (1935), and *A Day at the Races* (1937).

United Press Int.

The Marx brothers starred in *Horse Feathers,* a zany 1932 motion-picture comedy. They were Chico, *left,* holding an apple; Groucho, smoking the cigar; and Harpo, *far right.*

The Marx brothers were born in New York City and began their career when they were children. With two other brothers, they starred in vaudeville and several Broadway shows before making movies. From 1950 to 1961, Groucho was the host of a popular television quiz show called "You Bet Your Life." Roger Ebert

Marxism. See Marx, Karl.

Mary was the mother of Jesus. She is also known as the Virgin Mary, the Blessed Virgin Mary, or the Blessed Virgin. According to the Gospels of Luke and Matthew, Mary gave birth to Jesus in Bethlehem. According to Luke, her family lived in Nazareth, and she had gone to Bethlehem with Joseph to have their names recorded as members of the House of David.

The sufferings of Jesus brought great sorrow into Mary's life. At the Crucifixion, according to John 19, Jesus asked His beloved disciple, perhaps John, to take care of her. Little is known about her later life. It is believed that she died in Jerusalem about A.D. 63. Mary is venerated by the Roman Catholic, Anglican, and Eastern Orthodox churches as the "Mother of God."

The story of Mary has always been a favorite subject of artists and musicians. Many great paintings and songs have been based on the incidents and traditions of her life. J. H. Charlesworth

Mary I (1516-1558) was queen of England from 1553 until her death in 1558. She was the daughter of King

Henry VIII and Catherine of Aragon. Mary became queen after her half brother, King Edward VI, died. An attempt to set her aside in favor of her cousin Lady Jane Grey, "the nine-day queen," failed. The English people preferred Mary because they considered her the rightful heir. See **Grey, Lady Jane; Tudor, House of.**

National Portrait Gallery, London

Mary I of England

Mary was a devout Roman Catholic and tried to bring England back to the Roman Catholic Church. She repealed a law that had made Protestantism the state religion. Mary also reestablished certain severe laws against heresy or disbelief in Roman Catholic doctrine.

Mary became known as "Bloody Mary" because of the persecutions she caused. More than 300 people were burned at the stake during her reign. Among them were Thomas Cranmer, Nicholas Ridley, and Hugh Latimer, all high-ranking Protestant clergymen (see **Cranmer, Thomas; Latimer, Hugh; Ridley, Nicholas**). Mary also drove many Protestant clergymen into exile.

Mary married King Philip II of Spain. Their marriage was unpopular because many English people viewed Spain as England's greatest enemy. Philip persuaded Mary to join Spain in a war against France. But France won the war, which officially ended in 1559, after Mary's death. Mary died childless and was succeeded by her Protestant half sister, Elizabeth (see **Elizabeth I**).

Mary II (1662-1694) was the queen of England from 1689 to 1694. She ruled jointly with her husband, King William III. Mary devoted much of her time to religious and charitable projects. She helped found the College of William and Mary in Virginia in 1693. Mary was born in London. She was the daughter of King James II. Although her father was a Roman Catholic, Mary was raised a Protestant. In 1677, she married William of Orange, the Protestant ruler of the Netherlands. In the Glorious Revolution of 1688, William's forces invaded England and forced James to flee the country. William and Mary became the rulers of England in 1689.

Roger Howell, Jr.

See also **William III.**

Mary, Queen of Scots (1542-1587), was the only surviving child of King James V of Scotland. The princess, whose mother was Mary of Guise, was only a week old when James V died. However, she was immediately proclaimed queen of Scotland.

Mary was sent to France at the age of 5 to be educated. She married the French *dauphin* (crown prince) at the age of 15. The dauphin became king of France soon after their marriage, but he died in 1560.

Her reign. Mary returned to Scotland in 1561, soon after it had officially become a Protestant country. Before the 1560's, the Roman Catholic Church had been Scotland's official church. Although Mary was a Catholic, she did not oppose the spread of the Protestant faith at first. But in 1565, she married her cousin Henry Stuart, who was also known as Lord Darnley. This young Catholic nobleman's rise to power caused leading Protestant lords to revolt. The rebellion was quickly put down. But the queen soon discovered that she had married an ineffective and overly ambitious husband, and she came to hate him.

A rumor began to develop that Mary was having an affair with her private secretary, an Italian musician named David Riccio (also spelled Rizzio). A band of Protestant nobles dragged Riccio from Mary's presence and stabbed him to death in March 1566. Darnley, Mary's husband, was one of the leaders in the murder, but Mary fled with him to Dunbar and thus preserved her power. Mary gave birth to a son three months later. This son eventually became King James I of England (see **James (I)**).

Mary still hated her husband. Before long she began to show marked attention to James Hepburn, Earl of Bothwell (see **Bothwell, Earl of**). Early in 1567, Bothwell murdered Darnley. Mary married Bothwell three months later.

Her death. This marriage was Mary's fatal mistake. She was forced to abdicate in favor of her son in June 1567 and was imprisoned. She escaped in 1568 and raised a small army, but most people in Scotland opposed her. Her forces were defeated, and she fled to England.

Red and black chalk drawing (about 1561) by François Clouet; Bibliothèque Nationale de France, Paris

Mary, Queen of Scots

Mary was next in line for the English throne after her second cousin Queen Elizabeth I. But Mary refused to recognize Elizabeth as queen. Beginning in 1569, Mary supported a series of plots to overthrow her (see **Elizabeth I**).

Elizabeth kept Mary confined and for years refused demands for her execution. But eventually Elizabeth had her tried for high treason. Mary was found guilty, and Elizabeth reluctantly signed Mary's death warrant. Mary was beheaded on Feb. 8, 1587. Richard L. Greaves

Tilghman Island in Chesapeake Bay provides a natural harbor for pleasure boats. The bay divides Maryland into two parts, called the Eastern Shore and the Western Shore. The state's long Chesapeake Bay shoreline offers opportunities for recreational boating, fishing, and swimming.

Maryland *The Old Line State*

Maryland is an important industrial and shipping state of the United States. It lies in the northeastern corner of the Southern States. Chesapeake Bay, which cuts deep into Maryland, provides the state with several excellent harbors. Historic Baltimore, the state's largest city, is one of the world's greatest port cities. Annapolis, home of the U.S. Naval Academy, is the capital of Maryland.

Chesapeake Bay divides Maryland into two parts. The part of Maryland east of the bay is called the Eastern Shore. The part west of the bay is the Western Shore. The two parts join north of the bay in the northeastern corner of the state. The Eastern Shore shares the Delmarva Peninsula with parts of Delaware and Virginia. The Eastern Shore and part of the Western Shore are low and relatively flat. But western Maryland has rolling plains, hills and valleys, mountains, and plateaus. Most parts of Maryland have good farmland. Forests cover more than 40 percent of the state.

Service industries, such as government and trade, play a leading role in Maryland's economy. The state's chief manufactured products include computer and electronic products, processed foods, and chemicals. Manufacturing in Maryland is centered in the Baltimore area and in the Maryland suburbs of Washington, D.C.

Many farms on the Eastern Shore raise chickens.

The contributors of this article are Robert D. Mitchell, Professor of Geography at the University of Maryland, and Edward C. Papenfuse, State Archivist, Maryland State Archives.

Many dairy farms lie in the river valleys of the Western Shore. Greenhouse and nursery products are important in the larger cities. Maryland is an important producer of clams, crabs, and oysters.

Maryland was named for Queen Henrietta Maria, the wife of King Charles I of England. In 1632, Charles granted the Maryland region to Cecilius Calvert, the second Lord Baltimore. Calvert, a Roman Catholic, believed in religious freedom and welcomed settlers of all faiths to Maryland. Calvert and his descendants—the Lords Baltimore—ruled Maryland during most of the period when it was an English colony. During the Revolutionary War in America (1775-1783), the Second Continental Congress met for about three months in Baltimore. After the war, the Congress of the Confederation met for several months in the Maryland State House in Annapolis. In 1791, Maryland gave part of its land to the federal government for the District of Columbia (or Washington, D.C.), the new national capital.

Francis Scott Key wrote "The Star-Spangled Banner" while watching the British bombard Baltimore's Fort McHenry during the War of 1812. Maryland, though a Southern state, remained loyal to the Union during the American Civil War. Several Civil War battles were fought in Maryland, including the Battle of Antietam—one of the bloodiest of the war.

Maryland is nicknamed the *Old Line State* after its heroic "troops of the line." These troops won praise from George Washington, who was commander in chief of the Continental Army during the Revolutionary War.

Interesting facts about Maryland

WORLD BOOK illustrations by Kevin Chadwick

The largest white oak tree in the United States is the Wye Oak in Wye Mills. This tree is 107 feet (33 meters) tall, and has a circumference of 34 $\frac{1}{2}$ feet (10.5 meters) at the base of the trunk. It is more than 400 years old.

The first umbrella factory in the United States was established in Baltimore in 1828. The slogan "Born in Baltimore—raised everywhere" came to describe the umbrellas made there.

First umbrella factory

The first elevated electric railway in the United States was built in Baltimore in 1893.

Jousting is the official state sport of Maryland. Visitors may watch a form of Old English jousting in which galloping riders try to catch small rings on a spear. Several tournaments are held during the year.

The Baltimore Department of Health is the oldest continuously operating municipal health department in the United States. It was organized in 1793 to help prevent the spreading of diseases.

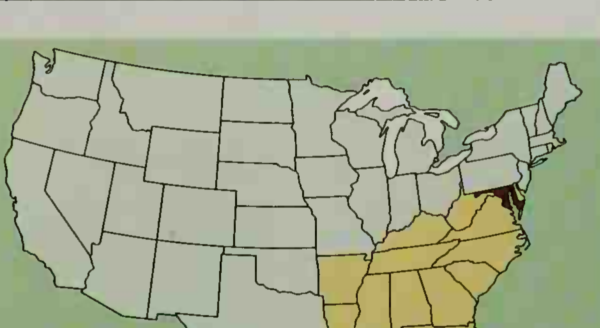
Maryland in brief

Symbols of Maryland



The state flag, adopted in 1904, bears the coats of arms of two families related to Lord Baltimore—the Calverts and the Crosslands. The black-and-gold quarters are the Calverts' arms. The red-and-white quarters represent the Crosslands. The state seal was adopted in 1876. The front shows Lord Baltimore as a knight. On the back, the farmer symbolizes Maryland. The fisherman represents Lord Baltimore's Newfoundland colony.

State flag

State seal

Maryland (brown) ranks 42nd in size among all the states, and 13th in size among the Southern States (yellow).

The State Capitol is in Annapolis, Maryland's capital since 1694. St. Marys City (now St. Mary's City) was the capital from 1634 to 1694.

General information

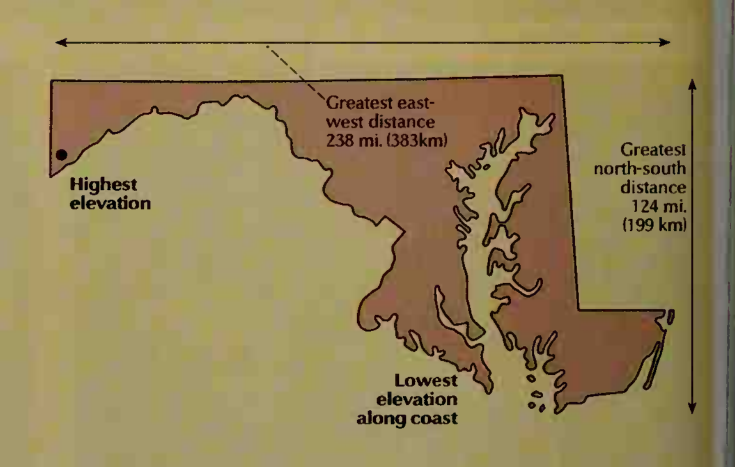
Statehood: April 28, 1788, the seventh state.
State abbreviations: Md. (traditional); MD (postal).
State motto: *Fatti Maschii Parole Femine* (Manly Deeds, Womanly Words), Italian motto of the Calvert family.
State song: "Maryland, My Maryland," sung to the music of "O, Tannenbaum." Words by James Ryder Randall.

Land and climate

Area: 10,455 sq. mi. (27,077 km^2), including 680 sq. mi. (1,761 km^2) of inland water but excluding 1,842 sq. mi. (4,771 km^2) of coastal water.

Elevation: *Highest*—Backbone Mountain, 3,360 ft. (1,024 m) above sea level. *Lowest*—sea level along the coast.

Coastline: 31 mi. (49 km); including Chesapeake Bay, Potomac River, and other rivers, 3,190 mi. (5,134 km).



Record high temperature: 109 °F (43 °C) in Allegany County on July 3, 1898, and at Cumberland and Frederick on July 10, 1936.

Record low temperature: −40 °F (−40 °C) at Oakland on Jan. 13, 1912.

Average July temperature: 75 °F (24 °C).

Average January temperature: 33 °F (1 °C).

Average yearly precipitation: 43 in. (109 cm).

The state's official Web site at www.mec.state.md.us also provides a gateway to much information on Maryland's economy, government, and history.

1791 Maryland gave land for the District of Columbia.
1828 Construction of the Baltimore and Ohio Railroad began.
1864 Maryland adopted a constitution abolishing slavery.
1919-1933 Maryland resisted the nation's prohibition laws and became known as the Free State.
1985 Maryland, with the cooperation of nearby states, began a cleanup of pollution in Chesapeake Bay.

Population. The 2000 United States census reported that Maryland had 5,296,486 people. The population had increased 11 percent over the 1990 figure, 4,781,468. According to the 2000 census, Maryland ranks 19th in population among the 50 states.

About 93 percent of the people in Maryland live in one of the state's five metropolitan areas (see **Metropolitan area**). These include the Baltimore, Cumberland, and Hagerstown metropolitan areas, and the Maryland portions of the Washington, D.C., and Wilmington, Delaware, metropolitan areas. For the populations of these areas, see the *Index* to the political map of Maryland.

Baltimore is the state's largest city. Other large population centers, in order of population, are Columbia, Silver Spring, Dundalk, and Wheaton-Glenmont.

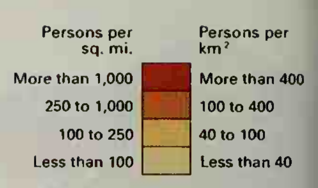
Maryland is one of the most densely populated states. Only New Jersey, Rhode Island, Massachusetts, and Connecticut rank higher in terms of population density.

About a fourth of Maryland's people are African Americans. Other large population groups in Maryland include people of German, Irish, English, Italian, Polish, and American Indian descent. Hispanics and Asians each account for 4 percent of Maryland's population.

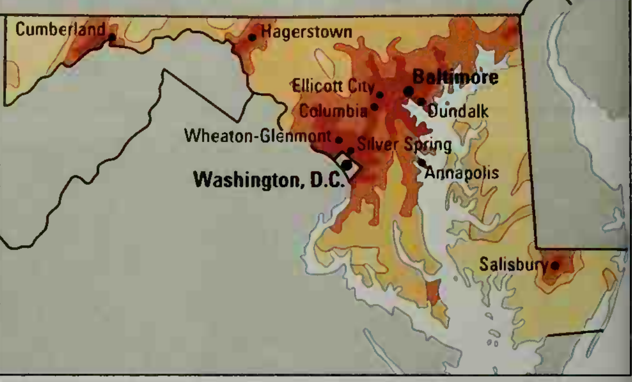
Schools. Church leaders and private tutors taught children in colonial Maryland. Only the children of wealthy families received schooling. The colony first provided funds for public education in 1694. King William's School in Annapolis was the colony's first free school. It was founded in 1696 and became St. John's College in 1784. In 1826, Maryland provided for the establishment of public schools throughout the state. The State Board of Education was established in 1870.

Today, the State Board of Education, appointed by the governor, sets policy for the public schools. The board appoints the state superintendent of schools to carry out its policies. A state law requires children to attend school from ages 5 through 15. For the number of students and teachers in Maryland, see **Education** (table).

Libraries. In 1699, Thomas Bray, an Episcopal minister, set up 30 *parish* (church district) libraries in the colony, with a central library in Annapolis. These were Maryland's first libraries and probably the first in the colonies to loan books. In 1886, Enoch Pratt, a Baltimore iron merchant, established the Enoch Pratt Free Library of Baltimore, one of the oldest public library systems in the United States.



The Johns Hopkins University library in Baltimore has a large collection of medical history materials. The Maryland Historical Society in Baltimore, founded in 1844, and the Maryland State Archives in Annapolis, founded in 1935, have outstanding collections of books and documents dealing with the state's history. The National Agricultural Library in Beltsville has a huge collection of material on farming. The Maryland State Law Library, in Annapolis, has many rare books, maps, and newspapers.



Museums. The Peale Museum, also called the Municipal Museum of the City of Baltimore, is one of the oldest museums in the United States. It opened in 1814 as the Baltimore Museum and Gallery of the Fine Arts. Rembrandt Peale, the founder of the museum, was the son of the famous painter Charles Willson Peale. The museum has many works of the Peale family.

The Baltimore Museum of Art has paintings, prints,

Population density

Most of the people of Maryland live in the Baltimore or Washington, D.C., metropolitan areas. Relatively few people live on the Eastern Shore or in southern Maryland.

WORLD BOOK map; based on U.S. Census Bureau data.

and sculpture. The museum owns a famous collection of paintings by the French artist Henri Matisse.

The Maryland Historical Society in Baltimore owns the original manuscript of "The Star-Spangled Banner." The society's collections include paintings, furniture, silver, quilts, and military uniforms.

The Maryland Science Center in Baltimore features hands-on exhibits dealing with science and nature. Other important museums include the Walters Art Gallery in Baltimore and the U.S. Naval Academy Museum and the Maryland State Archives Museum in Annapolis.

Universities and colleges

This table lists the universities and colleges in Maryland that grant bachelor's or advanced degrees and are accredited by the Middle States Association of Colleges and Schools.

Name	Mailing address
Baltimore, University of	Baltimore
Baltimore Hebrew University	Baltimore
Baltimore International College	Baltimore
Bowie State University	Bowie
Capitol College	Laurel
Columbia Union College	Takoma Park
Coppin State College	Baltimore
Frostburg State University	Frostburg

Visitor's guide

Maryland's long Chesapeake Bay shoreline offers opportunities for boating, fishing, and swimming. Visitors can hunt game birds and animals in the fields and forests, and along rivers. Old mansions and historic sites throughout the state appeal to sightseers. Visitors can still watch a form of old English jousting, in which galloping riders try to catch small rings on a spear. Tournaments are held throughout the year, including a major competition in Calvert County in August.

One of Maryland's most famous annual events is the Preakness Stakes, a horse race run each May at the Pimlico race track in Baltimore. The Preakness, the Kentucky Derby, and the Belmont Stakes make up the famous Triple Crown of horse racing in the United States.

Colonial reconstruction in historic St. Mary's City, near Lexington Park

Places to visit

Assateague State Park and National Seashore, near Ocean City, is most widely recognized for its population of small wild ponies. One legend claims that the horses are descended from the survivors of a Spanish shipwreck.

Chesapeake Bay Maritime Museum, in St. Michaels, features a lighthouse, a saltwater aquarium, and a waterfowl exhibit. The museum also has a floating collection of Chesapeake Bay ships and boats.

Frederick National Historic District, in Frederick, covers about 50 blocks and includes the National Museum of Civil War Medicine, the Barbara Fritchie House and Museum, the Community Bridge, the famous church spires of Frederick, and plenty of shops and restaurants.

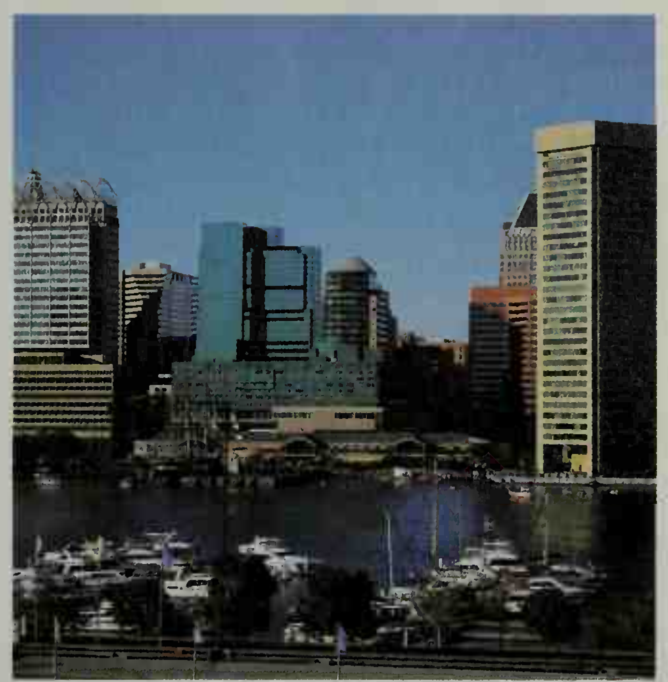
Inner Harbor area of Baltimore includes a number of attractions. *Harborplace and the Gallery* is an enclosed complex of shops and restaurants. *Maryland Science Center* features a science museum, a planetarium, and a special IMAX theater presentation. *National Aquarium in Baltimore* has thousands of fish, reptiles, and birds.

St. Mary's City, a village near Lexington Park, became Maryland's first colonial settlement in 1634. A copy of the first Maryland statehouse stands in the historic village. Other attractions include a replica of the *Dove,* Lord Baltimore's ship; a reconstruction of a tobacco plantation; a natural history museum; and a reconstructed inn of the 1600's.

National monuments and historic sites. Antietam National Battlefield, near Sharpsburg, was the site of one of the bloodiest Civil War battles. On Sept. 17, 1862, Union forces at Antietam turned back the first Confederate invasion of the North. Fort McHenry National Monument and Historic Shrine in Baltimore honors the defense of Baltimore against the British during the War of 1812. During that defense, on Sept. 13 and 14, 1814, Francis Scott Key was inspired to write "The Star-Spangled Banner."

Other historic sites in Maryland include the Maryland State House and the United States Naval Academy, both in Annapolis. Chesapeake and Ohio Canal National Historic Park extends from Cumberland to Washington, D.C.

State parks and forests. Maryland has 38 state parks and 6 state forests. For information on the state parks of Maryland, write to Director, State Forest and Park Service, Tawes Building, 580 Taylor Avenue, Annapolis, MD 21401.



Annual events

January-March
FMJS East Coast Jazz Festival in Rockville (February); Winterfest in McHenry (March); Maryland Days in St. Mary's City (weekend nearest March 25).

April-June
Ward World Championship Wildfowl Carving Competition in Ocean City (April); Department of Defense Joint Services Open House at the Andrews Air Force Base (May); Preakness Celebration in Baltimore (May); Bay Country Music Festival in Centreville (June); Flag Day Ceremonies at Fort McHenry in Baltimore (June).

July-September
Artscape in Baltimore (July); Rocky Gap Music Festival in Cumberland (August); National Hard Crab Derby in Crisfield (Labor Day weekend); Maryland Seafood Festival near Annapolis (September); Maryland Wine Festival in Westminster (September).

October-December
Autumn Glory Festival in Garrett County (October); Fair Hill International Festival in the Country in Fair Hill (October); Waterfowl Festival in Easton (November); Maryland Christmas Show in Frederick (November-December).

Land regions. Chesapeake Bay divides most of Maryland into two sections. The area east of Chesapeake Bay is called the Eastern Shore. The area west of the bay is called the Western Shore. Maryland has five main land regions. They are, from east to west: (1) the Atlantic Coastal Plain, (2) the Piedmont, (3) the Blue Ridge, (4) the Appalachian Ridge and Valley, and (5) the Appalachian Plateau.

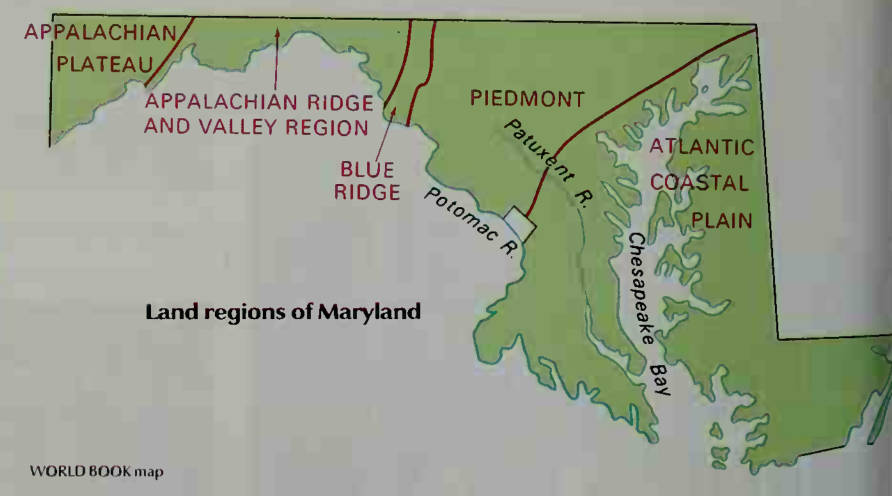
The Atlantic Coastal Plain stretches along the east coast of the United States from New Jersey to southern Florida. In Maryland, the coastal plain covers the entire Eastern Shore and part of the Western Shore. The plain touches a narrow tip of northeastern Maryland. It extends across southern Maryland from the southeastern corner of the state almost to Washington, D.C. The Atlantic Coastal Plain has little elevation on the Eastern Shore, but it rises to about 400 feet (120 meters) on the Western Shore.

The Eastern Shore has some marshy areas. The Pocomoke Swamp, which is 2 miles (3 kilometers) wide, extends from Pocomoke Sound to the Delaware border. The part of the Western Shore south of Baltimore is called Southern Maryland. Tobacco has been raised in Southern Maryland since colonial times.

The Piedmont extends from New Jersey to Alabama. In Maryland, the Piedmont is about 50 miles (80 kilometers) wide. It stretches from the northeastern to the central part of the state. Low, rolling hills and fertile valleys cover the region. The Piedmont rises to about 880 feet (268 meters) at Parrs Ridge, and to about 1,200 feet (366 meters) at Dug Hill Ridge on the Pennsylvania border. Both of these ridges run in a southwesterly direction. They form the divide between streams flowing westward into the Potomac River and those flowing eastward into Chesapeake Bay. Frederick Valley, which lies along the Monocacy River, is a rich dairy-farming area.

The Blue Ridge region extends from southern Pennsylvania to northern Georgia. In Maryland, the region is a narrow, mountainous strip of land between the Piedmont and the Appalachian Ridge and Valley region. South Mountain and Catoctin Mountain form most of the Blue Ridge. Nearly all the region is over 1,000 feet (300 meters) above sea level. It rises to a height of over 2,000 feet (610 meters) near the Pennsylvania border. The Blue Ridge region was named for the blue haze that sometimes hangs over its forest-covered ridges.

The Appalachian Ridge and Valley is a land region that stretches southwestward from New Jersey to Alabama. The Maryland portion is a strip of land that separates Pennsylvania from West Virginia. At Hancock, Maryland measures less than 2 miles (3 kilometers) from its northern to its southern borders.



The Great Valley, known in Maryland as Hagerstown Valley, covers the eastern portion of the state's ridge and valley region. Much of this fertile valley is filled with orchards and farms. West of the valley, a series of ridges crosses the state from northeast to southwest. Some of the ridges rise to almost 2,000 feet (610 meters). Forests cover about two-thirds of the region.

The Appalachian Plateau extends from New York to Georgia. It covers a triangle-shaped area in the extreme western part of Maryland. The Allegheny Mountains cover most of the region. They make up part of the huge Appalachian Range. Backbone Mountain, in the northwest, is the highest point in Maryland. It rises 3,360 feet (1,024 meters). Streams have cut deep valleys into the

Appalachian Plateau. The valleys served as early trails to the West. Forests cover nearly three-fourths of the area.

Coastline of Maryland measures only 31 miles (49 kilometers) along the Atlantic Ocean. But the many arms and inlets of Chesapeake Bay give Maryland a total coastline of 3,190 miles (5,134 kilometers). These arms and inlets provide excellent harbors. Islands in Chesapeake Bay include Bloodsworth, Deal, Hooper, Kent, Smith, South Marsh, Taylors, and Tilghman.

Rivers and lakes. Most of Maryland is drained by rivers that flow into Chesapeake Bay. Seven large rivers cross the Eastern Shore area. They are the Chester, Choptank, Elk, Nanticoke, Pocomoke, Sassafras, and Wicomico. The Susquehanna River flows into the state from Pennsylvania and empties into Chesapeake Bay. The Gunpowder, Patapsco, and Patuxent rivers all drain the Western Shore and flow into the bay.

The Potomac River forms Maryland's southern and southwestern boundary. South of Washington, D.C., it widens into an arm of Chesapeake Bay. Tributaries of the Potomac drain much of western Maryland.

All Maryland lakes are artificially created. The largest, Deep Creek Lake in the Allegheny Mountains, covers about 4,000 acres (1,600 hectares). It was formed by a dam built across a small tributary of the Youghiogheny River. The dam provides hydroelectric power.

Plant and animal life. Forests cover more than 40 percent of Maryland's land area. The state has over 150 kinds of trees. Oaks are the most common. Others include the ash, beech, hickory, maple, and tupelo.

The black-eyed Susan, Maryland's state flower, grows on the Western Shore. The Western Shore also has many kinds of berries, including blackberries, dewberries, raspberries, and wild strawberries. Grasses and grasslike plants called *sedges* grow on the Eastern Shore. Azaleas, laurel, and rhododendrons grow along the edges of the woods.

Maryland's animal life includes eastern cottontail rabbits, minks, opossums, raccoons, red and gray foxes, and white-tailed deer. The north-central part of the state has chipmunks, otters, squirrels, and woodchucks. Hunters find grouse, partridge, wild turkeys, and woodcocks in western Maryland, and wild ducks and geese along the coastal plain. The Eastern Shore lies along the Atlantic Flyway, a route heavily traveled by migrating geese and ducks. Songbirds are plentiful.

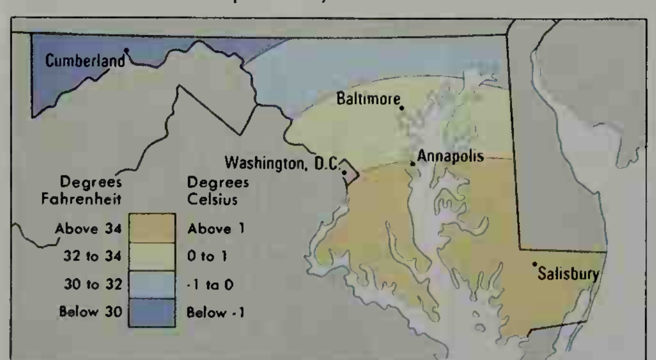
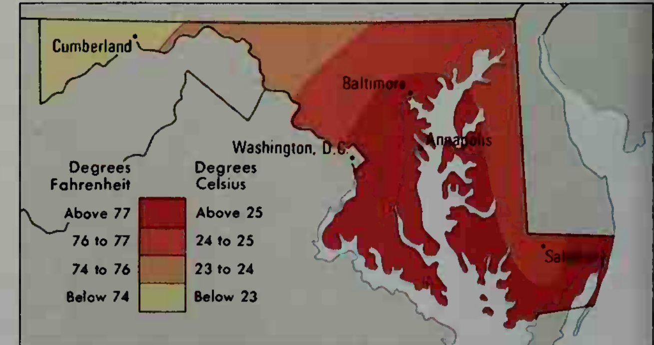
Maryland's coastal waters have great quantities of bluefish, crabs, diamondback terrapins, menhaden, oysters, sea trout, shrimps, and striped bass (called *rockfish* or *rock* in Maryland). Each spring, croakers, alewives, and other fishes swim up Chesapeake Bay to lay their eggs in the larger rivers. Trout live in the cold rivers and streams of northern and western Maryland. Carp, catfish, and suckers are found in the waters of the Piedmont and the coastal plain.



Average yearly precipitation

Maryland has a humid climate. Rain falls fairly evenly throughout the state. Snowfall ranges from light amounts in the southeast to heavy accumulations in the northwest.



Average January temperatures

Maryland has mild winters. Temperatures in the mountainous regions of the northwest are lower than those along the Atlantic coast and in the Chesapeake Bay sections.

Average July temperatures

Maryland's summers are generally very warm. There is little variation in temperature throughout much of the state. The area around the Chesapeake Bay has the highest temperatures.

WORLD BOOK maps

Climate. Maryland has a humid climate, with hot summers and generally mild winters. Temperatures in the mountainous northwest are lower than those along the Atlantic coast and in the Chesapeake Bay region. January temperatures average 29 °F (−2 °C) in the northwest, and 39 °F (4 °C) along the Atlantic coast. Average July temperatures range from 68 °F (20 °C) in the northwest to about 75 °F (24 °C) in the Chesapeake Bay region. The record high temperature, 109 °F (43 °C), occurred in Allegany County on July 3, 1898, and at Cumberland and Frederick on July 10, 1936. Oakland had the lowest temperature, −40 °F (−40 °C), on Jan. 13, 1912.

Maryland's *precipitation* (rain, melted snow, and other forms of moisture) averages about 43 inches (109 centimeters) a year. Rain falls fairly evenly throughout the state. Snow ranges from about 9 inches (23 centimeters) a year in the southeast to about 78 inches (198 centimeters) in the Appalachian Plateau.

Economy

Maryland's economy is based largely on service industries. These industries, taken together, account for the largest part of Maryland's *gross state product*—the total value of all goods and services produced in a state in a year. Because Maryland adjoins Washington, D.C., the U.S. government plays a major role in the state's economy. Many federal offices are in Maryland. Many businesses in this region provide support services to federal agencies. The Baltimore area is Maryland's other major economic center. It is one of the East Coast's leading areas for finance, manufacturing, and trade. Many high-technology companies operate in Maryland.

Natural resources of Maryland include fertile soils and some building materials. Light, sandy loams and stiff, clay soils cover much of the Eastern Shore. The Western Shore south of Baltimore also has loam and clay soils. North-central Maryland has fertile limestone soils. The valleys of western Maryland have a thin covering of soil. Sand and gravel deposits are found in many counties on the Western Shore. Other mined products include clays, coal, limestone, and natural gas.

Service industries account for the largest portion of the gross state product of Maryland.

Community, business, and personal services forms the leading service industry in the state in terms of the gross state product. The most important activities in this industry are private health care and support services for business and government. Private health care consists chiefly of doctors offices and private hospitals. Support services include computer programming, consulting, data processing, janitorial help, and security.

Finance, insurance, and real estate ranks second among Maryland's service industries. Baltimore is one of the leading financial centers in the eastern United States. Several major banking companies and holding companies are headquartered in the Baltimore area.

Government is Maryland's third-ranking service industry in terms of the gross state product. Government services include the operation of public schools and hospitals, and military activities. Federal government agencies in Maryland include the National Institutes of Health and the Census Bureau. Military facilities include several bases, the Bethesda Naval Medical Center, Goddard Space Flight Center, and the U.S. Naval Academy. Most state government offices are in Annapolis and Baltimore.

Wholesale and retail trade ranks fourth among Maryland service industries. The port of Baltimore is a center of wholesale trade. Imported and exported motor vehicles and machinery, and exported chemicals, make up much of the volume of products handled by the port. The leading types of retail trade establishments are automobile dealerships, grocery stores, and restaurants.

Transportation, communication, and utilities rank fifth among Maryland service industries in terms of the gross state product. Many shipping and trucking firms operate in the Baltimore area. Telephone companies are the most important part of the communications industry. Baltimore Gas & Electric is the state's largest utility company. More information about transportation and communication appears later in this section.

Manufacturing. Goods made in Maryland have a *value added by manufacture* of about $19 billion a year. Value added by manufacture represents the increase in value of raw materials after they become finished products. Most of Maryland's manufacturing activity takes place within the Baltimore area and the urban areas near Washington, D.C.

Computer and electronic products are Maryland's leading type of manufactured product in terms of value added by manufacture. Communications equipment and surveillance and navigation instruments rank among the state's most valuable electronic products. Lockheed Martin, a leading maker of aerospace and defense systems, is headquartered in Bethesda.

Food products rank second among Maryland's manufactured products. Maryland's major types of processed foods are soft drinks, alcoholic beverages, spices, and bread. McCormick and Company, Inc., one of the na-

Production and workers by economic activities

Economic activities	Percent of GSP* produced	Employed workers: Number of people	Employed workers: Percent of total
Community, business, & personal services	24	1,035,200	35
Finance, insurance, & real estate	21	249,300	9
Government	18	508,900	17
Wholesale & retail trade	15	620,800	21
Manufacturing	8	187,600	6

Agriculture	1	49,500	2
Mining	†	2,700	†
Total	100	2,971,600	100

*GSP = gross state product, the total value of goods and services produced in a year.
†Less than one-half of one percent.
Figures are for 1998.
Sources: *World Book* estimates based on data from U.S. Bureau of Economic Analysis and U.S. Bureau of Labor Statistics.

tion's largest spice makers, is based near Cockeysville, north of Baltimore.

Chemicals are Maryland's third-leading type of manufactured product in terms of value added by manufacture. Chemical products made in the state include soaps and other cleaners, pharmaceuticals, and paint.

Other important manufactured products of Maryland include primary metals, transportation equipment, and printed materials. Iron and steel, including steel wire, are Maryland's leading types of primary metals. Aerospace parts and products are major types of transportation equipment. Large numbers of newspapers are printed in the Baltimore area. Plants in southern Maryland print documents for the federal government.

Agriculture. Farmland covers about a third of Maryland's land area. The state has about 13,000 farms.

Livestock and livestock products provide about 60 percent of Maryland's farm income. *Broilers* (chickens from 5 to 12 weeks old) are Maryland's leading farm product. They account for more than half of the livestock income. Milk is Maryland's second most important livestock product. Frederick County leads the state in milk production. Other livestock products include beef cattle, eggs, hogs, and sheep.

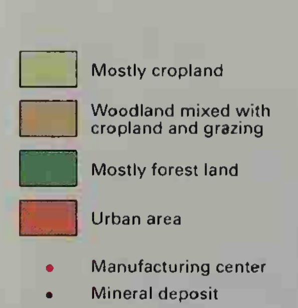
Crops in Maryland account for about 40 percent of farm income. Greenhouse and nursery products—including flowers, ornamental shrubs, and young fruit trees—make up the leading category of crops in Maryland. The state's leading field crops are soybeans, corn, and wheat. Maryland farmers also grow barley, hay, and tobacco. Sweet corn is the state's most valuable vegetable crop. Apples are the leading fruit crop.

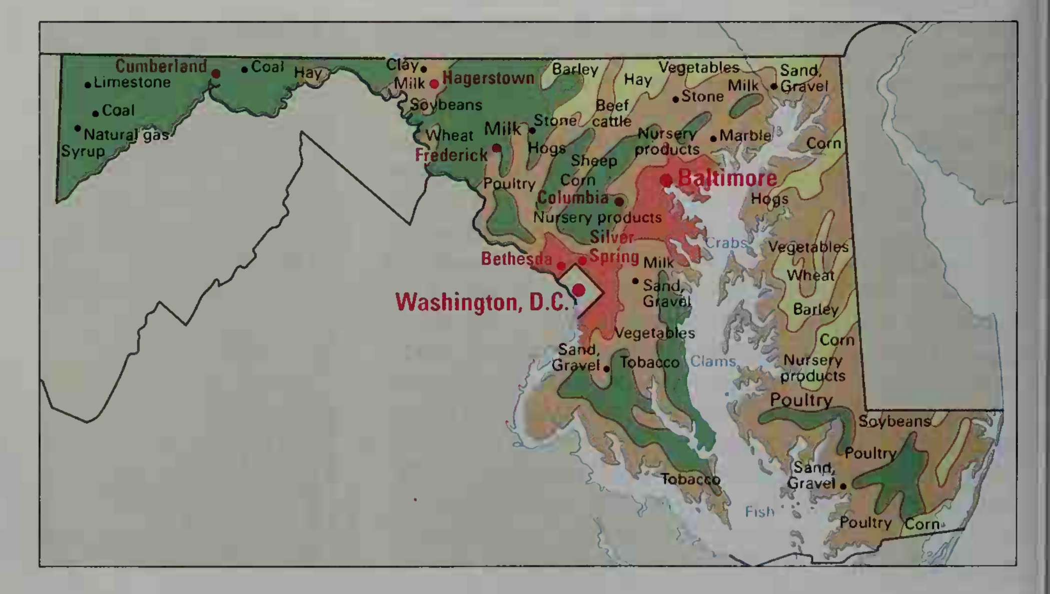
Mining. Crushed stone ranks as the most valuable mined product of Maryland. It is used mainly in the construction industry. The Piedmont region has the state's largest quarries. The Piedmont and western Maryland produce all the state's limestone and marble. Large quantities of sand and gravel come from pits in southern Maryland and the Eastern Shore. Allegany and Garrett counties produce all the state's coal and natural gas. Clay is mined in the Piedmont, as well as in the Eastern Shore and southern Maryland. The state's other mined products include peat and portland cement.

Fishing industry. The annual fish catch in Maryland is valued at about $65 million. Maryland ranks among the leading states in the production of blue crabs. Valuable catches in the waters of Chesapeake Bay include Atlantic croakers, bluefish, catfish, clams, crabs, menhaden, striped bass, and white perch. Fish caught in Atlantic coastal waters include bluefish, croakers, flounder, mackerel, marlin, shark, and striped bass.

Electric power. Plants that burn coal generate about 60 percent of the electric power used in Maryland. About 25 percent comes from nuclear plants. Hydroelectric plants and plants that burn petroleum or natural gas supply the rest of Maryland's electric power.

Transportation. Early transportation in the Maryland region was provided by steamboats traveling over Chesapeake Bay and its tributaries. In 1828, construction began on the Baltimore and Ohio Railroad. This railroad was the first in the Western Hemisphere to carry both passengers and freight. The Chesapeake and Delaware Canal was completed in 1829, connecting Chesapeake Bay with the Delaware River.





© Martin Rogers, Woodfin Camp, Inc.

Ships dock in Baltimore harbor, one of the largest natural harbors in the world. Baltimore is Maryland's chief industrial and trade center and one of the Atlantic Coast's leading ports.

Economy of Maryland

This map shows the economic uses of land in Maryland and where the leading farm and mineral products are produced. Major manufacturing centers are shown in red.

WORLD BOOK map

Maryland has about 30,000 miles (48,000 kilometers) of roads and highways. In 1963, the John F. Kennedy Expressway became the state's first modern tollway. It is part of Interstate 95, which runs between Florida and Maine. The William P. Lane, Jr., Memorial Bridge (formerly the Chesapeake Bay Bridge) links the Eastern and Western shores. Baltimore-Washington International Airport, near Baltimore, is Maryland's chief airport. Many people traveling to or from the Washington, D.C., area use it. Passenger trains serve Baltimore and Washington, D.C. Baltimore is a leading Atlantic Coast port.

Communication. The *Maryland Gazette,* published in Annapolis from 1727 to 1734, was the first colonial newspaper south of Philadelphia, and one of the first in the colonies. Today, Maryland publishers print about 100 newspapers, about 15 of which are dailies. *The Sun* in Baltimore is the largest daily. Publishers in the state also produce more than 350 periodicals.

In 1844, the first telegraph line in the United States opened between Baltimore and Washington, D.C. Maryland's oldest radio stations, WCAO and WFBR of Baltimore, began broadcasting in 1922. The state's first television station, WMAR-TV, was established in Baltimore in 1947. Today, Maryland has about 110 radio stations and 15 TV stations. Cable television systems and Internet providers service communities statewide.

Government

Constitution. The current Maryland Constitution was adopted in 1867, shortly after the American Civil War. Earlier constitutions dated from 1776, 1851, and 1864.

An *amendment* (change) in the Constitution may be proposed by the state legislature or by a constitutional convention. Legislative amendments must be approved by three-fifths of the members of both houses of the legislature. All amendments must be approved at the polls by a majority of those who vote on the amendment.

Executive. Maryland's governor serves a four-year term. The governor may be elected to an unlimited number of terms but may not serve more than two terms in a row.

The people elect the lieutenant governor, the attorney general, and the comptroller to four-year terms. The governor appoints the secretary of state, the adjutant general, and most members of state boards. The legislature elects the state treasurer to a four-year term.

Legislature, called the General Assembly, consists of a 47-member Senate and a 141-member House of Delegates. Each of the state's 47 legislative districts elects one senator and three delegates. All Maryland legislators serve four-year terms. Legislative sessions begin on the second Wednesday in January and are limited to 90 days. However, regular sessions may be extended 30 days by a three-fifths vote of the members of each

*Democratic Republican
†Also called the Know-Nothing Party.
‡Lieutenant Governor Blair Lee III served as acting governor from June 4, 1977, to Jan. 15, 1979.

house. The governor also may call to have a regular session extended. Special sessions may be called by the governor, or by the legislature if a majority of its members sign a petition requesting such a session.

Courts. Maryland's chief courts include the Court of Appeals, the Court of Special Appeals, and 24 circuit courts divided among eight judicial circuits. The Court of Appeals, the highest state court, hears cases appealed from the Court of Special Appeals and criminal cases involving the death penalty. It has seven judges. The Court of Special Appeals hears cases appealed from the circuit courts. This court consists of 13 judges. The circuit courts hear general cases. The number of judges in each circuit varies from 6 to 32. The governor appoints all appeals court and circuit court judges to serve for at least one year. At the next general election, appeals court judges may run for 10-year terms, and circuit court judges may run for 15-year terms. The governor also designates the chief judges who head each of the appeals courts.

Maryland also has a district court system. It consists of 12 courts that hear minor civil and criminal cases and traffic cases. A chief judge heads the system. The number of associate judges in each district varies from 3 to 26. The governor appoints all district court judges to 10-year terms, subject to confirmation by the Maryland Senate. The chief judge of the Court of Appeals appoints the chief judge of the District Court, who serves a 10-year term.

Local government in Maryland is centered in the state's 23 counties and in the city of Baltimore. Incorporated cities function as independent units of government. But all other areas in a county come under the jurisdiction of county government.

More than half of Maryland's counties are governed by elected boards of county commissioners. These boards serve executive and legislative functions. Board members are elected to four-year terms. The other counties are governed by county councils or county executives, or a combination of both. Council members are elected to four-year terms. Voters also choose such county officers as circuit court clerk, state's attorney, sheriff, and treasurer or financial director.

Baltimore, which is not part of any county, is governed by a mayor, an 18-member city council, and a council president. Most other cities use the mayor-council or commissioner form of government.

Counties in Maryland may adopt either of two forms of *home rule,* both of which allow them to govern many of their own affairs without control by the state legislature. Thirteen Maryland counties have adopted home rule. Incorporated cities in Maryland also have it.

Revenue. Taxes account for more than half of the state government's *general revenue* (income). Federal grants and programs also contribute significantly to the state's general revenue. Other sources of revenue include government services and a state lottery. Important sources of tax revenue include a personal income tax, a general sales tax, and taxes on motor fuels, corporate income, motor vehicle licenses, and insurance.

Politics. Maryland is strongly Democratic, with the greatest Democratic strength in Montgomery County, Prince George's County, and the city of Baltimore. The Republican Party is strong in only a few counties. Only five Republicans have ever served as governor of Maryland. But in presidential elections since 1920, about an equal number of Democratic and Republican candidates have won the state's electoral votes. For Maryland's electoral votes and its voting record in presidential elections, see **Electoral College** (table).

History

Indian days. Indians are known to have lived in the Maryland region by about 10,000 B.C. Early European explorers found Algonquian Indians and a few Susquehannock in the region. The Algonquian tribes included the Choptank, Nanticoke, Patuxent, Portobago, and Wicomico. Most of the Indians left the region during the early years of colonial settlement. But they gave their names to many Maryland rivers, towns, and counties.

Exploration and settlement. Pedro Menéndez de Avilés, the Spanish governor of Florida, explored Chesapeake Bay in 1572. He was one of the first Europeans to visit the Maryland region. In 1608, Captain John Smith of Virginia sailed northward up Chesapeake Bay into the Maryland region. Smith wrote a description of what he saw. In 1631, William Claiborne, also of Virginia, opened a trading post on Kent Island in the bay. Claiborne's was the first colonial settlement in the Maryland region.

In 1632, King Charles I of England granted the Maryland region to George Calvert, the first Lord Baltimore. But Calvert died before the king signed the charter. King Charles then chartered the region to Calvert's son, Cecilius, the second Lord Baltimore. The region was named *Maryland* in honor of Queen Henrietta Maria, the wife of Charles. Cecilius Calvert sent colonists to Maryland on two ships, the *Ark* and the *Dove.* In 1634, the ships anchored in the Potomac River. The colonists established St. Marys City (now St. Mary's City) near the southern tip of the Western Shore.

Colonial days. Cecilius Calvert appointed his brother, Leonard, as governor of the Maryland colony. Cecilius encouraged the colonists to suggest laws and to assist his brother in the colony's administration. Cecilius was a Roman Catholic, but he had to support the Church of England. However, he wanted freedom of worship for those of his faith, and he also wanted people of other faiths to settle in Maryland. He believed that religious restrictions would interfere with the colony's growth and development. In 1649, the colonial assembly approved Cecilius Calvert's draft of a religious toleration law, granting religious freedom to all Christians. After the law was passed, a band of Puritans fled from Virginia and came to Maryland. Maryland became famous for its religious freedom.

William Claiborne's trading settlement on Kent Island was part of the colony. But Claiborne refused to recognize Calvert's authority. In 1654, Claiborne led a group of Protestant settlers who overthrew Calvert's government. Claiborne controlled Maryland for four years.

Historic Maryland

Francis Scott Key wrote "The Star-Spangled Banner" after watching the British bombard Baltimore's Fort McHenry in 1814.

The first American coal-burning steam engine, the *Tom Thumb,* operated on the Baltimore and Ohio Railroad in Baltimore during the summer of 1830. Peter Cooper, an American inventor, designed and built it.

The first telegraph line in America was opened in 1844. The words "What hath God wrought" were sent by inventor Samuel F. B. Morse from Washington, D.C., to Baltimore.

The William P. Lane, Jr., Memorial Bridge connects Maryland's two shores. The $4\frac{1}{3}$-mile (7-kilometer) bridge opened in 1952. It was first called the Chesapeake Bay Bridge.

WORLD BOOK illustrations by Kevin Chadwick

Important dates in Maryland

1572 Pedro Menéndez de Avilés, the Spanish governor of Florida, explored Chesapeake Bay.

1608 Captain John Smith explored Chesapeake Bay.

1631 William Claiborne established a trading post on Kent Island.

1632 King Charles I of England granted the Maryland charter to Cecilius Calvert, second Lord Baltimore.

1634 The first European settlers arrived in Maryland.

1649 Maryland passed a religious toleration act.

1654 William Claiborne seized control of the colony.

1658 Cecilius Calvert regained control.

1691 England assumed direct rule of the colony and sent a royal governor, who arrived in 1692.

1715 The Calvert family regained proprietorship of the colony.

1767 Mason and Dixon completed their survey of the Maryland-Pennsylvania boundary, begun in 1763.

1774 Marylanders burned the *Peggy Stewart* and its cargo of tea in protest against the Boston Port Act.

1776 Maryland declared its independence.

1776-1777 The Continental Congress met in Baltimore.

1783-1784 The Continental Congress met in Annapolis.

1786 The Annapolis Convention met.

1788 Maryland became the seventh state on April 28.

1791 Maryland gave land for the District of Columbia.

1814 Francis Scott Key wrote "The Star-Spangled Banner" during the British bombardment of Fort McHenry.

1828 Building of the Baltimore and Ohio Railroad began.

1845 The U.S. Naval Academy was founded at Annapolis.

1850 The National (Cumberland) Road, west from Cumberland, was completed.

1862 Federal forces drove back the Confederates from Antietam Creek near Sharpsburg.

1864 A constitution abolishing slavery was adopted.

1904 The Great Fire destroyed Baltimore's downtown area.

1919-1933 Maryland resisted the nation's prohibition laws and became known as the *Free State.*

1952 The Chesapeake Bay Bridge (now the William P. Lane, Jr., Memorial Bridge) was opened to traffic.

1985 Maryland, in cooperation with Delaware, Pennsylvania, Virginia, and Washington, D.C., began a project to clean up polluted Chesapeake Bay.

On orders from the English government, Claiborne returned Maryland to Calvert in 1658. Calvert promised to uphold the religious freedoms established in 1649. But many Protestants in Maryland resented a Roman Catholic as proprietor of the colony. In 1689, the Protestant Association, a group led by John Coode, seized control of the colony. Coode demanded that England take over the government of Maryland. As a result, the English crown appointed a royal governor in 1691. Early in 1692, the governor arrived to rule the colony.

The Calvert family regained control of Maryland in 1715 under Benedict Leonard Calvert, the fourth Lord Baltimore, who was a Protestant. In 1718, Roman Catholics in Maryland lost the right to vote. They did not regain this right until 1776. Maryland remained in the hands of the Calverts until the Revolutionary War.

Maryland prospered during the years before the war. Tobacco farming in the colony became profitable. Numerous colonists grew wealthy and built beautiful mansions. Maryland's population grew rapidly. In the 1700's, Maryland and Pennsylvania quarreled over the boundary line between them. In 1763, both colonies agreed to have Charles Mason and Jeremiah Dixon of England survey the land. The survey was completed in 1767, and the boundary became known as Mason and Dixon's Line.

The Revolutionary War. During the mid-1700's, Britain found itself deeply in debt. To help raise money, Britain placed severe taxes and trade restrictions on the American Colonies. The people of Maryland, like those of the other colonies, opposed these measures. Marylanders resisted the Stamp Act of 1765 (see **Stamp Act**). In 1774, colonists in Maryland protested the Boston Port Act. This act was a British attempt to punish the people of Boston for the Boston Tea Party (see **Boston Port Act**). Marylanders burned the British ship *Peggy Stewart* and its cargo of tea in Annapolis.

In 1774, delegates from Maryland attended the First Continental Congress in Philadelphia. They supported a policy forbidding the colonists to trade with Britain. The Revolutionary War in America began in Massachusetts in April 1775. That May, the Second Continental Congress met in Philadelphia, and on July 2, 1776, Maryland delegates voted for independence. Maryland adopted its first constitution on Nov. 8, 1776. In December 1776, the Continental Congress moved to Baltimore because the British threatened Philadelphia. The Congress remained there until the following March. Thomas Johnson, Maryland's first governor under its Constitution, took office on March 21, 1777.

Maryland troops fought throughout the Revolutionary War. Baltimore industries built ships and cannons for the colonial forces. But little fighting took place on Maryland soil. British Vice Admiral Richard Howe sailed up Chesapeake Bay in 1777 and landed troops at the mouth of the Elk River. The troops moved into Pennsylvania that same year, and they defeated General George Washington in the Battle of Brandywine.

Statehood. During the war, the Continental Congress formed a government of the United States under the Articles of Confederation. Some of the states claimed western land that extended beyond their colonial boundaries. Maryland refused to sign the Articles of Confederation until the states promised to turn these western lands over to the United States government. Maryland signed the Articles of Confederation on March 1, 1781.

After the war, the Congress of the Confederation accepted Maryland's invitation and met at the Maryland State House in Annapolis from November 1783 to June 1784. George Washington resigned his commission as commander in chief of the Continental Army in the State House. In the same building, Congress ratified the Treaty of Paris, ending the Revolutionary War.

During the early 1780's, Maryland and Virginia disagreed over navigational rights in Chesapeake Bay and on the Potomac River. In 1785, commissioners from the two states approved the Mount Vernon Compact, which allowed both states to benefit from use of the waterways. Another interstate conference, the Annapolis Convention, met in Annapolis on Sept. 11, 1786, to discuss trade and commerce problems. When the meeting attracted representatives from only five states, the delegates called for a meeting of all the states in Philadelphia in 1787. The delegates who met in Philadelphia wrote the Constitution of the United States. Maryland *ratified* (approved) the Constitution on April 28, 1788, and became the seventh state of the Union. In 1791, Maryland gave land to Congress for the District of Columbia, the new national capital.

The War of 1812 and industrial development. Several battles of the War of 1812 were fought in Maryland. In 1813, the British raided a number of Maryland towns and farmhouses along Chesapeake Bay. During the summer of 1814, a large British force under General Robert Ross sailed up the Patuxent River. Ross's troops defeated American forces in the Battle of Bladensburg on Aug. 24, 1814. The British moved on to Washington, D.C., that same day. They burned the Capitol and other government buildings.

On Sept. 12, 1814, the British attacked Baltimore. British troops landed at North Point, southeast of Baltimore at the mouth of the Patapsco River. British ships sailed up the river and fired on Fort McHenry. But American forces defended the city and drove the British out of Maryland. The Battle of Baltimore inspired Francis Scott Key to write "The Star-Spangled Banner," which later became the national anthem of the United States. See **Star-Spangled Banner**.

During the early and middle 1800's, Baltimore grew into an important industrial city. It became a leading seaport and one of the nation's shipbuilding centers. Goods were shipped between Baltimore and the West on the Baltimore and Ohio Railroad and on the Chesapeake and Ohio Canal. Goods were shipped eastward on the Chesapeake and Delaware Canal. In 1830, Peter Cooper built the *Tom Thumb,* the first coal-burning American steam locomotive. The Baltimore and Ohio Railroad used the *Tom Thumb* between Baltimore and Ellicott's Mills (now Ellicott City). The *De Rosset,* the first oceangoing iron steamship built in the United States, was completed in Baltimore in 1839. Maryland adopted a new constitution in 1851, its first since 1776.

The Civil War. Maryland was a slave state, but it also was one of the original 13 states of the Union. When the American Civil War began in 1861, Marylanders were divided in their loyalties between the Union and the Confederacy. After Virginia joined the Confederacy, the fate of Washington, D.C., depended on whether Maryland

Lithograph (1887); Maryland Historical Society

The Battle of Antietam halted General Robert E. Lee's first invasion of the North during the Civil War. The bloody battle was fought near Sharpsburg on Sept. 17, 1862.

remained in the Union. If Maryland joined the Confederacy, Washington, D.C., would be surrounded by Confederate territory. Union forces rushed across Maryland to defend the nation's capital. Although Maryland remained in the Union, many Marylanders joined the Confederate armies.

Several Civil War battles were fought on Maryland soil. In 1862, General Robert E. Lee's Confederate troops invaded Maryland. Union forces fought them in the Battle of Antietam, near Sharpsburg, on September 17. That day, more than 12,000 Union soldiers and 10,000 Confederates were killed or wounded. Lee withdrew to Virginia the next day. In June 1863, Lee led his troops across Maryland into Pennsylvania, where he was defeated in the Battle of Gettysburg. In 1864, Confederate General Jubal A. Early crossed the Potomac River into Maryland. He defeated a Union division in the Battle of Monocacy, near Frederick, on July 9. Early's forces advanced to within sight of Washington, D.C., before Union forces drove them back.

In 1864, Maryland adopted a constitution that abolished slavery. The new Constitution also placed harsh penalties on Marylanders who had supported the Confederate cause. A less severe constitution was adopted in 1867 and is still in effect.

Maryland maintained its industrial and commercial development after the Civil War. Baltimore, already a great industrial city, became a well-known cultural center in the middle and late 1800's. Philanthropists established many important cultural institutions, including the Peabody Conservatory of Music (now the Peabody Institute) in 1857, Johns Hopkins University in 1876, and the Enoch Pratt Free Library in 1886.

The early 1900's. Maryland's industrial expansion continued into the 1900's. The state's factories and shipyards expanded greatly after the United States entered World War I in 1917. The U.S. Army established the Aberdeen Proving Ground, its first testing center, along the northwest shore of Chesapeake Bay in 1917.

In 1919, the U.S. Congress passed a law making it illegal to manufacture, sell, and transport alcoholic beverages. Marylanders were among the leading opponents of prohibition because they considered it a violation of their state's rights. As a result, Maryland became known as the *Free State.* This nickname is still sometimes used to honor Maryland's traditions of political and religious freedoms.

The Great Depression of the 1930's struck the industrial city of Baltimore particularly hard. Maryland passed social and welfare laws in cooperation with the U.S. government to ease hardships. Between 1935 and 1938, the U.S. government built the city of Greenbelt to provide housing for moderate-income families. In 1937, the state legislature approved Maryland's first income tax law.

The mid-1900's. During World War II (1939-1945), manufacturing activity increased greatly in Maryland. Thousands of workers came to the state from the Appalachian mountain region and other parts of the South.

After the war, Maryland's industry and population continued to grow, and the state improved its transportation systems. Baltimore's Friendship International Airport (now Baltimore-Washington International Airport) opened in 1950. Between 1952 and 1963, the state completed the Baltimore Harbor Tunnel, the Chesapeake Bay Bridge (now the William P. Lane, Jr., Memorial Bridge), the John F. Kennedy Expressway, and an expressway connecting Baltimore and Washington. The town of Columbia, a community completely designed by city planners, was founded in the early 1960's.

The growth of Maryland's urban population created political problems. Until the 1960's, voters in thinly populated rural areas were electing most of the state's legislators. Between 1962 and 1966, Maryland *reapportioned* (redivided) its election districts for more equal representation.

Maryland expanded its school system during the 1960's and 1970's. The University of Maryland, which has its main campus in College Park and branches in Baltimore and Princess Anne, opened a branch in Catonsville as well. Several state teachers' colleges became general state colleges, and many two-year community colleges opened.

In 1967, Spiro T. Agnew became the fifth Republican governor in Maryland's history. In 1969, Agnew took office as vice president of the United States under President Richard M. Nixon. Nixon and Agnew won reelection in 1972. But Agnew resigned as vice president in 1973. He left the office when a federal grand jury investigated charges that he had participated in widespread graft as an officeholder in Maryland and as vice president (see Agnew, Spiro T.).

The late 1900's. Maryland's industrial growth and its location on Chesapeake Bay have tied the state economically to the northeastern industrial states. Many new cities, suburbs, and industrial communities grew up between Baltimore and Washington. The state faced the challenge of providing these expanding areas with schools, water and power supplies, and other services. In 1972, Maryland voters approved a state lottery to raise money for the state government. State officials also emphasized the need to solve the problems of air and water pollution.

The rising population during and after World War II brought changes in housing and education that are still

going on in Maryland. Thousands of the people who moved to Maryland from the South were African Americans. As they settled in Baltimore, increasing numbers of other families moved to the city's suburbs. At this time, Maryland public schools were segregated. However, in 1954, the Supreme Court of the United States ruled that compulsory segregation of public schools was unconstitutional. Baltimore desegregated its public schools almost immediately. School desegregation in the rest of the state proceeded slowly but steadily, and all of Maryland's school systems are now integrated.

In 1985, Maryland's government began a major effort to clean up Chesapeake Bay. This project is expected to continue beyond the year 2010. The cleanup involves close cooperation with Virginia, Pennsylvania, Delaware, and Washington, D.C.

Recent developments. Today, Maryland is a national center for space research, development, and production. Basic planning for space projects is carried out at the National Aeronautics and Space Administration's Goddard Space Flight Center located in Greenbelt.

Maryland System, University of, is a coeducational, state-assisted system of higher education. It includes 11 degree-granting institutions and 3 major research and service centers.

Five of the University of Maryland System's degree-granting institutions are located in the Baltimore region. They are the University of Baltimore, the University of Maryland at Baltimore, Coppin State College, Towson University, and the University of Maryland Baltimore County.

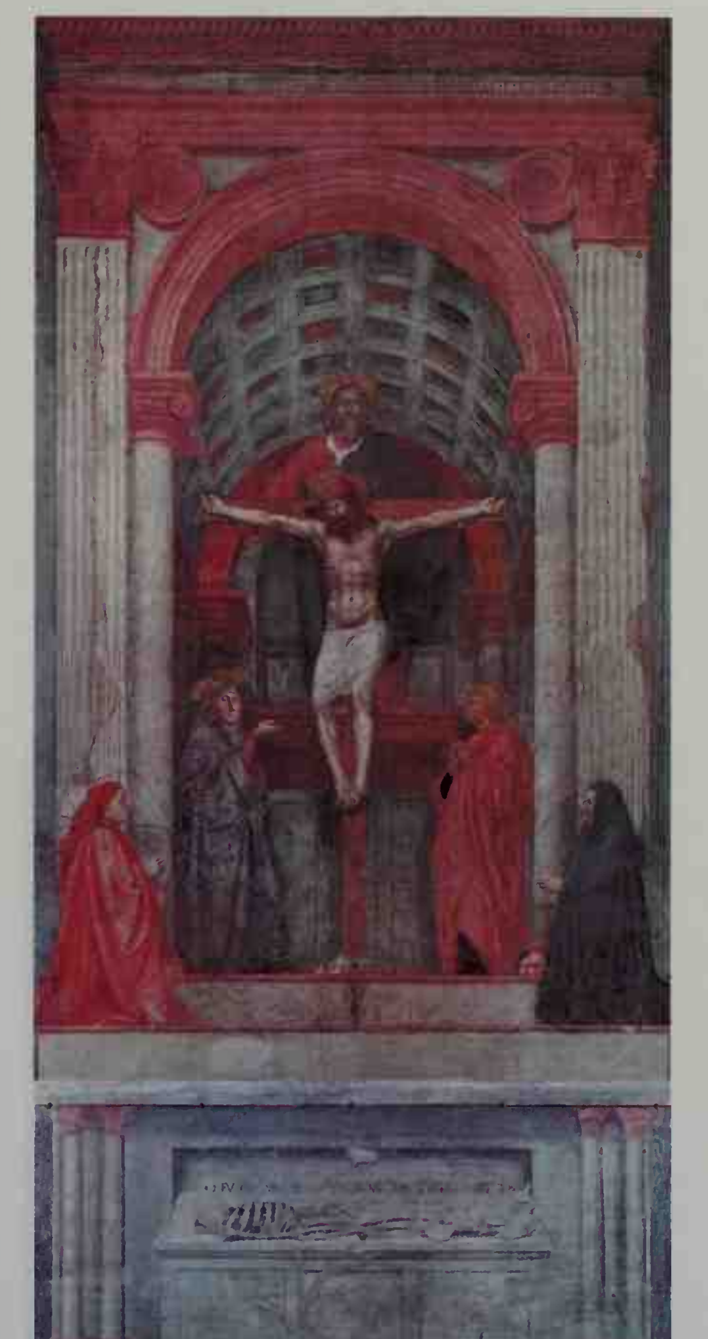
The system's other degree-granting institutions are Bowie State University, in Bowie; Frostburg State University, in Frostburg; Salisbury State University, in Salisbury; the University of Maryland College Park, in College Park; the University of Maryland Eastern Shore, in Princess Anne; and the University of Maryland University College, headquartered in College Park.

University of Maryland

The University of Maryland campus in College Park, Maryland, lies in a wooded area near Washington, D.C.

The various campuses of the University of Maryland System offer instruction in many fields, including arts and humanities, journalism, business, education, social work, engineering, science, health science, and law. Each campus grants bachelor's and master's degrees. Four campuses also grant doctor's degrees in certain fields.

The University of Maryland College Park is the largest school in the system. The College Park campus offers 125 undergraduate majors and more than 80 graduate programs. The University of Maryland at Baltimore, founded in 1807, is one of the nation's oldest and largest centers of graduate and professional education. The University of Maryland University College offers part-time programs at about 20 locations in Maryland, Virginia, and Washington, D.C. Its European and Asian divisions offer degree programs to United States military families in more than 20 countries.



The University of Maryland System's major research and service centers are the Center for Environmental and Estuarine Studies, the Maryland Biotechnology Institute, and the Maryland Institute for Agriculture and Natural Resources. The Maryland legislature established the University of Maryland System in 1988.

Critically reviewed by the University of Maryland System

Masaccio, *muh SAH chee OH* (1401-1428), an Italian painter, was one of the first great masters of the Italian Renaissance. He brought a new naturalness to painting through the use of strong modeling and lifelike poses. Masaccio's *The Holy Trinity* is the first monumental painting to use the newly invented device of perspective. In addition, the effects of light and atmosphere gave a new realism to his work. Masaccio's art was admired by many famous Italian Renaissance painters, including Michelangelo and Raphael.

Masaccio was born in San Giovanni di Valdarno, Italy, near Florence. His real name was Tommaso Cassai, but he was nicknamed Masaccio—which means *simple Tom*—because of his absent-mindedness. He studied art in Florence and gained recognition as a master painter by the time he was 21.

Masaccio's most important work is a series of fres-

The Holy Trinity with the Virgin and Saint John (1425), a fresco in the church of Santa Maria Novella, Florence, Italy; SCALA

A painting by Masaccio shows his ability to create solid-looking forms through the use of perspective and light and shade.

coes in the church of Santa Maria del Carmine in Florence. One of the paintings in this series, *The Tribute Money,* shows his advanced use of form and perspective. It is reproduced in color in the **Painting** article.

Masada, *muh SAHD uh* or *muh SAYD uh,* was a historic Jewish fortress that stood on a huge rock in Judea (now southern Israel). The rock is also called *Masada,* the Hebrew word for *mountain fortress.* According to Jewish tradition, 960 Jewish patriots killed themselves at Masada in A.D. 73. They committed suicide to avoid having to surrender to Roman troops. For many Israelis, this devotion to liberty is a national symbol called the "spirit of Masada."

The rock is about 20 miles (32 kilometers) southeast of Hebron. For location, see **Dead Sea** (map). Masada has cliffs that rise 1,400 feet (427 meters). The top of the rock is flat and measures about 1,900 feet (579 meters) long and 650 feet (198 meters) wide.

The Jewish leader Jonathan established the fortress during the Hasmonean Revolt (167-142 B.C.). During that period, the Jews successfully fought for their independence from the Syrians. In 63 B.C., the Romans gained control of Judea. Herod the Great, who was appointed king of Judea by the Romans in 40 B.C., reinforced the fortress and also built two palaces on the rock.

Jewish patriots called *Zealots* captured Masada in A.D. 66, when the Roman governor Gessius Florus ruled Judea. According to tradition, the Jews burned the camp and committed suicide in A.D. 73, just before the Romans recaptured the fortress. Only two women and five children remained alive. Byzantine monks settled briefly on Masada during the 400's and 500's.

From 1963 to 1965, an archaeological expedition headed by Yigael Yadin of Israel discovered various ruins of ancient Masada, including Herod's palaces. The expedition also found armor, Biblical and other scrolls, coins, ritual baths, and a synagogue. Today, many tourists and Israeli citizens visit Masada. Jane S. Gerber

Masada was a Jewish fortress in what is now southern Israel. In A.D. 73, more than 900 Jewish patriots committed suicide there rather than surrender to Roman troops.

Masai. See Maasai.

Masaryk, *MAS uh rihk,* was the family name of two Czech statesmen, father and son.

Tomáš Garrigue Masaryk, *TAW mahsh guh REEG* (1850-1937), was a scholar and a statesman who, with his student Eduard Beneš, founded Czechoslovakia in 1918 (see **Beneš, Eduard**). Masaryk became the country's first president in 1918 and served until 1935.

Masaryk began his career in 1891 in the Austro-Hungarian parliament, where he fought for the rights of Slavic minority groups. When World War I broke out in 1914, he fled to Switzerland and then to England. In his absence, the Austro-Hungarian government in 1916 sentenced him to death for high treason.

Masaryk came to the United States in 1917 to seek support for an independent Czechoslovakia. He met with President Woodrow Wilson, and with Czechs, Slovaks, and Ruthenes who lived in America. Masaryk gained his objective when the Allied armies defeated Austria-Hungary in 1918. The Republic of Czechoslovakia was created from a part of Austria-Hungary.

Masaryk's 17-year term as president of the Czechoslovak republic was generally a time of peace and prosperity. But the Slovaks gradually became restless, because they thought he had not fulfilled a promise to grant them self-government. Also, the German minority group turned increasingly to Nazi Germany for sympathy and help. Masaryk resigned in 1935 because of poor health and died on Sept. 14, 1937. Beneš succeeded him.

Masaryk was born on March 7, 1850, on an estate in Moravia, where his father served as a coachman to the Austrian emperor, Francis Joseph. He was educated at the universities of Vienna and Leipzig. He taught philosophy and sociology at Charles University in Prague.

Jan Garrigue Masaryk, *yahn guh REEG* (1886-1948), the son of Tomáš, entered the Czechoslovak foreign service in 1919 and served as minister to London from 1925 to 1938. In 1940, he became foreign minister of the Czechoslovak government-in-exile. When the government returned to Czechoslovakia after World War II (1939-1945), Masaryk kept the post of foreign minister. He fought a losing battle from 1945 to 1948 against the increasing Communist domination of Czechoslovakia.

Masaryk died mysteriously on March 10, 1948. His body was found in a courtyard, three stories under his apartment window in Prague. It is undetermined whether he was murdered or killed himself in protest against the Communist seizure of the government in February 1948. He was born on Sept. 14, 1886, in Prague.

Mascagni, *mahs KAH nyee,* **Pietro,** *PYEH traw* (1863-1945), was an Italian opera composer. He was born on Dec. 7, 1863, in Livorno, where he also studied music. In 1888, Mascagni entered a one-act opera in a competition and won first prize. The opera, *Cavalleria rusticana,* was a drama of raw passion in a Sicilian village. It was presented in Rome in 1890 and made Mascagni world famous as the leader of a realistic, boisterous operatic

style called *verismo* (see **Opera** *[Cavalleria rusticana]*). Mascagni never came close to repeating his first success. He composed 15 operas, but the only other one still performed is *L'Amico Fritz* (1891).

Mascagni died on Aug. 2, 1945, a disappointed and almost discredited composer. He seemed to lack the creative imagination to overcome public expectations after the worldwide success of *Cavalleria*. The opera remains popular because of its emotional melodies and the theatrical force of its *libretto* (words). Charles H. Webb

Masefield, John (1878-1967), was an English poet, novelist, critic, and playwright. He was appointed poet laureate of the United Kingdom in 1930 (see **Poet laureate**). His 37-year term as poet laureate is among the longest and most distinguished in English literature.

Masefield was born on June 1, 1878, at Ledbury in what is now the county of Hereford and Worcester. He was apprenticed as a seaman when he was 13 and spent four years at sea. His experiences influenced his poetry and his fiction. Masefield is most celebrated as a sea poet and as one who sings of "the dust and scum of the earth" and of "the maimed, of the halt and the blind in the rain and the cold." Many of his works tell tales of love and tragedy among the people of Shropshire and among vagabonds and men of the sea.

Masefield wrote more than 100 books. He first won recognition for his collection of poetry *Salt-Water Ballads* (1902). His best-known works are the long narrative poems *The Everlasting Mercy* (1911), *The Widow in the Bye Street* (1912), *Dauber* (1913), and *Reynard the Fox* (1919). His individual poems include "A Consecration," "On Growing Old," and "Sea Fever." His popular novels include the adventure tales *Sard Harker* (1924) and *The Bird of Dawning* (1933). Masefield also wrote an autobiography, *So Long to Learn* (1952). He died on May 12, 1967. William Harmon

Masekela, *ma seh KAY luh,* **Hugh** (1939-), is a well-known South African jazz trumpet player. Masekela has also been successful as a bandleader and composer.

Hugh Rampolo Masekela was born on April 4, 1939, in Witbank, in what is now the South African province of Mpumalanga. He dropped out of school in 1955 to form a jazz group called the Merry Makers. Masekela gained his first recognition as a member of the band Jazz Epistle Verse I with pianist Adbullah Ibrahim (also called Dollar Brand) in 1959 in Johannesburg. The band blended the music of South Africa's black townships and their churches with American big band sounds. Jazz Epistles was the first black band to make a long-playing record album in South Africa.

With the assistance of the African American entertainer Harry Belafonte, Masekela left South Africa in 1960. He studied music briefly in England and at the Manhattan School of Music in New York City. He led a jazz quartet in the United States in the 1960's and had a number-one hit recording in "Grazing in the Grass" (1968). Masekela was married to the South African singer Miriam Makeba from 1964 until they divorced in 1968.

Masekela lived and performed in Africa from 1972 to 1986, when he returned to the United States. He was co-composer of the stage musical *Sarafina!* (1987). The show, which protested the South African government's racial policies, became a hit in the United States and was made into a motion picture in 1992. Frank Tirro

Maser, *MAY zuhr,* is a device that generates or amplifies microwaves. The word *maser* stands for *m*icrowave *a*mplification by *s*timulated *e*mission of *r*adiation.

The essential part of a maser is a substance that has been put into an *excited* (higher energy) state. In this state, the atoms of the substance are able to radiate energy of a particular frequency when *stimulated* (triggered) by a microwave of the same frequency. The energy released by the atoms is added to the stimulating wave, amplifying it. In the *ammonia maser,* heat is used to excite ammonia gas. The first ammonia maser was built in the United States in 1954. Masers are used for the amplification of weak microwave signals from distant stars and for communications. William B. Case

Maseru, *MAZ uh ROO* (pop. 109,382), is the capital of Lesotho. It lies near the northwest border. For location, see **Lesotho** (map). A railroad links Maseru with cities in South Africa, which surrounds Lesotho. The city is the seat of government for the country and has a hospital and technical training school where manual and local arts are taught. Most of the people who live in Maseru are black Africans called *Sotho.* Maseru's other people include Europeans and black refugees from South Africa. Bruce Fetter

Mash. See **Whiskey; Brewing.**

Mask is a covering that disguises or protects the face. Most masks worn as a disguise have the features of a human being or an animal. In the United States, such masks are generally worn for fun on Halloween and other special occasions. Various kinds of protective masks serve different purposes. For example, a welder wears a steel mask with a special lens that protects the eyes from the intense light produced by welding.

Throughout history, people have used masks as a disguise. By hiding the features of the face, masks prevent other people from making judgments about the wearer's personality and character. Most of these masks not only hide the identity of the wearer but supposedly also give the masked person magic powers. Such masks represent gods or spirits. The custom of wearing masks probably began with animal heads worn by people. Such masks may have been used in hunting. They probably served as disguises and as magic symbols to make the hunt successful. However, masks may have developed from the practice of marking the face with colorful designs that had magic powers.

Some masks are carved from wood or stone. Others are made of cloth, grass, hide, leather, metal, paper, or shell. Some masks have realistic human or animal features, but others give the wearer a grotesque appearance. Many masks represent the art forms of a society. The masks may involve highly developed craft skills and may be painted with symbolic designs and colors.

This article discusses masks worn for other purposes than to protect the face. Such masks may be divided into four groups according to their major use: (1) ceremonial masks, (2) theatrical masks, (3) burial masks and death masks, and (4) festival masks. These categories overlap, however. Many burial masks, for example, serve ceremonial purposes.

Ceremonial masks developed from the belief of many primitive societies that gods controlled the forces of nature. Dancers at various ceremonies wore masks

Marvin Newman, Woodfin Camp, Inc.

Colorful masks are worn in many countries during *carnival,* a period of merrymaking just before Lent. Carnival celebrations include such festivities as masked balls, parades, and dancing in the streets. The drummers shown above are marching in a carnival procession in Basel, Switzerland.

Field Museum of Natural History (WORLD BOOK photo)

Some masks have skirts that cover much of the wearer's body. The mask on the left was made by the Cubeo Indians of Colombia; the one on the right, by the Senesi people of Papua New Guinea.

Field Museum of Natural History (WORLD BOOK photo)

Many masks have grotesque features. A demon mask from Sri Lanka, *left,* has fangs and bulging eyes. A Chinese theatrical mask, *right,* represents an official of hell in a religious play.

that represented these gods. A mask made its wearer unrecognizable, and so he seemed to almost lose his identity and become the spirit itself. When these ceremonial dancers wore such masks, the people believed that the gods were actually present. If people wore a mask that represented a certain spirit, the powers of that spirit supposedly remained for many generations. After the wearer of the mask died, another man took his place in wearing it.

Many Indian tribes of North America used masks in their ceremonies. Male members of the False Face Society of the Iroquois Indians wore wooden masks at ceremonies held to heal the sick. The False Face performers visited villages and were often escorted by male clowns called Shuck Faces, who wore masks made of braided corn husks. Adults welcomed the masked visitors, but most of the children became terrified.

The Indians of the northwest Pacific Coast used masks with a movable mouth and eyelids. They wore these masks in ceremonies honoring certain animals. Many of these masks actually consisted of two or three masks. The outer mask of a double mask—or the two outer masks of a triple mask—represented a bird or some other animal. The outer mask could be folded back, revealing a mask of a human face. Such masks are related to the belief that some human beings had the power to change into animals and back again. This belief was common among many societies.

Some peoples in New Guinea, West Africa, the Amazon region of South America, and the southwestern United States still use masks in spiritual ceremonies. For example, the Hopi Indians of Arizona have special ceremonies in which male dancers wear masks that represent their ancestors or certain gods. The people believe the ceremonies bring visits from these beings, who appear in the form of spirits called *Kachinas.* Kachinas produce rain, make corn grow, and sometimes whip young boys and girls who are about to be formally initiated into adulthood. The masks are also called Kachinas.

Some primitive peoples wore grotesque masks when they went to war. They believed that the appearance of these masks, which represented their gods, would frighten the enemy.

Theatrical masks. The ancient Greeks used masks in their classical drama, which developed from religious ceremonies of earlier times. Masked singers and dancers represented gods and mythological heroes. The masks also expressed anger, joy, love, and other emotions. These masks were needed to let the audience follow the action of the play. The theaters were so large that many people could not see the facial expressions of the actors. Also, simple amplifiers built into the masks helped carry an actor's voice a great distance.

Since ancient times, Chinese drama has used masks to help portray types of characters. The color of the mask plays an important part in the drama. For example, red represents a loyal person, and white represents a cruel one. A type of dramatic entertainment called a *masque* developed from the use of masks as disguises in musical pageants during the Renaissance (see **Masque**). A type of Japanese play called *no* uses many masks, each representing a different emotion.

Burial masks and death masks have had an important role in many societies. The ancient Egyptians put a personalized mask over the face of every mummy, or they made the mask part of the mummy case. The mask supposedly identified the dead person so that the wandering soul could always find its body.

Some peoples still use masks in ceremonies relating to death. In an annual mourning ceremony held on New Ireland, an island near Australia, dancers wear masks that represent certain dead persons. The spirits of the dead supposedly return during the ceremony.

The Aleuts, who live on the Aleutian Islands of Alaska, put a mask on people after they die. They believe the mask protects the dead from the dangerous glances of spirits. Some Indian tribes of the Andes Mountains of South America also follow this custom.

In Western countries, death masks are sometimes used to preserve the features of the dead. A plaster cast is made of the face, and plaster likenesses are made from this mold. Famous death masks include those of Ludwig van Beethoven and Napoleon Bonaparte.

Granger Collection

Museum of the American Indian, New York City

Burial masks are important in many societies. The Egyptian king Tutankhamen's golden burial mask was made from a cast of his face taken after he died. The Aleuts—a people native to Alaska—cover the faces of their dead with a wooden mask.

Festival masks developed from masks used in religious ceremonies. Some North American Indian tribes continue to use such masks in harvest festivals. Processions and festivals in China, India, and other countries also include masked people. In the United States, people wear masks at Mardi Gras. Alan Dundes

For pictures of masks, see **Africa**; **Drama** (Greek drama); **Indian, American**.

Maslow, *MAS loh,* **Abraham Harold** (1908-1970), was an American psychologist whom many people consider the founder of a movement called *humanistic psychology.* The movement developed as a revolt against behaviorism and psychoanalysis, the two most popular psychological views of the mid-1900's. Humanistic psychologists believe individuals are controlled by their own values and choices and not by the environment, as behaviorists think, or by unconscious drives, as psychoanalysts believe. Maslow stressed the importance of studying well-adjusted people in society instead of only disturbed ones.

Maslow identified several levels of human needs, the most basic of which must be satisfied before the next levels can be fulfilled. The most basic needs are bodily drives, such as hunger and thirst. Succeeding levels include the needs for safety and love. The highest need is for the fulfillment of one's unique potential, which Maslow called *self-actualization.*

Maslow was born in New York City. He wrote several books, including *Motivation and Personality* (1954) and *Toward a Psychology of Being* (1962). Ricardo B. Morant

Mason (bricklayer). See **Building trade.**

Mason (Freemason). See Masonry.

Mason, Charles. See **Mason and Dixon's Line.**

Mason, George (1725-1792), was a Virginia statesman who wrote the first American bill of rights, the Virginia Declaration of Rights of 1776. In 1787, Mason played an important role in the Constitutional Convention, though he refused to sign the final draft of the United States Constitution. Mason held few public offices, but his writings and leadership had great influence.

Virginia Museum of Fine Arts, Gift of K. E. Bruce

George Mason

Perhaps Mason's most important work was his writing of the Virginia Declaration of Rights. Thomas Jefferson drew on this document when he wrote the Declaration of Independence. James Madison also used Mason's ideas in 1789 when he drafted the 10 constitutional amendments that became the Bill of Rights.

His constitutional views. Mason played an active role in creating the Constitution but disagreed with parts of it. For example, he favored a system of *proportional representation,* in which a state's population determines the number of its members in Congress. But he eventually supported the compromise that gave each state an equal vote in the Senate and a proportional vote in the House of Representatives.

Mason objected strongly to the compromise that al-

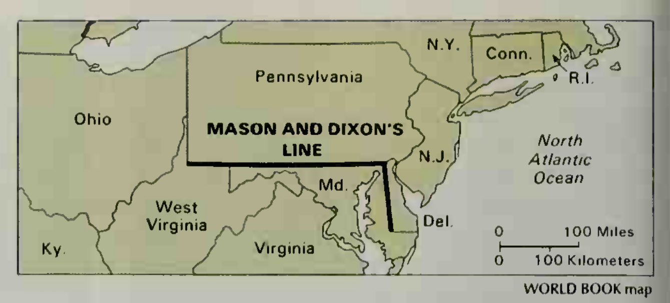
lowed the importation of slaves to go on until 1808. He was one of the few Southerners who opposed slavery. He felt slaves should be educated and gradually freed.

Mason also had other concerns. He opposed concentrating executive power in one person—the President—without an advisory council appointed by the House of Representatives. He feared that the Senate might develop into an aristocratic institution that would dominate the government. He was concerned that the economic interests of the South might be damaged if laws regulating commerce could be passed by a simple majority in each house of Congress. Mason also wanted a bill of rights to protect personal liberties against possible interference by the federal government.

Mason was dissatisfied because his fellow delegates did not meet these concerns, and he refused to sign the Constitution. When the Constitution was submitted to the states for ratification, he opposed it, and made the absence of a bill of rights his main objection. The Bill of Rights was finally added in 1791.

Early life. Mason was born in Fairfax County, Virginia, where his family had extensive landholdings. He studied law, managed his plantation, and was active in community affairs. His paper *Extracts from the Virginia Charters* (1773) formed a basis for U.S. claims to land south of the Great Lakes.

Mason preferred private life and refused many public offices. Finally, he became a member of the second Virginia Convention in Richmond in 1775. He also attended the third Virginia Convention in Williamsburg in 1776, where he wrote the Declaration of Rights and a large part of the state Constitution. Jack N. Rakove



Mason, James Murray (1798-1871), served as Confederate commissioner to Britain during the American Civil War (1861-1865). As commissioner, he became a key figure in a naval incident called the Trent Affair.

In 1861, Commissioner Mason sailed for Europe aboard a British ship, the *Trent.* His primary mission was to gain British aid for the South. While at sea, a Union warship stopped the *Trent* and seized Mason and John Slidell, the Confederate commissioner to France. This action resulted in a diplomatic crisis that nearly caused Britain to declare war on the Union. The crisis passed after Mason and Slidell were released in 1862. Mason went on to London but failed to win aid for the South.

Mason was born in what is now Washington, D.C. He represented Virginia in the U.S. House of Representatives from 1837 to 1839 and in the Senate from 1847 to 1861. Mason's grandfather George Mason wrote the Virginia Declaration of Rights of 1776, which formed the basis for the U.S. Bill of Rights. Michael Perman

See also **Mason, George; Slidell, John; Trent Affair.**

Mason, Lowell (1792-1872), was an influential American music educator and composer of hymn tunes. He wrote over 1,650 religious compositions and published many popular works, including hymn collections and books on music and music education. His best-known compositions include "Nearer My God to Thee" and "From Greenland's Icy Mountains." Mason was the first music teacher in American public schools, and became superintendent of music for Boston public schools in 1838. He founded the Boston Academy of Music with George J. Webb in 1833. Mason was born in Medfield, Mass. See also **America** (hymn). Leonard W. Van Camp

WORLD BOOK map

Location of Mason and Dixon's Line

Mason and Dixon's Line is usually thought of as the line that divides the North and the South. Actually it is the east-west boundary line that separates Pennsylvania from Maryland and part of West Virginia, and the north-south boundary between Maryland and Delaware. Before the Civil War, the southern boundary of Pennsylvania was considered the dividing line between the slave and nonslave states.

In the 1700's, a boundary quarrel arose between Pennsylvania and Maryland. The two agreed to settle the dispute by having the land surveyed. In 1763, they called in two English astronomers, Charles Mason and Jeremiah Dixon. They completed their survey in 1767. The line was named after them.

The surveyors set up milestones to mark the boundary. Through the years, souvenir hunters removed many stones and used them as doorsteps and curbstones. However, authorities recovered many of these stones and replaced nearly all the stolen markers. Occasionally a dispute arose as to the exact location of the line. But surveys made in 1849 and 1900 showed there was no important error in the line Mason and Dixon decided upon. A survey during the 1960's resulted in a slight shift of the line, which is now at 39°43'19.521" north latitude. Ray Allen Billington

Mason and Slidell. See **Mason, James Murray; Slidell, John.**

Masonry, also called Freemasonry, is the name of one of the oldest and largest fraternal organizations in the world. The organization's official name is Free and Accepted Masons. Masonry is dedicated to the ideals of charity, equality, morality, and service to God. Masons donate millions of dollars each year to charitable projects, including hospitals; homes for widows, orphans, and the aged; relief for people in distress; and scholarships. The organization has millions of members worldwide, including more than $2\frac{1}{2}$ million in the United States.

Symbols and rituals are an important part of Masonry. At times, some Masons dress in elaborate, colorful costumes and take part in dramatic ceremonies, many of which are kept secret from all except members. Most masonic symbols and rituals are based on the tools and practices of the building professions. Masons call God the "Great Architect of the Universe."

Masons try to promote "morality in which all men agree, that is, to be good men and true." Throughout its history, Masonry has sought to bring together men of different religious beliefs and political opinions. Men of any religion who profess belief in one God may join. Historically, however, most Masons have been Protestants. During much of its history, Masonry normally did

not admit Roman Catholics as members, in part because the Catholic Church prohibited Catholics from becoming Masons.

The lodges and degrees of Masonry. Men who wish to become Masons must apply for membership. They are not invited to join. Most of these individuals apply through a friend who is already a member. After a man has been accepted by the Masons, he joins a *Blue Lodge,* the basic organization of Masonry. Members of Blue Lodges may hold three degrees. When they join, they automatically receive the *Entered Apprentice* degree. Later, they may earn the second degree, called *Fellowcraft,* and the third degree, called *Master Mason.* To earn each degree, a Mason must learn certain lessons and participate in a ceremony that illustrates them. After a Mason acquires the third degree in a Blue Lodge, he may be invited to join either or both of the two branches of advanced Masonry—the *Scottish Rite* and the *York Rite.* He may receive further degrees as a member of these branches.

If a Mason enters the Scottish Rite, he may advance through 29 degrees that are designated both by names and numbers. The first degree in the Scottish Rite is the fourth degree in Masonry. The highest degree in the Scottish Rite is the 33rd, an honorary degree that members receive in recognition of outstanding service to Masonry, the community, or the nation. This degree is commonly called *Sovereign Grand Inspector General.*

If a Mason chooses to advance in the York Rite, the first four degrees he receives are called *Degrees of the Chapter.* The next three degrees make up the *Degrees of the Council.* In some U.S. states, members of the York Rite do not have to receive the Degrees of the Council in order to go on to higher degrees in the rite. The three highest degrees make up the *Orders of the Commandery.* The highest degree in the York Rite is that of *Knight Templar.*

The names *Scottish Rite* and *York Rite* are symbols of early times in Masonry. The earliest traditions are associated with Scotland and the city of York, England.

Organization. In most countries, all the Blue Lodges are governed by a National Grand Lodge headed by a Grand Master. But neither the United States nor Canada has a National Grand Lodge. Instead, each state or province has its own Grand Lodge and Grand Master.

More than a hundred fraternal organizations have a relationship with Masonry, but they do not form part of its basic structure. One of the best known is the *Order of the Eastern Star,* an organization for women relatives of Masons who have achieved at least the degree of Master Mason. The Masons and the Order of the Eastern Star also sponsor organizations for boys and girls. Boys may join the *Order of DeMolay.* Girls may become members of *Job's Daughters* in some U.S. states and *Rainbow for Girls* in others.

The *Ancient Arabic Order of Nobles of the Mystic Shrine* admits members who are at least 32nd degree Masons in the Scottish Rite or Knights Templar in the York Rite. There are three Shrine-associated organizations for wives and some female relatives of Shrine members. They are the *Ladies Oriental Shrine of North America, Daughters of the Nile,* and *Imperial Council Shrine Guilds of America, Inc.*

Prince Hall Freemasonry is a separate masonic organization for men. Almost all of its 275,000 members are black Americans. Nearly all other Masons are white. Prince Hall Masons are devoted to the same ideals as other Masons. In addition, the structure of the organization of Prince Hall Freemasonry resembles that of the principal Masonry group. For example, in each state with Prince Hall lodges, one Grand Master heads all lodges in the state. Prince Hall members also earn degrees that are similar to those earned by other Masons. However, many white Masons claim that Prince Hall Freemasonry is not a true Masonic organization.

Oil painting on canvas by Stanley Massey Arthurs; Acacia Mutual Life Insurance Co., Washington, D.C.

George Washington, wearing his regalia as a member of the Masons, laid the cornerstone of the United States Capitol in Washington, D.C., in 1793. The historic ceremony took place under the sponsorship of the Grand Lodge of Maryland.

History. Many of the ideas and rituals of Masonry originated in the period of cathedral building from the 900's to the 1600's. At that time, stonemasons formed associations called *guilds* in various European cities and towns. With the decline of cathedral building in the 1600's, many masons' organizations became social societies. They began accepting members who had never been stoneworkers and called these men *speculative masons.*

In the early 1700's, speculative masons created the complicated masonic system of rituals and symbols that is still in use today. The system is based on stonemason traditions and on ideas developed during the Age of Reason (see **Age of Reason**).

In 1717, four fraternal lodges, which originally may have been masons' organizations, united under the Grand Lodge of England. The Masons of today consider the formation of the Grand Lodge of England to be the beginning of their organized society. The order spread quickly to other lands and included such famous men as the American statesman Benjamin Franklin, King Frederick II of Prussia, the Austrian composer Wolfgang Amadeus Mozart, U.S. President George Washington, and the French philosopher Voltaire.

British colonists brought Masonry to North America, where it developed into two separate organizations, one

for whites and one for blacks. White Masonry was popular in the early 1800's. But its involvement in politics and its secrecy contributed to an antimasonic movement in the late 1820's and early 1830's. This movement almost destroyed the organization. White Masonry regained its popularity by the mid-1860's. By the 1880's, it had become a highly respected organization whose members included prominent businessmen, ministers, and politicians. During the 1900's, white Masonry became one of the world's largest fraternal organizations.

The organization for blacks, Prince Hall Freemasonry, was founded by Prince Hall, a free black Methodist minister who settled in the Boston area in 1765. White American Masons had refused to admit blacks into their lodges. But in 1775, a British Army lodge admitted Hall and 14 other free blacks. Soon these 15 men formed African Lodge 1, but white American Masons refused to grant the lodge a charter. It received its charter, as African Lodge 459, in 1787 from the Grand Lodge of England. In 1791, the American Prince Hall Grand Lodge was established. Before the Civil War (1861-1865), this lodge spread mainly throughout the U.S. states in which slavery was illegal. After the war, the lodge expanded into the South.

Prince Hall and other early black Masons protested slavery and sought to improve the status of free blacks. More recently, many Prince Hall lodges have taken part in the U.S. civil rights movement. Prince Hall members have included the historian and sociologist W. E. B. DuBois and Thurgood Marshall, the first black justice of the U.S. Supreme Court. Lynn Dumenil

Masqat. See Muscat.

Masque, *mask* or *mahsk,* was an elaborate form of entertainment presented at European courts. The masque reached its height in England during the early 1600's. English masques combined dancing, drama, music, and poetry with lavish sets and costumes, often to convey a moral message. Masques were presented as part of banquets to honor visiting royalty or to celebrate such events as a coronation, holiday, or wedding.

The English architect Inigo Jones was the most gifted designer of English masques. Beginning in 1605, he collaborated in the production of masques with the English poet and playwright Ben Jonson. Many of their works opened with an *antimasque*—that is, an *allegory* (symbolic story) in song, dance, and poetry involving grotesque and comic characters. The masque followed, portraying in allegory the triumph of the forces of good and virtue—roles often acted and danced by the royal hosts and their courtiers. At the close, actors danced with partners from the audience. Albert Wertheim

See also **Drama** (picture: Masques).

Mass is often defined as the amount of matter in an object. But physicists define mass as a measure of *inertia,* a property of all matter. Due to inertia, a motionless object tends to remain motionless. A moving object tends to continue to move at a *constant velocity*—that is, at a constant speed and in the same direction.

The greater an object's mass, the greater the force needed to change its velocity by a given quantity in a given amount of time. An example of such a change would be an increase in velocity from 15 meters per second northward to 20 meters per second northward in 10 seconds.

Scientists refer to a change in velocity as an *acceleration.* The relationship between force, mass, and acceleration is described by *Newton's second law of motion,* which was discovered by English scientist Isaac Newton in the mid-1660's and published in 1687. This law can be expressed as $F = ma$, where F is force, m is mass, and a is acceleration.

In the International System of Units (SI), the modern metric system, force can be given in newtons, mass in kilograms, and acceleration in meters per second per second. Suppose we apply a force of 1 newton to an object with a mass of 1 kilogram under the following four conditions: (1) the object is already moving northward at a rate of 15 meters per second, (2) we apply the force in the direction of motion, (3) no other force is being applied to the object, and (4) there is no frictional force resisting the applied force. Each second we apply the force, the velocity of the object will increase by 1 meter per second. Thus, in 5 seconds, the object will be moving northward at a rate of 20 meters per second.

But suppose the object has a mass of 2 kilograms and we still want to increase its velocity by 1 meter per second each second. We must apply a force of 2 newtons to achieve this acceleration.

In the inch-pound system of units customarily used in the United States, there are two units of mass. In commercial and everyday use, people use the pound, which equals 0.454 kilogram. Engineers prefer to use the slug, equal to 14.594 kilograms, for mass and the pound for force. A force of 1 pound will accelerate an object with a mass of 1 slug by 1 foot per second each second.

Mass and weight. In commercial and everyday use, *weight* is understood to mean *mass.* In this sense, *to weigh* means *to determine the mass of.* For example, a man weighs himself to determine the amount of matter that makes up his body. In a country using the metric system, the weighing scale would display the man's weight in kilograms. In the United States, the display would be in pounds.

In science and technology, *weight* refers to the gravitational force on an object. According to Newton's law of gravitation, which was also published in 1687, weight is proportional to mass. This law is represented by $W = mg$ where W is weight, m is mass, and g is the acceleration due to gravity.

On the surface of the earth, g is about 9.8 meters per second per second in the SI and about 32 feet per second per second in the inch-pound system. Thus, the gravitational force on a 1-kilogram object is about 9.8 newtons. The force on a 1-slug object is about 32 pounds. Michael Dine

Mass is the name used by several Christian churches for the celebration of the sacrament of the Eucharist, or Lord's Supper. In this important ritual, the worshiping

community gathers to give thanks and praise to God and to participate in the ongoing mystery of the death and Resurrection of Jesus Christ. This celebration is called the Mass by Roman Catholics, and by some Episcopal and Lutheran churches. The Eastern Orthodox service known as the *Divine Liturgy* is similar to the Mass. Other Christians celebrate it in similar rituals.

The Mass has two major parts. The first part is a service that includes readings from Scripture and a sermon. The second part is a Eucharistic rite of prayer focusing on a remembrance of the Last Supper, the basis of the sacrament of Holy Communion (see **Communion**). Worshipers sing hymns and say prayers during the Mass.

The Eucharist was instituted by Jesus, who shared bread and wine with His disciples at the Last Supper. Most Christians believe that Jesus intended His words and actions during the Last Supper to be continued in a sacramental ritual. They base their belief upon accounts of the Last Supper in the Gospels and 1 Corinthians in the New Testament.

The word *Mass* comes from the Latin word *mittere*, meaning "to send." People who had gathered to celebrate the Lord's Supper or the "breaking of the bread" were then sent forth to practice what they had celebrated. Richard L. Schebera

Mass number. See **Atom** (The mass number).

Mass production is the production of machinery and other articles in standard sizes in large numbers. Mass production makes it possible to manufacture things faster, and often at less cost. It also means that a replacement can be obtained for any part of a manufacturing machine or other product that breaks down.

Mass production began in 1800, when the United States was building up its army. Until that time, gunsmiths started a second gun only after they had completed the first one. Thus, each gun was a little different.

In 1798, the government hired the inventor Eli Whitney to make 10,000 muskets in two years. By 1800, Whitney had delivered only 500. He was called to Washington to explain the delay.

In front of a board of experts, Whitney placed 10 musket barrels, 10 stocks, 10 triggers, and so on, in separate piles. Then he assembled 10 muskets from the pieces, showing that anyone could do this if the parts were identical. In this way, Whitney demonstrated the basis of mass production—the interchangeability of parts. He had spent about two years developing *machine tools* that made identical parts.

In 1918, five engineering societies established what is now the American National Standards Institute, Inc. The institute studies and sets up standards of quality and methods of interchangeability for mass-produced parts in most U.S. industries.

In the early 1900's, Henry Ford originated the moving assembly line for manufacturing automobiles. After the automobile parts are made, the automobile frame is attached to a conveyor belt. This belt consists of a chain that moves along the floor of the factory. Workers are stationed along the chain in an assembly line. As the car moves slowly along the line, each worker does a special task. The task must be done in a certain length of time, and with exactness, because the work of the entire line is stopped if it is necessary to halt the moving chain. Mass production led to the *division-of-labor* system, in which each worker is skilled in a single operation. See **Assembly line; Conveyor belt.** Marvin F. DeVries

Mass spectroscopy, *spehk TRAHS kuh pee,* also called *mass spectrometry,* is a method of separating ionized atoms or molecules according to their mass (m) and electric charge (z). It involves the use of an instrument called a *mass spectrometer.* Mass spectroscopy provides an effective means of identifying elements, isotopes, and molecules. It can also be used to determine the chemical composition and structure of more complex substances.

In a basic mass spectrometer, a sample of a substance is placed in a vacuum. Electrons bombard the sample, forming ions. An electric field forces a stream of ions away from the sample and separates them according to the strength of their charges. Each group of ions then passes through a magnetic field. This field deflects lighter ions more than heavier ions, producing a pattern called a *mass spectrum.* This pattern has peaks that correspond to the *m/z values* of each type of ion in the sample. An *m/z* value is the ratio of the mass of an ion to the ion's charge. The mass spectrum is scanned by varying the intensity of the magnetic field. Each *m/z* value is recorded by an electrical detector.

Most mass spectrometers are combined with a computer, which stores, manipulates, and interprets the data. A mass spectrometer also can be combined with such separating devices as *gas chromatographs* and *liquid chromatographs* to analyze mixtures made up of hundreds of components (see **Chromatography**).

Mass spectroscopy has many important uses in science and industry. Common uses include distinguishing one isotope from another, measuring atomic and molecular masses, and detecting impurities in silicon, which is used in transistors and other electronic devices. Government regulatory agencies sometimes use mass spectroscopy to detect—and measure the amounts of—pollutants in water, soil, and other substances.

Margaret E. Wickham St. Germain

WORLD BOOK diagram

In a basic mass spectrometer, electrons bombard a gas sample to form ions. A magnetic field deflects the lighter ions more than the heavier ones. By varying the field's intensity, each of the deflected ions is exposed in rapid succession to a detector that measures the ion's mass and charge.

©Steve Dunwell

Autumn colors frame a colonial church in Brimfield, located in south-central Massachusetts. The state's natural beauty and its many historic landmarks make it one of the main tourist attractions in the United States. About 23 million people visit Massachusetts each year.

Massachusetts *The Bay State*

Massachusetts is the sixth smallest state of the United States, but it stands among the leaders in many fields. Only New Jersey, Hawaii, Connecticut, Delaware, and Rhode Island have smaller areas. Massachusetts ranks third among the most densely populated states, behind New Jersey and Rhode Island. Boston, the state's capital and largest city, is a major U.S. seaport and air terminal. It is New England's major center of finance and trade. Universities in and around Boston help make the area one of the world's great cultural, educational, medical, and research centers. Historic landmarks make Massachusetts one of America's main tourist spots.

The land in Massachusetts is a series of hills and valleys. From sea level near the Atlantic Ocean, the state reaches a height of about 3,500 feet (1,100 meters) near its western border. The best farmland lies in the river valleys and near the coastline. Massachusetts produces more cranberries than any other state. Boston, Gloucester, and New Bedford are important fishing ports and centers for the canning and processing of fish.

The Norse explorer Leif Ericson may have visited the Massachusetts region about the year 1000. He was one of the first Europeans to sail to North America. In 1620, the Pilgrims settled at what is now Plymouth. The Puritans came in 1630. Both these groups left England in search of better economic opportunities and freedom to pursue their religious beliefs. The first newspaper, printing press, and library in the British colonies were established in Massachusetts. The first college, Harvard, was founded at Cambridge in 1636. Boston Latin School, the first secondary school in the colonies, opened in 1635. The first public high school in the United States, Boston English High School, opened in 1821.

Many of the events that led up to the Revolutionary War took place in Massachusetts. These included the Boston Massacre in 1770 and the Boston Tea Party in

The contributors for this article are Winfred E. A. Bernhard, Professor of Early American History at the University of Massachusetts at Amherst; Michael G. Mensoian, Professor of Geography and Director of Armenian Studies at the University of Massachusetts at Boston; and Robert L. Turner, Chief Editorial Writer of The Boston Globe.

Interesting facts about Massschusetts

Volleyball was developed by William Morgan in 1895. Morgan was a director of the YMCA in Holyoke.

The National Woman's Rights Convention was held in Worcester on Oct. 23 and 24, 1850. It was the first national convention of women in favor of woman's suffrage.

National Woman's Rights Convention

The oldest voluntary military organization in the world, the Ancient and Honorable Artillery Company, was established in Boston in 1838. Its purpose was to help men improve their military skills.

The first post office in the American Colonies was established at the tavern of Richard Fairbanks in Boston in 1639. The Massachusetts Bay Colony gave Fairbanks the right to process mail sent to or delivered from England.

WORLD BOOK illustrations by Kevin Chadwick

First World Series

The first World Series in baseball history was played in Boston from Oct. 1 to Oct. 13, 1903. The Boston Pilgrims beat the Pittsburgh Pirates in the series, five games to three.

Basketball was invented in Springfield in 1891 by James A. Naismith, a physical-education instructor at the School for Christian Workers (now Springfield College). He invented the game to create a team sport that could be played indoors in winter.

Jeff Gnass, West Stock

Fishing boats dock at Provincetown Harbor on Cape Cod. Many fine harbors line the coast of Massachusetts, helping to make it one of the leading commercial fishing states.

1773. On the night of April 18, 1775, Paul Revere made his famous ride to warn his fellow patriots that British troops were coming. On April 19, 1775, minutemen at Lexington and then at Concord fought the first battles of the Revolutionary War. On Feb. 6, 1788, Massachusetts ratified the U.S. Constitution, becoming the sixth state to join the Union.

Four U.S. presidents were born in Massachusetts. John Adams, the second president, and his son, John Quincy Adams, the sixth president, were both born in Braintree (now Quincy). John F. Kennedy, the 35th president, was born in Brookline. George H. W. Bush, the 41st president, was born in Milton.

Massachusetts gets its name from the Massachusett Indian tribe, which lived in the region when the Pilgrims arrived. The name probably means *near the great hill,* or *the place of the great hill.* Historians believe it refers to the Great Blue Hill south of Boston. Massachusetts is often called the *Bay State* because the Puritans founded their colony on Massachusetts Bay. Massachusetts is one of four states officially called *commonwealths.* The others are Kentucky, Pennsylvania, and Virginia.

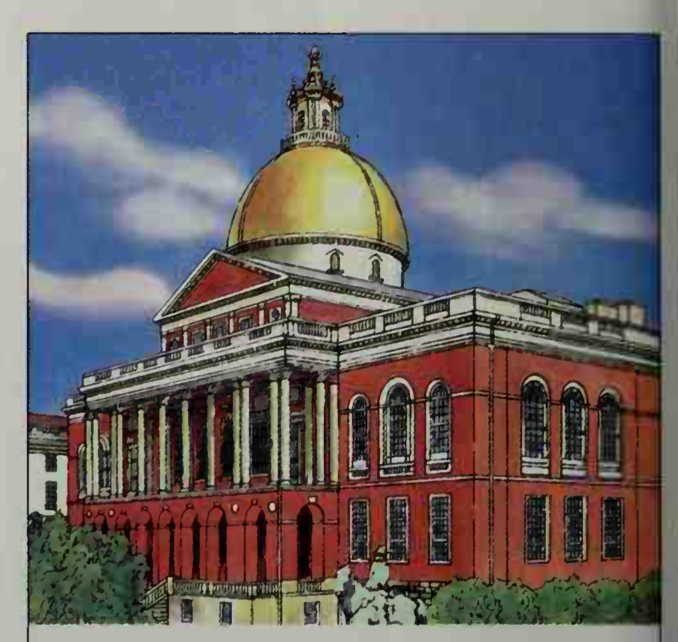
Cy Furlan

The Faneuil Hall Marketplace in downtown Boston attracts thousands of people each day. The marketplace, developed in 1976, has more than 150 shops, food stalls, restaurants, and bars.

Massachusetts in brief

Symbols of Massachusetts

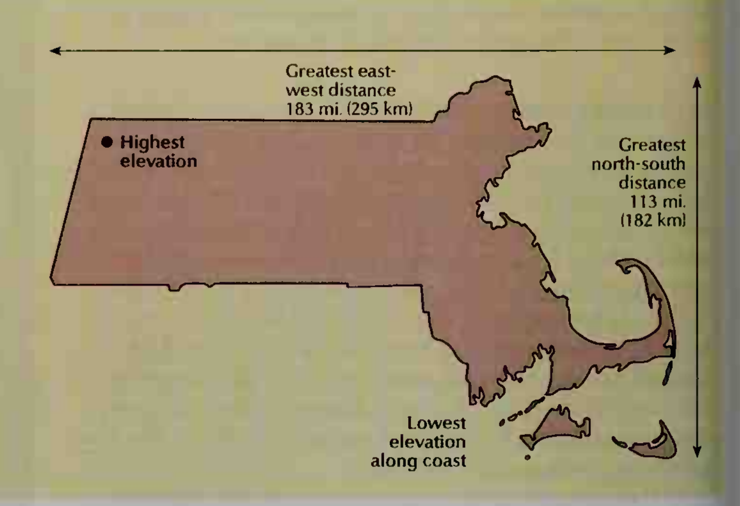
The state flag, adopted in 1971, bears a shield with the figure of an Indian. The Indian has been a symbol of Massachusetts since 1629. The star represents Massachusetts as one of the original 13 Colonies. A crest above the shield, an arm wielding a sword, coincides with the motto. The state seal, adopted in 1885, bears the same symbols as the flag.



State flag

State seal

Massachusetts (brown) ranks 45th in size of all the states and 4th in size among the New England States (yellow).



The State House is in Boston, the capital of Massachusetts since 1630.

General information

Statehood: Feb. 6, 1788, the sixth state.
State abbreviations: Mass. (traditional); MA (postal).
State motto: *Ense petit placidam sub libertate quietem* (By the Sword We Seek Peace, but Peace Only Under Liberty).
State song: "All Hail to Massachusetts" by Arthur J. Marsh.

Land and Climate

Area: 8,262 sq. mi. (21,398 km²), including 424 sq. mi. (1,098 km²) of inland water but excluding 979 sq. mi. (2,536 km²) of Atlantic coastal water.
Elevation: *Highest*—Mount Greylock, 3,491 ft. (1,064 m) above sea level. *Lowest*—sea level along the Atlantic Ocean.
Coastline: 192 mi. (309 km).
Record high temperature: 107 °F (42 °C) at New Bedford and Chester on Aug. 2, 1975.
Record low temperature: −35 °F (−37 °C) at Chester on Jan. 12, 1981.
Average July temperature: 71 °F (22 °C).
Average January temperature: 25 °F (−4 °C).
Average yearly precipitation: 45 in. (114 cm).

Important dates

- **1620** The Pilgrims landed at Plymouth.
- **1630** The Puritans founded Boston.
- **1636** Harvard became the first college in the colonies.
- **1773** Patriots dumped British tea into Boston Harbor during the Boston Tea Party.
- **1775** The American Revolutionary War began at Lexington and Concord.

For information on the economy, write to: Office of Business Development, 10 Park Plaza, Suite 3720, Boston, MA 02116.

The state's official Web site at www.state.ma.us also provides a gateway to much information on Massachusetts's economy, government, and history.

1788 Massachusetts became the sixth state on February 6.

1807 The Embargo Act ruined Massachusetts shipping and led to the rise of manufacturing.

1831 William Lloyd Garrison began publishing his antislavery newspaper *The Liberator* in Boston.

1971 Massachusetts began a major reorganization of its state government.

1988 Massachusetts celebrated its statehood bicentennial.

People

Population. The 2000 United States census reported that Massachusetts had 6,349,097 people. The population had increased 5 $\frac{1}{2}$ percent over the 1990 figure, 6,016,425. According to the 2000 census, Massachusetts ranks 13th in population among the 50 states.

About 94 percent of the people of Massachusetts live within one of the metropolitan statistical areas that are entirely or partly in the state (see **Metropolitan area**). These areas are Barnstable-Yarmouth, Boston, Brockton, Fitchburg-Leominster, Lawrence, Lowell, New Bedford, Pittsfield, Providence (Rhode Island)-Fall River-Warwick, Springfield, and Worcester. For the populations of these areas, see the *Index* to the political map of Massachusetts.

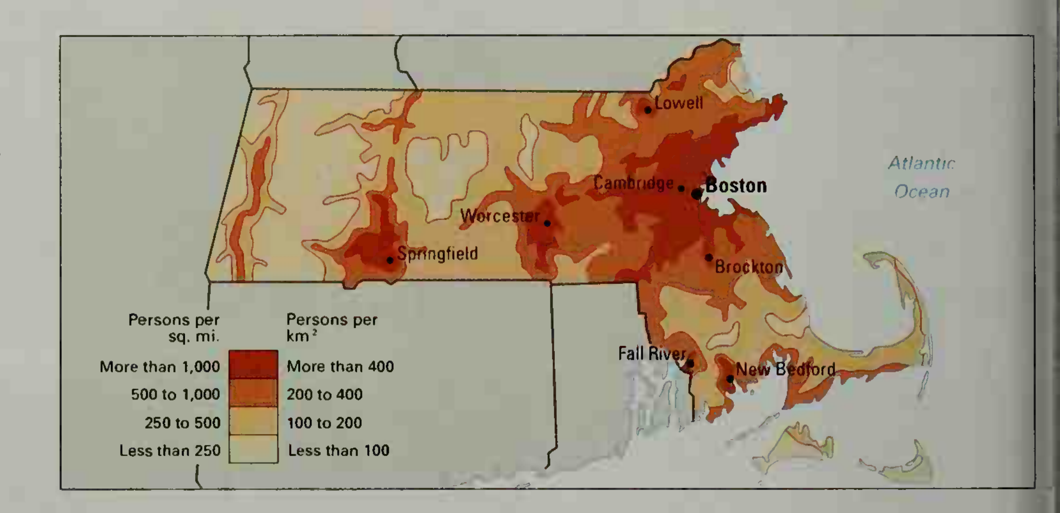
Boston is the state's largest city and the capital of Massachusetts. Other large cities in Massachusetts, in order of population, are Worcester, Springfield, Lowell, Cambridge, Brockton, and New Bedford.

About 88 percent of the people living in Massachusetts were born in the United States. The largest groups of people born in other countries came from Canada, Italy, and the United Kingdom. The state's largest population groups include people of Irish, English, Italian, and French descent. About 7 percent of the state's people are Hispanic Americans. African Americans make up about 5 percent, and Asians account for about 4 percent.

Schools. The Puritans of Boston built the first school in Massachusetts in 1635. This school, the Boston Latin School, was the first secondary school in the American Colonies. In 1647, the Massachusetts Bay Colony ordered that elementary schools be established in all towns where there were 50 or more families. This action marked the first time that any government in the world provided free public education at public expense. In 1852, Massachusetts became the first state to require its children to attend school.

The state Department of Education supervises public education from prekindergarten through secondary school, as well as vocational and adult basic education. The department has a commissioner, a deputy commissioner, and a nine-member Board of Education. Children from ages 6 through 15 must attend school. For the number of students and teachers in Massachusetts, see **Education** (table).

Massachusetts has some of the nation's most highly regarded *prep schools* (private schools that prepare students for college). The state's universities and colleges are highly acclaimed.



Libraries. The first library in the American Colonies was established in Massachusetts in 1638, when John Harvard gave his collection of books to Harvard College. Harvard's library is now the largest university library in the world. It has more than 13 million volumes. Today, Massachusetts has over 450 public libraries.

Several Boston libraries own outstanding collections. These libraries include the Athenaeum, which has George Washington's collection of books; the John F. Kennedy Library; the Massachusetts Historical Society; the State Library, in the State House; and the Boston Public Library.

Other Massachusetts libraries with important collections include the Essex Institute in Salem and the American Antiquarian Society in Worcester. The Harvard library owns collections of rare books and old Indian manuscripts.

Population density

About half the people of Massachusetts live in the Boston metropolitan area. Mountainous regions in the west are among the most thinly populated parts of the state.

WORLD BOOK map; based on U.S. Census Bureau data.

The Boston Athenaeum is a small but well-known private library. The Athenaeum has many rare volumes, including a collection of books originally owned by George Washington.

© Steve Dunwell

Harvard University, in Cambridge, is the oldest institution of higher learning in the United States. The university was founded in 1636. The Charles River flows near the campus.

Museums. The Museum of Fine Arts in Boston owns one of the nation's largest collections of artwork. The Isabella Stewart Gardner Museum in Boston has many outstanding Renaissance paintings. Boston's Children's Museum is one of the oldest and largest in the nation. The George Walter Vincent Smith Art Museum in Springfield, the Worcester Art Museum, and the Sterling and Francine Clark Art Institute in Williamstown are among the nation's best-known smaller museums. The Massachusetts Museum of Contemporary Art in North Adams displays many works too large to fit in traditional museums. Other museums include the Museum of Science in Boston, the New Bedford Whaling Museum, the Peabody Essex Museum of Salem, the Norman Rockwell Museum in Stockbridge, and the John Woodman Higgins Armory Museum in Worcester.

*Does not appear on map; key shows general location.
†Census designated place—unincorporated, but recognized as a significant settled community by the U.S. Census Bureau.
▲Population is for entire town (township), including rural areas.
°County seat.
Places without population figures are unincorporated.
Source: 2000 census.

Court Square is a popular park in downtown Springfield. The Soldiers Monument, *center,* stands in the square, honoring men from Massachusetts who fought in the Civil War.

Visitor's guide

Skiing brings many visitors to the Berkshire Hills and to other parts of Massachusetts. The Atlantic Ocean and many lakes and rivers attract swimmers, fishing enthusiasts, and boaters. But Massachusetts offers perhaps its greatest rewards to the student of American history. Historic sites date back to the Pilgrims, to colonial witchcraft trials, and to the Revolutionary War in America.

One of the outstanding yearly events in Massachusetts is the Tanglewood Music Festival, held in the Tanglewood Music Shed near Lenox. This 210-acre (85-hectare) estate in the Berkshires is the summer home of the Boston Symphony Orchestra.

Places to visit

Following are brief descriptions of some of Massachusetts' many interesting places to visit:

Basketball Hall of Fame, in Springfield, honors outstanding basketball players and features exhibits on the history of the game.

Bearskin Neck, in Rockport, is a long stretch of restored cottages in a former fishing village. The cottages now house craft shops, restaurants, and galleries. A restored fishing shanty near the end of Bearskin Neck is a popular subject for painters and photographers.

Black Heritage Trail winds along Beacon Hill's north slope, a neighborhood where black Bostonians of the 1800's lived. The trail has nine sites, including a *station* (hiding place) on the *underground railroad,* which aided slaves fleeing to the free states or to Canada.

Boston is a major cultural center and one of the nation's great historic cities. The city became known as the *Cradle of Liberty* when it led the American colonies in their struggle for independence. Visitors may follow the Freedom Trail, a 3-mile- (5-kilometer-) long red line along the city's sidewalks and connects 16 historic sites. See **Boston** (Downtown Boston; illustration: Boston's Freedom Trail).

Cape Cod, a peninsula in southeastern Massachusetts, is a famous summer resort and vacation area. The peninsula faces Cape Cod Bay on the north, Nantucket Sound on the south, and the Atlantic Ocean on the east. Long sandy beaches stretch along the cape.

Harvard University, in Cambridge, is one of the world's most famous universities. Harvard was founded in 1636. It is the oldest institution of higher learning in the United States. Harvard Yard, the center of the original college, still retains much of its early charm. Notable libraries and museums on the campus include Widener Library and the Fogg Art Museum.

Martha's Vineyard, an island 4 miles (6 kilometers) off the southeastern coast of Massachusetts, is a popular resort area. It features long stretches of unspoiled beaches and forests.

Nantucket Island, 30 miles (48 kilometers) from Cape Cod, is a former whaling port that is now an important resort center. Beaches and moors cover much of the island.

Old Sturbridge Village, in Sturbridge, is a re-creation of a typical New England town of the 1830's.

Plimoth Plantation, in Plymouth, is a re-creation of a 1627 Pilgrim village. *Mayflower II,* built the way the original *Mayflower* is thought to have looked, is maintained by the plantation in the nearby downtown area.

Salem has attractions that include the birthplace of American author Nathaniel Hawthorne and Witch House, the home of a judge of the witchcraft trials of 1692.

U.S.S. *Constitution,* also called *Old Ironsides,* is docked at the Charlestown Navy Yard in Boston. This early U.S. Navy frigate became famous during the War of 1812. Oliver Wendell Holmes honored the ship with his famous poem "Old Ironsides."

Walden Pond, near Concord, has become a symbol of nature. The American writer Henry David Thoreau built a simple cabin on its shore and lived there for two years. His book *Walden* describes his experiences at the pond and his views on nature and life.

National historical parks, seashores, and historic sites. Minute Man National Historical Park is located between Lexington and Concord. Cape Cod National Seashore includes beaches, marshes, and woodland areas on outer Cape Cod. Saugus Iron Works National Historic Site in Saugus is a reconstruction of the first successful ironworks in North America. Massachusetts has several other national historic sites. For information on these areas, see the map and tables in the article on **National Park System**.

State parks and forests. Massachusetts has 107 state parks, forests, and recreational areas. For information, write to Massachusetts Department of Environmental Management, Division of Forests and Parks, 100 Cambridge Street, 19th Floor, Boston, MA 02202.

Annual events

January-March
Bay State Games in Adams, North Adams, and Williamstown (last weekend in January); Jimmy Fund "Salute to Winter" Festival Weekend in Holyoke (February); New England Spring Flower Show in Boston (March); St. Patrick's Day Parade in Boston (March); Spring Bulb Show in Northampton (March).

April-June
Daffodil Festival on Nantucket Island (April); Whale Watch Cruises from Cape Ann to Cape Cod (April-October); Reenactment of Paul Revere's Ride in Boston (third Monday in April); Reenactment of the Battle of Lexington and Concord in Lexington (third Monday in April); Boston Marathon (third Monday in April); Seaport Festival in Salem (May); Antique Automobile Show in Stockbridge (May); ACC CraftFair in West Springfield (June); Bunker Hill Day Weekend in Boston (June); Hyannis Harbor Festival in Hyannis Harbor (June); Blessing of the Fishing Fleets in Provincetown (June); Esplanade Concerts in Boston (June-August); Williamstown Theatre Festival (June-August); Tanglewood Music Festival in Lenox (June-September).

July-September
Up-Country Hot Air Balloon Fair in Greenfield (July); Jacob's Pillow Dance Festival in Becket (July-August); Pilgrim Process Processional in Plymouth (Fridays, July-August); Sandcastle and Sculpture Day in Nantucket (August); Teddy Bear Rally in Amherst (August); "Big E" State Fair in West Springfield (September); World Kielbasa Festival in Chicopee (weekend after Labor Day); Cranberry Harvest Festival in Harwich (September); Apple-Peach Festival in Acushnet (mid-September).

October-December
Scallop Festival in Buzzards Bay (October); Rowing Regatta on the Charles River in Boston and Cambridge (October); Haunted Happenings in Salem (October); Chowder Contest on Martha's Vineyard (December); Norman Rockwell's Christmas on Main Street in Southbridge (December).

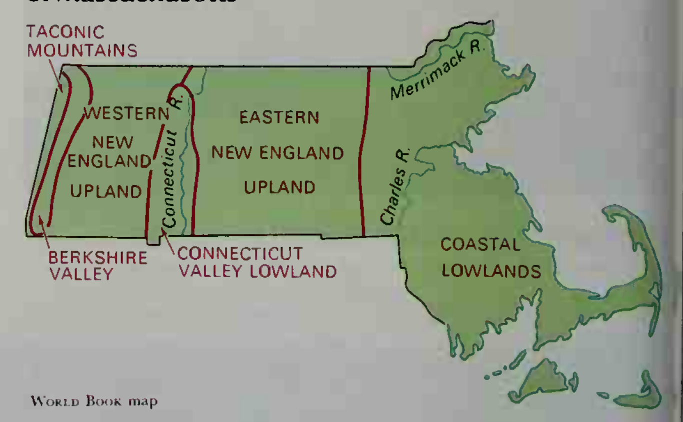
Land regions. Massachusetts has six main land regions. They are, from east to west: (1) the Coastal Lowlands, (2) the Eastern New England Upland, (3) the Connecticut Valley Lowland, (4) the Western New England Upland, (5) the Berkshire Valley, and (6) the Taconic Mountains.

The Coastal Lowlands are part of a large land region that extends over the entire New England coastline. The lowlands make up the eastern third of Massachusetts. They also include Nantucket Island, Martha's Vineyard, the Elizabeth Islands, and other smaller offshore islands. The region has many rounded hills, swamps, small lakes and ponds, and short shallow rivers. The lowlands are dotted with glacial deposits. These were left by glaciers thousands of years ago during the Ice Age. The Great Blue Hill, south of Boston, rises to a height of about 635 feet (194 meters). Several excellent harbors lie along the coast. They include Boston, Gloucester, and New Bedford.

The Eastern New England Upland makes up part of a land region that stretches from Maine to New Jersey. The upland is an extension of the White Mountains of New Hampshire. In Massachusetts the upland extends westward from the Coastal Lowlands for 40 to 60 miles (64 to 97 kilometers). The upland region rises to a height of about 1,000 feet (300 meters) and then gradually slopes downward toward the Connecticut Valley Lowland. Many streams cut through the Eastern New England Upland.

The Connecticut Valley Lowland is a long, sausage-shaped region. It extends from northern Massachusetts to southern Connecticut. In Massachusetts, the valley, which is 20 miles (32 kilometers) wide, is hemmed in by hills to the north, east, and west. The Connecticut River flows through the valley region. Rich soil and a mild climate provide good farming.

The Western New England Upland extends through Vermont, Massachusetts, and Connecticut. In Massachusetts, the region stretches 20 to 30 miles (32 to 48 kilometers) westward from the Connecticut Valley Lowland to the Berkshire Valley. The Berkshire Hills, a range that covers this region, is an extension of the Green Mountains of Vermont. In Massachusetts, the Western New England Upland region itself is often called the Berkshire Hills. The land rises from the Connecticut Valley to rugged, beautiful heights of more than 2,000 feet (610 meters). In this region is Majestic Mount Greylock, which rises 3,491 feet (1,064 meters) and is the highest point in Massachusetts. Farms and towns lie on the region's slopes.



The Berkshire Valley is a narrow path of lower land that extends into northern Connecticut. In Massachusetts, it winds between the Berkshire Hills and the Taconic Mountains. This valley region is less than 10 miles (16 kilometers) wide. Its many green meadows are good for dairy farming.

The Taconic Mountains extend into Vermont. This region skirts the extreme western edge of Massachusetts. At its widest point, the region measures no more than 6 miles (10 kilometers) across. The Taconic Range slopes from northwestern Massachusetts to the southwestern corner of the state, where Mount Everett rises 2,602 feet (793 meters).

Coastline of Massachusetts measures 192 miles (309 kilometers). If the coastline of each bay and inlet were added to the total, the state's coastline would measure more than 1,500 miles (2,410 kilometers). Boston is the state's most important harbor. Other important harbors include Gloucester in the north, Quincy and Weymouth in Boston Bay, and New Bedford and Fall River in the south.

Islands. The Elizabeth Islands, Martha's Vineyard, and Nantucket Island are the state's largest and most important islands. Together with Cape Cod, these islands form the boundaries of Nantucket Sound. Martha's Vineyard and Nantucket Island are important resort centers. A number of smaller islands also lie along the coast of Massachusetts.

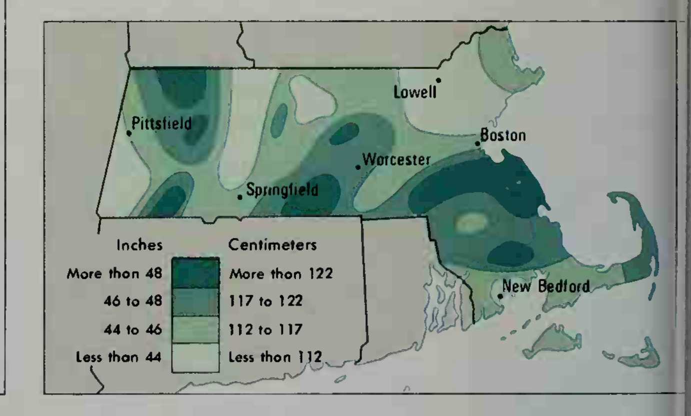
Rivers and lakes. Massachusetts has 4,230 miles (6,808 kilometers) of rivers. The Connecticut River is the state's most important waterway. It flows southward and provides water for the most fertile Massachusetts farmlands. The Connecticut's chief tributaries include the Deerfield and Westfield rivers to the west, and the Chicopee and Millers rivers to the east.

The far western part of Massachusetts has two important rivers—the Hoosic River and the Housatonic River. The Hoosic River flows northward and westward into Vermont, and finally drains into the Hudson River. The scenic Housatonic River flows southward into Connecticut. The Blackstone River drains Massachusetts' eastern upland region. It then flows southeastward into Rhode Island.

The Merrimack River is the most important river in the Coastal Lowlands. It enters the state from New Hampshire. Then the Merrimack turns abruptly northeastward and flows almost parallel to the Massachusetts border until it empties into the Atlantic Ocean at Newburyport. The Nashua and Concord rivers are the Merrimack's main tributaries. The Charles, Mystic, and Neponset rivers all empty into Boston Harbor. The Taunton River flows southward into Rhode Island's Mount Hope Bay.

Shostal



Mount Greylock, the highest point in Massachusetts, rises 3,491 feet (1,064 meters) in the state's Western New England Upland region. This area is often called the Berkshire Hills.

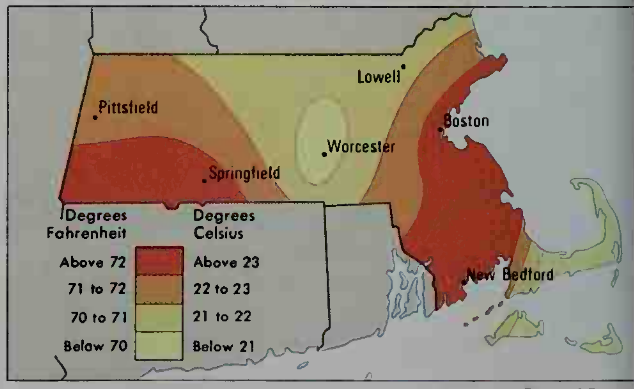
Average yearly precipitation

Amounts of precipitation are uneven throughout Massachusetts. In general, the east gets more precipitation than the west.



Average January temperatures

The eastern part of the state has the mildest wintertime temperatures. The winters are increasingly cold to the west.

Average July temperatures

Massachusetts has even summer temperatures. Only the area around Worcester averages below 70° F. (20° C.).

WORLD BOOK maps

Massachusetts has more than 1,300 lakes and ponds. More than a fourth of these lakes supply drinking water to nearby cities and towns. The state's two largest lakes—Quabbin and Wachusett—are artificially created reservoirs. Quabbin Reservoir, near Ware in the center of the state, is one of the nation's largest reservoirs of drinking water. It covers more than 39 square miles (101 square kilometers). Wachusett Reservoir, north of Worcester, covers 6 $\frac{1}{2}$ square miles (17 square kilometers). These reservoirs supply water to the Boston metropolitan area.

Many of the state's lakes have Indian names. For example, Lake Chaubunagungamaug, also called Lake Webster, received its name from the Nipmuc Indians. The long form for this name is Chargoggagoggmanchauggagoggchaubunagungamaug. The name means "You fish your side of the lake. I fish my side. Nobody fishes the middle."

Plant and animal life. Forests cover about three-fifths of the land area of Massachusetts. The most common softwood trees include the eastern white and red pines, the eastern hemlock, and the pitch pine. Common hardwoods include ash, beech, birch, maple, and oak trees.

Every spring, blue and white violets blossom along the river valleys and in the lower portions of the upland regions. Marsh marigolds, skunk cabbages, and white hellebores also cover these regions in the springtime. Common shrubs and plants in the western hilly regions include azaleas, dogwoods, ferns, mountain laurels, rhododendrons, and viburnums. Mayflowers, Solomon's-seals, and trilliums are also common in the western regions. Rushes and sedges thrive along the seacoast and in the Coastal Lowlands.

Massachusetts's forests and woodlands are filled with foxes, muskrats, porcupines, rabbits, raccoons, and skunks. The tiny meadow mouse is the state's most common animal. Deer live throughout the state. Great numbers of beavers live in the streams of the Berkshire Hills. Partridge, pheasant, and other game birds are found in the fields and forests. Many kinds of water, marsh, and shore birds, especially gulls and terns, nest along the seacoast.

Bass, pickerel, sunfish, trout, and white and yellow perch swim in the state's lakes and ponds. Clams, fishes, lobsters, and oysters are found in the coastal waters. Massachusetts has many kinds of snakes. Poisonous copperheads and timber rattlesnakes live in the Berkshire and Blue hills.

Climate. Western Massachusetts is colder than the eastern part of the state. Boston, on the eastern edge of the state, has an average July temperature of 72 °F (22 °C) and an average January temperature of 29 °F (−2 °C). In the west, Pittsfield averages 68 °F (20 °C) in July and 21 °F (−6 °C) in January. Worcester, in the central portion of the state, has a July average of 70 °F (21 °C) and a January average of 24 °F (−4 °C). The highest temperature ever recorded in the state was 107 °F (42 °C) at New Bedford and Chester on Aug. 2, 1975. The lowest recorded temperature, −35 °F (−37 °C), occurred at Chester on Jan. 12 1981.

The state's *precipitation* (rain, melted snow, and other forms of moisture) ranges from about 47 inches (119 centimeters) a year in the west to about 43 inches (109 centimeters) near the coast. From 55 to 75 inches (140 to 191 centimeters) of snow falls in the western mountains of Massachusetts each year. The central part of the state averages about 49 inches (124 centimeters) a year and the coastal area about 42 inches (107 centimeters). Hurricanes occasionally lash the Massachusetts coastline. Especially destructive hurricanes hit the state in 1938, 1944, and 1985.

Economy

Service industries, taken together, account for the largest portion of Massachusetts's *gross state product*—the total value of all goods and services produced in a state in a year. Service industries include such activities as banking, health care, real estate, and trade. The manufacture of scientific instruments, electronic products, and computers is also a major part of the Massachusetts economy.

Each year, more than 25 million tourists visit Massachusetts. They contribute about $12 billion to the state's economy, primarily to the service industries. Tourism thrives around the Boston area, on Cape Cod and neighboring islands, and in the Berkshires.

Natural resources include fertile river valley soils and deposits of sand and gravel and other building materials.

Soil. Most of the river valleys have deep soils that are rich in peat. The Connecticut River Valley has the most fertile soil in the state. The marshy soils of the Coastal Lowlands, with underground peat deposits, are also quite rich. But much of the state's soil contains sand and gravel. Stones and boulders, deposited long ago by melting glaciers, are also common. These gravel and sandy acid soils are not very fertile. Farmers must treat them with large amounts of fertilizer.

Minerals. Building materials are the primary mined products of Massachusetts. Sand and gravel deposits lie mostly in east-central Massachusetts. The richest granite deposits are near West Chelmsford. Deposits of dolomitic marble are found in Ashley Falls, Lee, and West Stockbridge.

Service industries account for the largest part of the gross state product of Massachusetts. These industries operate chiefly within the state's metropolitan areas, especially the Boston area.

Community, business, and personal services form the leading service industry in Massachusetts in terms of the gross state product. This industry employs more people than any other economic activity in the state. Community, business, and personal services include private health care, private schools, law firms, computer programming and network services, and engineering companies. The Massachusetts General Hospital in Boston is one of the world's leading centers of medical research. Private universities and colleges are major employers in the state.

Finance, insurance, and real estate form the state's second-ranking service industry. Boston ranks among

the nation's major financial centers. FleetBoston, one of the nation's largest banking companies, is headquartered in the city. Fidelity, a major mutual fund firm, is also based in the city. Boston is also the home of a stock exchange and many large insurance firms and holding companies. Large financial companies are also based in Springfield and Worcester. Real estate is a major part of the economy because of the large sums of money involved in the buying and selling of property.

Wholesale and retail trade ranks next among the state's service industries. Massachusetts wholesalers purchase such goods as automobiles, groceries, and petroleum from producers and sell them to retailers. Retail establishments such as automobile dealerships, food stores, and gas stations sell goods to consumers.

Government is the fourth most important service industry in Massachusetts. Government services include the operation of public schools and hospitals, and military bases. State government activities are based in Boston. Public education is one of the state's major employers.

Transportation, communication, and utilities rank fifth among the state's service industries. Telephone companies are the major part of the transportation and communications industry. Nstar, headquartered in Boston, is the largest utility company in Massachusetts. More information about transportation and communication appears later in this section.

Production and workers by economic activities

Economic activities	Percent of GSP* produced	Employed workers: Number of people	Employed workers: Percent of total
Community, business, & personal services	27	1,504,500	38
Finance, insurance, & real estate	24	321,300	8
Wholesale & retail trade	15	811,500	21
Manufacturing	14	464,600	12
Government	9	439,400	11

Bill Gallery, Stock, Boston

High technology industries began to flourish in the Boston area during the 1970's. The worker shown here is assembling a computer board in a factory in Marlborough.

Manufacturing. The state's manufactured goods have a *value added by manufacture* of about $46 billion a year. Value added by manufacture represents the increase in value of raw materials after they become finished products.

Computer and electronic products are by far the state's leading manufactured product in terms of value added by manufacture. Computer equipment, including microchips, are a major part of this industry. Digital Equipment, one of the nation's largest computer companies, is headquartered in Massachusetts. The Greater Boston area has many factories that make computers. Also important is communications equipment, which includes broadcasting devices, military communications systems, and telephone equipment. Factories in the Boston area also produce automation control devices, oscilloscopes, and other instruments.

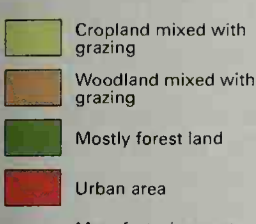
Fabricated metal products rank second in terms of value added by manufacture. Such fabricated metal products as ammunition, guns, hand tools, knives, stampings, and valves are made in Massachusetts.

Chemicals rank third. Pharmaceuticals, cleaning products, and photographic materials are the state's leading types of chemical products.

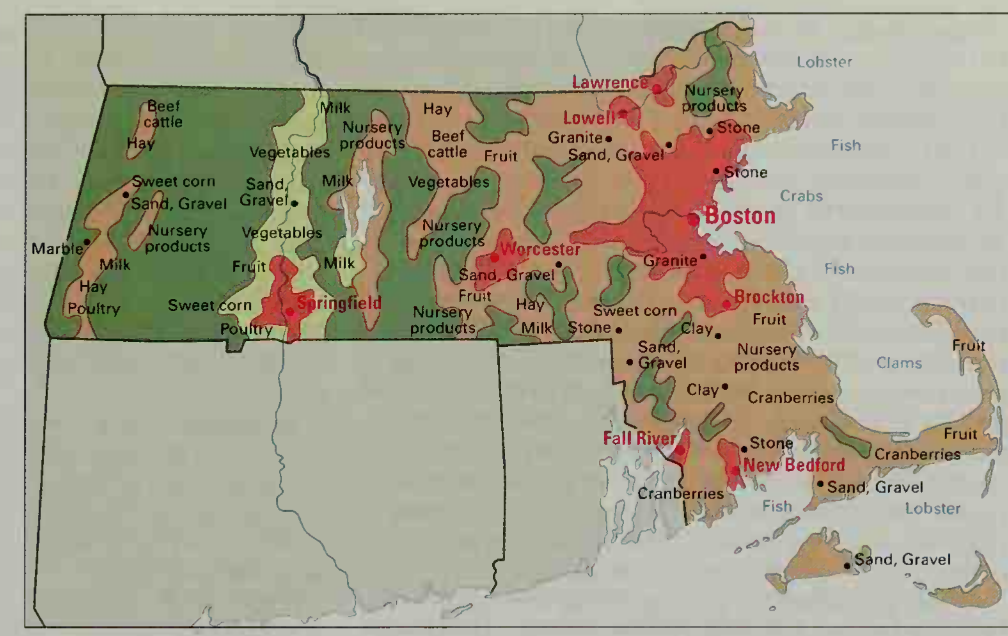
Machinery ranks fourth among the manufactured products. Types of machinery manufactured in Massachusetts include metalworking machinery, printing equipment, and machines for the computer industry.

Other types of products manufactured in Massachusetts include food products, paper products, plastics products, printed materials, and transportation equipment. Bread, candy, dairy products, fish products, and soft drinks are the main food products of Massachusetts. Stationery, coated papers, and packaging materials are important paper products made in the state. A variety of plastics products are manufactured throughout the state. Most printed materials are manufactured in Boston. Books and newspapers are the state's major kinds of printed materials. Leading transportation products include motor vehicle parts and aircraft engines.

Agriculture. Farmland covers about 11 percent of the land area of Massachusetts. The state has approximately 6,100 farms.



Greenhouse and nursery products are the leading source of farm income in Massachusetts. They include such plants as flowers and ornamental shrubs.



Cranberries rank second in value among farm products in Massachusetts. The state produces about a third of the cranberries grown in the United States. Most of the cranberries are grown in bogs in marshy areas of the coastal lowlands.

Milk is the leading source of income from livestock

Economy of Massachusetts

This map shows the economic uses of land in Massachusetts and where the state's leading farm and mineral products are produced. Major manufacturing centers are shown in red.

WORLD BOOK map

farming in Massachusetts. The state's main dairy-farming region lies just east of the Connecticut River. Eggs are another major source of livestock income. Hay, the state's major field crop, is used as feed for dairy cattle. Massachusetts farmers also produce apples, beef cattle, and sweet corn.

Mining. The production of sand and gravel and crushed stone provides most of the state's mining income. Central Massachusetts leads in sand and gravel production. Sand and gravel are used to make concrete and roadbeds. Traprock quarries in eastern Massachusetts are the main source of crushed stone. Crushed traprock is used to make asphalt pavement and other road surfaces. Clays, granite, and peat are also mined in Massachusetts.

Fishing industry. Massachusetts ranks among the leading commercial fishing states. The state's annual fish catch is valued at more than $250 million. Several Massachusetts ports rank among the leading United States ports in annual fish catch. New Bedford accounts for about half the scallops produced in the United States. Gloucester's chief products include cod, flounder, haddock, ocean perch, and whiting. The fishing industry in Boston specializes in cod and haddock. Other valuable products of the Massachusetts fishing industry include clams, crabs, hake, herring, lobster, pollock, squid, swordfish, and tuna.

Electric power. Petroleum-burning plants provide nearly 40 percent of the state's electric power. Plants that burn coal produce about 30 percent, and nuclear power plants produce another 20 percent. Plants that burn natural gas provide about 7 percent of the state's electric power. Hydroelectric power also produces a small amount. Massachusetts contributes to the New England power pool and shares electric power with the other New England states.

Transportation. Logan International Airport in Boston is the busiest airport in the state and one of the busiest airports in the world. Eleven railroads provide freight service in the state, and passenger trains serve several cities. Boston has a large mass transit system.

Massachusetts has about 31,000 miles (50,000 kilometers) of roads and highways. The Massachusetts Turnpike, a toll road, stretches westward from Boston to the New York state line. Two major highways swing in an arc around Boston—Route 128 and, farther west, Route 495.

Boston is the main seaport for Massachusetts and for much of New England. Boston's port handles mainly containerized goods and petroleum products. Fall River, the second largest port in Massachusetts, handles petroleum products, motor vehicles, and other large cargoes.

Communication. In 1639, Stephen Daye established the first printing press in the English colonies in Cambridge. This was only 19 years after the Pilgrims landed in Massachusetts. In 1640, Daye printed the *Bay Psalm Book,* the first English-language book published in America.

The first two newspapers in the colonies were published in Boston. *Publick Occurrences Both Forreign and Domestick* was established in 1690. *The Boston News-Letter* was established in 1704. *The Boston Newsletter* was the first successful newspaper published in America.

Today, Massachusetts publishers issue about 300 newspapers. About 40 of the newspapers are dailies. The chief newspapers include *The Boston Globe,* the *Boston Herald, The Christian Science Monitor* in Boston, *The Eagle-Tribune* in Lawrence, *The Enterprise* in Brockton, *The Middlesex News* in Framingham, *The Patriot Ledger* in Quincy, the *Springfield Union-News,* the *Sun* in Lowell, and the *Telegram & Gazette* in Worcester. Massachusetts publishers produce approximately 400 periodicals.

The state's first radio station, WGI, began broadcasting in Medford in 1920. The first television stations in Massachusetts, WBZ-TV and WNAC-TV, started in Boston in 1948. Today, Massachusetts has about 150 radio stations and 20 television stations. Cable television systems and Internet providers serve communities statewide.

Government

Constitution. Massachusetts adopted its Constitution in 1780, during the Revolutionary War. Its Constitution is the oldest state constitution still in use, though it has been *amended* (changed) more than 100 times.

The Constitution provides for two kinds of amendments. *Legislative amendments,* the more common type, are introduced by members of the legislature. *Initiative amendments* are introduced to the legislature on petitions signed by a specified number of voters. Both types of amendments must be approved during joint sessions of the legislature. Legislative amendments require approval by a majority of the legislature. Initiative amendments must be approved by one-fourth of the legislators. All amendments must then be approved in a similar manner by the next legislative body. Finally, an amendment must be approved by a majority of the people voting on it in a general election. An initiative amendment must also receive approving votes equal to 30 percent of the number of ballots cast in the election.

A third procedure for a constitutional amendment, set by precedent in 1779, allows for the calling and holding of a constitutional convention. Before a constitutional convention can meet, it must be approved by a majority of the legislators and two-thirds of Massachusetts's voters.

Executive. The governor and lieutenant governor of Massachusetts are elected to four-year terms. The voters also elect the secretary of the commonwealth, the treasurer and receiver general, the attorney general, and the state auditor to four-year terms.

The governor is assisted by a six-member cabinet, made up of the appointed heads of the state's six executive departments. The governor appoints the heads of state departments and the members of state agencies and nominates judges. The governor's judicial nominations are subject to approval by the Executive Council. The Executive Council consists of the lieutenant governor and one member elected from each of eight state districts.

Legislature, called the *General Court,* consists of a 40-member Senate and a 160-member House of Representatives. Each of the state's 40 senatorial districts elects one senator, and each of the representative districts elects one representative. All members of the legislature serve two-year terms.

Both houses meet every year beginning on the first Wednesday in January. The session is scheduled to end on the Tuesday that precedes the first Wednesday in January of the second year of session. But it may end earlier if the legislature and the governor agree that all business is completed.

Courts. All judges in Massachusetts are appointed by

The state governors of Massachusetts

*Democratic-Republican. †Know-Nothing.

the governor and may serve until the age of 70. The Supreme Judicial Court is the state's highest court. It has a chief justice and six associate justices. The Appeals Court handles appeals of civil and criminal cases. It consists of a chief justice and 13 associate justices. The Superior Court is the main trial court in the state. This court has a chief justice and 76 associate justices. Other state courts include district, housing, juvenile, land, Boston Municipal, and probate and family courts.

Local government in Massachusetts is centered in 47 chartered cities and in 304 incorporated towns. Most of the cities have a mayor-council government. Some use a council-manager system. A *town* in Massachusetts is similar to a *township* in other states. Like a township, a town may consist of several villages and rural areas. The entire town is governed as a single unit.

Towns in Massachusetts are governed by annual town meetings. Many small towns hold open meetings at which any voter in the town can participate. Most large towns hold representative meetings at which only elected members may vote. Voters express their opinions about town issues and make plans for the coming year. They also choose officials called *selectmen* to carry out the town's business until the next meeting. Massachusetts cities and towns have *home rule* (self-government). They may pass some laws dealing with local matters without interference from the state government.

Counties serve mainly as judicial boundaries. The state's 14 counties are divided into districts. Each county has one or more district courts. Each county elects a register of deeds, a register of probate and insolvency, a district attorney, a sheriff, and clerks of court. Since 1997, the governments of six Massachusetts counties have been abolished, and many of their functions have been absorbed by the state government. Voters in these counties do not elect a register of deeds. All the eight remaining counties except for Nantucket and Suffolk elect commissioners and treasurers.

Revenue. Taxes provide more than half of Massachusetts's *general revenue* (income). Most of the rest comes from federal grants and programs, and from state government services. Important sources of tax revenue include a personal income tax, a general sales tax, and taxes on corporate income and motor fuels.

Politics. Massachusetts has elected about an equal number of Democrats and Republicans to the U.S. Senate. More Republicans have served as governor. In presidential elections since 1900, more Democrats have won the state's electoral votes. For the state's voting record in presidential elections, see **Electoral College** (table).

History

Indian days. Indians probably lived in the Massachusetts region more than 3,000 years ago. Early European explorers saw Algonquian Indians in the region about 1500. The Algonquian tribes included the Massachusett, Nauset, Nipmuc, Pennacook, Pocomtuc, and Wampanoag. Disease killed many of these Indians in 1616 and 1617. By the time colonists arrived in 1620, the Indian population had fallen from about 30,000 to about 7,000.

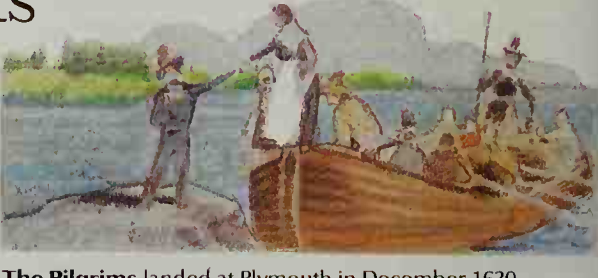
Early exploration. The first Europeans to reach Massachusetts were probably Vikings led by Leif Ericson in about the year 1000. Some French and Spanish fishermen may have visited the region during the 1400's. Historians believe John Cabot may have sighted the Massachusetts coast in 1498.

In 1602, Bartholomew Gosnold of England landed on Cuttyhunk Island in the Elizabeth Islands. He gave Cape Cod its name. In 1605 and 1606, Samuel de Champlain of France drew maps of the New England shoreline. John Smith, an English sea captain, sailed along the coast of Massachusetts in 1614. Smith's book, *A Description of New England,* guided settlers to the coast.

The Pilgrims. In the 1500's, some members of the Church of England, known as *Puritans,* favored reforms to "purify" the church. By the late 1500's, some Puritan congregations had broken away from the church entirely and had become known as *Separatists.* Some Separatists sought religious freedom in Holland, then decided to begin a new life in America.

The early English settlers of New England became known as the *Pilgrims.* On Sept. 16, 1620, 41 Separatists and 61 other people from England became the first group of Pilgrims to journey to America. These Pilgrims sailed from Plymouth, England, in the *Mayflower.* That November, the *Mayflower* anchored in what is now Provincetown harbor. Before leaving the ship, the Pilgrims drew up a plan of self-government, which they called the Mayflower Compact. In December, they sailed across Cape Cod Bay and settled in Plymouth.

The Pilgrims suffered great hardships during their first winter in America. They had little food other than the game they could hunt. Their houses were crude bark shelters. About half the settlers died during the winter of 1620-1621. Early in 1621, the Pilgrims became friendly with some Indians. The Indians taught them how to plant corn and beans. By the time cold weather came again, the settlers were living more comfortably. They had enough food to last the winter. The Pilgrims celebrated the first New England Thanksgiving in 1621.

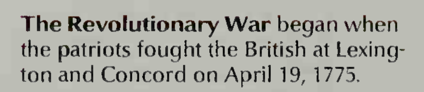


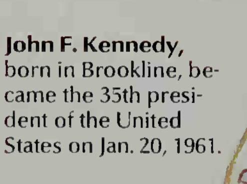
More settlers came to the Plymouth Colony during the years that followed. Within 20 years after the Pilgrims landed, Plymouth Colony had eight towns and about 2,500 people.

Massachusetts Bay Colony. In 1628, a joint-stock company of English Puritans sent a group of settlers to the Massachusetts Bay area. They joined a small settlement already there, later named Salem. In 1629, King Charles I of England granted the company a charter. The charter gave the company a stronger right to settle and govern the area. In 1630, the English lawyer John Winthrop led about 1,000 Puritans to Salem. Later that year, they left Salem and founded a settlement in the area of present-day Boston. The colony prospered. By 1640, the Massachusetts Bay Colony had about 10,000 settlers.

Colonial days. The Massachusetts Bay Colony established political freedom and a representative form of government. In 1641, the first code of laws of the colony was set down in a document known as the Body of Liberties. But the Puritans permitted no religion except their own in the colony. Some religious groups were put out of the colony, and others left on their own.

Historic Massachusetts





The Pilgrims landed at Plymouth in December 1620, after a voyage of more than three months from England.

The Boston Tea Party of Dec. 16, 1773, was a protest by colonists. Dressed as Indians, they threw cargoes of tea from British ships into Boston Harbor.

The Revolutionary War began when the patriots fought the British at Lexington and Concord on April 19, 1775.

The telephone was invented by Alexander Graham Bell in Boston. It was patented on March 7, 1876.

John F. Kennedy, born in Brookline, became the 35th president of the United States on Jan. 20, 1961.

WORLD BOOK illustrations by Kevin Chadwick

Important dates in Massachusetts

1602 Bartholomew Gosnold, an English explorer, visited the Massachusetts region.

1620 The Pilgrims landed at Plymouth.

1630 The Puritans founded Boston.

1636 Harvard became the first college in the colonies.

1641 Massachusetts adopted its first code of law, the Body of Liberties.

1675-1676 Massachusetts colonists won King Philip's War against the Indians.

1689-1763 Massachusetts colonists helped the British win the French and Indian Wars.

1691 Plymouth and the Massachusetts Bay colonies were combined into one colony.

1764 The colonists began to resist enforcement of British tax laws.

1770 British soldiers killed several colonists in the Boston Massacre.

1773 Patriots dumped British tea into Boston Harbor during the Boston Tea Party.

1775 The Revolutionary War in America began at Lexington and Concord.

1780 Massachusetts adopted its Constitution.

1788 Massachusetts became the sixth state in the Union on February 6.

1797 John Adams of Massachusetts became president of the United States.

1807 The Embargo Act ruined Massachusetts shipping and led to the rise of manufacturing.

1825 John Quincy Adams of Massachusetts became president of the United States.

1912 A strike of textile workers at Lawrence led to improved conditions in the textile industry.

1919 Settlement of the Boston police strike brought national prominence to Governor Calvin Coolidge.

1959 The U.S. Navy launched its first nuclear-powered surface ship, the cruiser *Long Beach,* at Quincy.

1961 John F. Kennedy of Massachusetts became president of the United States.

1971 Massachusetts began a reorganization of its state government, including the consolidation of more than 150 smaller agencies into about 10 new departments.

1988 Massachusetts celebrated its statehood bicentennial.

Illustration (1907) by Howard Pyle (Granger Collection)

The Salem Witchcraft Trials, held in 1692, resulted in the execution of 19 people, both men and women, who were convicted as witches. These were the last witchcraft executions in America.

These Massachusetts settlers helped colonize other parts of New England in their search for religious freedom. They established settlements in Connecticut in 1635, Rhode Island in 1636, New Hampshire in 1638, and Maine in 1652. Connecticut and Rhode Island soon became independent colonies. New Hampshire did not separate from Massachusetts until 1680. Maine remained a part of Massachusetts until 1820.

King Philip's War. Massasoit, chief of the Wampanoag tribe, had been a close friend of the Plymouth colonists. But his son, King Philip, who became chief in 1662, feared the white settlers. He believed that they would wipe out the Indians and seize their lands.

In 1675, King Philip rose up against the colonists in an attempt to protect his people and their homelands. He planned to massacre all white settlers in New England. The struggle became known as King Philip's War. White and Indian settlements were burned and hundreds of men, women, and children died on both sides. An Indian serving with colonial troops killed King Philip in 1676, ending the war in southern New England. Fighting continued in northern New England until 1678. The Indian danger in eastern, central, and southern Massachusetts ended. But a tenth of Massachusetts' white male population had been wiped out.

Troubles with England. Although Massachusetts belonged to England, the colonists often resisted controls from across the sea. England believed that its colonists should trade only with the mother country. But many Massachusetts colonists disagreed, and traded with other countries. Attempts at stricter control had little effect on some of the colonists. In 1684, King Charles II canceled the Massachusetts charter. James II became king of England in 1685.

In 1686, King James established a government in Massachusetts and other northern colonies called the Dominion of New England. The king made Sir Edmund Andros governor of the dominion. King James was overthrown in 1688. His daughter, Mary, and her husband, Prince William of Orange, became joint rulers of England. When the Massachusetts colonists received the news, they put Andros out of office and set up a temporary government of their own. William and Mary granted a new charter to Massachusetts in 1691. This charter combined the Plymouth Colony with the Massachusetts Bay Colony and added the island of Martha's Vineyard.

In 1692, Sir William Phips became Massachusetts' first royal governor. One of his most important acts was to end the persecution of persons believed to be witches (see **Witchcraft**).

The French and Indian wars. In 1689, the first of the four French and Indian wars broke out. The English colonists fought the French colonists and France's Indian allies. Between 1689 and 1713, settlers along Massachusetts' northern and western borders fought off continuous French and Indian attacks. In 1713, Great Britain, France, and other European nations signed a peace treaty at Utrecht, the Netherlands. An era of prosperity began in Massachusetts. Dozens of towns sprang up in the central and western areas of the colony. But the wars broke out again in the 1740's. They finally ended in 1763 with victory for the British.

Pre-Revolutionary days. The colonial wars left Britain in debt. To help pay for defense of the colonies, the British placed severe taxes on the American colonies. The Massachusetts colonists ignored most of these taxes. But the Stamp Act of 1765 led to bitter protests (see **Stamp Act**). The cry of "no taxation without representation" spread through the colony. An angry mob destroyed the lieutenant governor's home. The presence of British soldiers in Boston added to the bitterness between the colonists and the Crown. In 1770, British soldiers killed several colonists while fighting a Boston mob. This incident became known as the Boston Massacre. In 1773, angry colonists staged the Boston Tea Party to protest a British tea tax. The colonists dumped 342 chests of British tea into Boston Harbor.

The British passed a series of measures to punish the colonists. But these measures merely angered the colonists more and helped bring all the American colonies together. On April 18, 1775, British troops marched from Boston to seize or destroy supplies of gunpowder hidden by the colonists at Concord. Paul Revere and others rode across the Massachusetts countryside to warn their fellow patriots that the British were coming. The next morning, American minutemen at Lexington fought the opening battle of the Revolutionary War (see **Minutemen**).

The Revolutionary War began in Massachusetts. Much of the early fighting took place on Massachusetts soil. Massachusetts soldiers fought bravely at Lexington,

Boston Harbor in 1768 is shown in an engraving by Paul Revere. British warships are anchored in the harbor.

Massachusetts Historical Society

Concord, and at Bunker Hill. On July 3, 1775, General George Washington took command of the Continental Army in Cambridge. In the spring of 1776, Washington drove the British out of Boston in the first major American victory of the war. Much of the fighting moved out of Massachusetts and into New York, New Jersey, and Pennsylvania in 1776. But Massachusetts continued to send soldiers and supplies to the American forces. At sea, Massachusetts ships inflicted heavy damage on British merchant ships.

The effects of the Revolutionary War in Massachusetts were felt most by the farmers. Prices of farm products dropped after the war ended in 1783. Money became so scarce that many farmers could not pay their taxes or debts. The farmers, facing the danger of losing their farms and going to prison, grew restless. In September 1786, Daniel Shays led a group of angry farmers to protest in front of the courthouse in Springfield. Fighting broke out between the farmers and government troops. The fighting, which became known as Shays's Rebellion, ended when the farmers surrendered in February 1787.

Massachusetts farmers also opposed *ratification* (approval) of the United States Constitution. They felt that the Constitution was more favorable to trade and finance than to agriculture. On Feb. 6, 1788, Massachusetts ratified the Constitution and became the sixth state in the Union. Massachusetts ratified the Constitution only on the condition that certain amendments concerning individual rights be added. The Bill of Rights to the U.S. Constitution went into effect on Dec. 15, 1791.

Progress as a state. Massachusetts prospered during its early years as a state. In the early 1800's, France and Britain were at war. American shipowners who were willing to send their vessels into European waters could make huge profits. But both the British and the French tried to attack ships bound for their enemy's ports. President Thomas Jefferson feared that such an attack on an American ship might force the United States into the war. In 1807, he persuaded Congress to pass the Embargo Act, which stopped American exports to other countries and prohibited U.S. ships from sailing into foreign ports.

Hardships resulting from the embargo and the War of 1812 forced a new way of life upon the people of Massachusetts. Goods had to be manufactured at home rather than imported. In 1814, Francis Cabot Lowell built a textile factory in Waltham. It was one of the first factories in the United States. A number of other textile mills were soon operating in eastern Massachusetts. With the opening of New York's Erie Canal in 1825, crops could be brought to New England from the west. Farming in Massachusetts suffered. Many farmers left the state or went to work in factories.

The whaling industry flourished in New Bedford, Nantucket, and Boston until the early 1860's. It declined after kerosene replaced whale oil.

The *abolitionist* (antislavery) movement received wide support in Massachusetts. In 1831, William Lloyd Garrison of Boston began publishing his antislavery newspaper *The Liberator*. In 1832, abolitionists formed the New England Anti-Slavery Society in Boston. The society helped slaves escape to Canada. Some people in Massachusetts opposed the abolitionists. They objected to what they considered extremist tactics. They also feared that the Southern planters might cut off the cotton supply for the Massachusetts textile industry.

In 1850, Congress passed a series of acts which it hoped would settle the conflict between slave-owners and those who opposed slavery. These acts were called the Compromise of 1850 (see **Compromise of 1850**). Senator Daniel Webster of Massachusetts defended the compromise as necessary to preserve the Union. But many people in Massachusetts disagreed. Abraham Lincoln and the Republican Party carried the state in the 1860 presidential election.

Massachusetts gave strong support to the Union during the Civil War (1861-1865). The state furnished more than 125,000 men to the Union Army and about 20,000 men to the Navy. Massachusetts shipbuilders built and equipped many Union ships.

Industry in the state expanded after the war. The textile industry prospered, and the leather and metal products industries also grew rapidly. Thousands of immigrants poured into the state to meet the great demand for industrial labor.

During the mid-1870's, inventor Alexander Graham Bell developed the telephone in Boston. A telephone

line between Boston and Providence, Rhode Island, was installed in 1881.

The early 1900's. Massachusetts's population swelled to about 2 $\frac{1}{2}$ million by 1900. Approximately 30 percent of these people came to the United States from other countries. This huge number of people, with their variety of backgrounds, brought new problems to the state. Communities had to provide such services as water supply, sewerage, housing, and police protection. Industrial workers became unhappy with wages and working conditions. A textile strike in Lawrence in 1912 brought nationwide attention to poor working conditions in the textile industry. Improvements followed the strike.

The United States entered World War I in 1917. The Yankee (26th) Division of Massachusetts was the first National Guard division to reach the battlefields of France. Prices climbed in Massachusetts during the war, and workers demanded higher wages to meet the increased cost of living. But often such demands were not met. In 1919, the mayor of Boston refused to let the city's police form a union. About three-fourths of the Boston police force went on strike. Governor Calvin Coolidge helped end the strike by sending the National Guard into Boston. Coolidge gained nationwide fame because of his action and was elected vice president of the United States in 1920. Three years later, Coolidge became president following the death of President Warren G. Harding.

Massachusetts's economy suffered during the 1920's because of competition from the textile and shoe industries in Southern and Western states. But other industries continued to prosper. In 1929, the Great Depression hit the United States. Massachusetts carried on its own unemployment-relief program until the federal government organized nationwide programs. In 1938, a hurricane killed hundreds of persons in Massachusetts and caused great property damage.

The mid-1900's. The state's economy soared during World War II (1939-1945). Massachusetts factories and shipyards produced huge quantities of war materials and supplies.

Many traditional Massachusetts industries, including the manufacture of shoes and textiles, declined greatly during the 1950's and 1960's. Many industries in the state began to switch to space and rocket research or the production of electronics equipment. Hundreds of research laboratories developed in and around Boston, using the facilities and personnel of the many colleges and universities in the area. The United States Navy launched its first nuclear surface ship, the cruiser *Long Beach,* at Quincy in 1959.

Like many other states, Massachusetts faced serious racial problems during the mid-1900's. In 1957, the state legislature prohibited segregation in public housing. New legislation in 1963 made segregation illegal in most private dwellings as well. During the mid-1970's, Boston's public schools were desegregated by order of a federal court.

During the 1950's and 1960's, the Kennedy family of Brookline became powerful in state and national politics. John F. Kennedy served as president of the United States from 1961 until his assassination in 1963. When elected president, he was representing Massachusetts in the U.S. Senate. His brother, Robert F. Kennedy, served as U.S. attorney general from 1961 to 1964. Robert Kennedy was elected to the U.S. Senate from New York in 1964. He was assassinated in 1968 while campaigning for the Democratic presidential nomination. The youngest Kennedy brother, Edward M. Kennedy, has served as a U.S. senator from Massachusetts since 1962.

Recent developments. In Massachusetts, as in other states, large numbers of people and industries have moved from the cities to suburbs since the mid-1900's. Massachusetts has remained a center for military research and development, and it is a leader in banking, education, insurance, and medical care. But Massachusetts has faced economic hardships. A nationwide recession in the early 1990's hit Massachusetts and other northeastern states especially hard.

Today, Massachusetts officials are working to ease several problems common to many states. These problems include air and water pollution, a housing shortage in cities, and racial tension.

Massachusetts, University of, is a state-supported coeducational university. It has campuses in Amherst, Boston, Lowell, North Dartmouth, and Worcester.

The Amherst campus has colleges of arts and sciences and of food and natural resources, and schools of education, engineering, health science, management, and physical education. It grants associate, bachelor's, master's, and doctor's degrees. The Boston campus has colleges of arts and sciences, management, and public and community service; a school of nursing; and a college of education. It offers bachelor's, master's, and doctor's degrees. The Lowell campus has colleges of arts and sciences, education, engineering, fine arts, health professions, and management. It awards associate, bachelor's, master's, and doctor's degrees. The North Dartmouth campus has colleges of arts and sciences, business and industry, nursing, and visual and performing arts. It grants bachelor's and master's degrees. The university's medical school and graduate schools of nursing and biomedical science are part of the medical center located in Worcester.

The University of Massachusetts and Amherst, Hampshire, Mount Holyoke, and Smith colleges have set up cooperative programs. One program allows a student to take courses at any of the other schools if they are not

offered at his or her own school. The schools also offer doctor's degrees jointly in several fields.

The university was chartered in 1863 as Massachusetts Agricultural College. It took the name University of Massachusetts in 1947.

Massachusetts Bay Colony was the largest and most successful early New England settlement. It was established in 1628 by the New England Company, a joint-stock company composed of English Puritans. That year, John Endecott led the first group of colonists to Naumkeag, an English settlement that he renamed Salem. In 1629, King Charles I granted a new charter that changed the name of the company to the Massachusetts Bay Company. In 1630, the company's new governor, John Winthrop, brought the charter and about 1,000 more people to settle the Massachusetts Bay region, including the area that is now Boston.

The Puritans observed a simple form of worship that did not include the ceremonies of the Church of England. Each Puritan community established self-governing congregations. The Puritans wanted to make their church and society an example for people in other parts of the world to follow. Newcomers to the colony were expected to follow the Puritans' religious beliefs and practices. People who refused were sent back to England or expelled to such other settlements as Rhode Island and New Hampshire.

England rarely interfered with the colony's government and trade. Beginning in 1660, Puritans refused to obey new English trade laws. In 1684, the colony lost its charter. In 1691, King William III granted a new charter that included Plymouth Colony as part of the Massachusetts Bay Colony. This charter lasted until the Revolutionary War in America began in 1775.

The colonists of the Massachusetts Bay Colony made many contributions to American life. Among the most important of these were a practical, local self-government and a love of learning. T. H. Breen

Massachusetts Institute of Technology (MIT) is a private coeducational university in Cambridge, Massachusetts. It is famous for its scientific research activities and for combining education and research in all programs. The institute includes schools of architecture and planning, engineering, humanities and social science, management, and science. All these schools offer graduate programs. MIT grants bachelor's, master's, and doctor's degrees.

MIT has research centers in several broad fields, including cancer, communications sciences, earth and life sciences, energy, international and urban studies, and nuclear and space science. More than 70 laboratories at the institute conduct research in all fields represented at MIT. The institution has a wide sports program and sponsors activities in drama, music, publications, and other cultural areas.

MIT was founded in Boston in 1861 and moved to Cambridge in 1916. The campus extends for more than a mile (1.6 kilometers) along the Charles River.

Massage, *muh SAHZH,* is a method of manipulating the skin to produce healthful effects on the skin and underlying tissues. "Western massage" consists of stroking, rubbing, kneading, and striking the skin, usually with the hands or fingers. "Eastern massage" includes these same methods, but it also focuses on applying pressure at specific points of the body according to acupuncture techniques (see **Acupuncture**).

Massage can improve blood circulation, relax muscles, stimulate nerve endings in the skin, and promote a feeling of general well-being. Depending on how the massage is given, its effects can be either relaxing or invigorating. Massage is often used to promote healing of an injury or muscle soreness, or to relieve tension. People who give massages should be well trained, and they should be knowledgeable about physiology.

Mary T. Moffroid

Massasoit, *MAS uh SOYT* (1580?-1661), was a chief of the Wampanoag tribe of Indians who lived in what is now southern Massachusetts and Rhode Island. He made a treaty with Governor John Carver of Plymouth Colony in the spring of 1621, shortly after the Pilgrims landed in America.

Massasoit agreed that his people would not harm the Pilgrims as long as he lived. In turn, the Pilgrims guaranteed to protect the Indians and their rights. Massasoit kept the peace all his life.

In the autumn of 1621, the Pilgrims harvested their

Bronze statue (1921); Artstreet

first crop of Indian corn and invited Massasoit and about 90 of his people to share the first Thanksgiving feast. The Indians brought five deer to add to the feast, which lasted three days.

When Massasoit died, he was succeeded by his elder son, Wamsutta, whom the colonists called Alexander. Massasoit's younger son, Metacomet, called King Philip by the colonists, succeeded Alexander. James Axtell

See also **Philip, King; Plymouth Colony** (The first year).

Massenet, *MAS uh NAY,* **Jules,** *zhool* (1842-1912), was a French composer best known for his operas. Massenet's operas are noted for their dramatic sense and graceful melodies. Perhaps the best known of his 25 operas is *Manon* (1884). The leading roles of Manon and her lover, Des Grieux, are still popular with singers. Massenet's other operas include *Werther* (1892), *Thaïs* (1894), and *Don Quichotte* (1910). Massenet also composed orchestral works, works for orchestra and voice, and more than 200 songs that rank among his best compositions.

Jules Émile Frédéric Massenet was born in Montaud, near St.-Étienne. His early piano lessons with his mother helped him gain admission to the Paris Conservatory at the age of 11. From 1878 to 1896, he was a professor of composition at the conservatory. Stewart L. Ross

Massey, Vincent (1887-1967), was the first Canadian-born governor general of Canada. He served in this position from 1952 to 1959. All previous governors general had come from Britain. Massey traveled extensively in Canada, promoting a feeling of national identity among Canada's French- and English-speaking citizens.

Charles Vincent Massey was born in Toronto. He received a bachelor's degree from the University of Toronto and a master's degree from Balliol College of Oxford University. Massey was a history lecturer at the university from 1913 to 1915. From 1921 to 1925, he was president of the family's Massey-Harris Company, which manufactured farm machinery.

In 1926, Massey joined the Canadian delegation at the Imperial Conference in London. Canada's independent status in the British Commonwealth of Nations, as the British Empire then became known, was recognized at this conference. Massey served as Canada's first minister to the United States from 1926 to 1930. From 1935 to 1946, he was High Commissioner for Canada in Britain.

In 1949, the Canadian government made Massey chairman of the Royal Commission on National Development in the Arts, Letters and Sciences. The commission's work led to increased government financial aid to help promote the arts and sciences. Massey served as chancellor of the University of Toronto from 1947 to 1953. In 1961, he founded Massey College, a graduate college of the university. Massey published several volumes of his speeches. He also wrote an autobiography, *What's Past Is Prologue* (1963). Jacques Monet

Massine, *mah SEEN,* **Léonide,** *lay aw NEED* (1896-1979), was a great Russian dancer and *choreographer* (dance creator). Massine invented a dance form called *symphonic ballet,* in which *abstract* (storyless) ballets were choreographed to well-known symphonies. His *Les Présages* (1933) to Tchaikovsky's Symphony No. 5 was the first of these ballets. He also choreographed and danced in many other kinds of ballets, such as *The Three-Cornered Hat* (1919), *Le Beau Danube* (1933), and *Gaîté Parisienne* (1938). As a dancer, he had a strong personality, especially in comic or character roles.

Massine was born in Moscow. He joined Sergei Diaghilev's Ballets Russes as a dancer in 1913. By 1917 he had created several ballets, including the first cubist ballet, *Parade.* Massine was director, dancer, and choreographer of the Ballets Russes from 1932 to 1938 and of the Ballet Russe de Monte Carlo from 1938 to 1941. He also appeared in films, including *The Red Shoes* (1948) and *Tales of Hoffmann* (1951). Dorothy Lourdou

Massinger, *MAS uhn juhr,* **Philip** (1583-1640), an English playwright, is best known for his comedy *A New Way to Pay Old Debts* (1621 or 1622). The play's chief character, the monstrous villain Sir Giles Overreach, so appealed to actors and audiences that the play was performed longer than any other non-Shakespearean play of the 1600's. The character of Sir Giles Overreach is based on the scandalous activities of a real nobleman, and the action is taken from Thomas Middleton's play *A Trick to Catch the Old One* (1608).

Massinger was born in Salisbury of a prominent family. He wrote nearly 40 plays, some of them in collaboration with other playwrights. About 20 of his plays survive. From 1625 to his death, Massinger wrote one or two plays a year for The King's Men, the leading acting company of the day. Albert Wertheim

Masson, *mah SAWN,* **André,** *ahn DRAY* (1896-1987), a French painter, was an important member of the surrealism art movement during the 1920's. Masson attempted to find the sources of his art in the subconscious, to develop his work independently of rules, and to create works that are spontaneous and unpremeditated. He believed that there are unexplored levels of reality which surpass conventional reality. Masson abandoned conscious artistic intentions in favor of painting by impulse or even by accident. He turned to a technique called *automatism.* In *automatic painting,* artists try to let their brushes move freely on the canvas to allow their subconscious mind create the images.

Masson was born in Balagny-sur-Thérain, France, near Paris. Early in his career he was influenced by the cubist style. By 1924, Masson had become involved with French author André Breton, surrealism's leader and chief theorist. Masson's most important surrealist painting was achieved between 1924 and 1929. After that, he worked in a variety of styles. He lived in Spain from 1934 to the outbreak of the Spanish Civil War in 1936. He moved to the United States after World War II began in 1939. In the United States, Masson exerted a major influence on American abstract expressionists, including Jackson Pollock, Willem de Kooning, and William Baziotes. Masson returned to France after the end of the war in 1945. Stephen C. Foster

Mastectomy, *mas TEHK tuh mee,* is the surgical removal of a breast. Surgeons generally perform a mastectomy to treat women for breast cancer. The operation removes cancer cells in the breast and prevents them from spreading to other body organs.

There are four main types of mastectomies. The type of mastectomy performed depends on the size and location of the tumor, the extent of the cancer, and the age and health of the patient. The *conventional radical mas-*

tectomy removes the breast, the lymph nodes in the underarm, and the chest wall muscles. The *modified radical mastectomy* removes the breast and the underarm lymph nodes. A *simple mastectomy,* also called *total mastectomy,* removes only the breast. A *subcutaneous mastectomy* removes breast tissue but spares the overlying skin and nipple.

William S. Halsted, an American surgeon, developed the conventional radical mastectomy in 1894. It remained the most common surgery for breast cancer until the 1970's. This operation leaves a long scar and hollow areas where chest muscle is removed. It often limits use of the arm. By the late 1970's, studies showed that modified radical mastectomy, which causes less deformity than the conventional surgery, treated cancer just as effectively. Today, the modified radical is the most common surgery used to treat breast cancer. It leaves enough tissue for reconstruction and preserves use of the arm.

Most mastectomy patients wear an artificial breast called a *prosthesis.* Some women have the breast reconstructed surgically. Surgeons may replace the breast using tissue from other parts of the body. In other cases, surgeons insert an implant filled with salt water or a material called *silicone gel* under the chest muscle. In 1992, the United States Food and Drug Administration limited use of silicone gel implants to women enrolled in studies to determine if these implants caused health problems. Results of studies in the mid-1990's convinced most doctors that silicone implants rarely cause harm.

When a breast cancer is small, a *lumpectomy* may preserve the breast. This operation removes the cancerous tumor, a margin of normal tissue, and the underarm lymph nodes. The breast is then treated with radiation to kill any remaining cancer cells. Major studies in the 1980's and 1990's showed that lumpectomy with radiation is as effective as mastectomy in treating small cancers. Melvin J. Silverstein

Masters, Edgar Lee (1868-1950), was an American author. He wrote novels, poetry, plays, biography, and history, but he became famous chiefly for one volume of poems, *Spoon River Anthology* (1915).

Masters modeled the *Anthology* on a collection of ancient Greek short poems and sayings called *The Greek Anthology.* Spoon River is an imaginary Midwestern village. Masters's work consists of more than 200 short poems in free verse. Each poem is spoken by a former resident of the village, now dead and buried in the Spoon River cemetery. Each of the dead persons seeks to interpret, from the grave, the meaning of life on earth.

Through the poems, Spoon River comes to life again. Sometimes the histories of whole families are told. Spoon River is seen as a place where life was hard but could be good and satisfying. One of the best-known poems is spoken by Petit, the village poet. Another poem is spoken by Ann Rutledge, a real-life girl whom young Abraham Lincoln supposedly loved.

Masters was born in Garnett, Kansas, and grew up in Lewistown, Illinois. His father's financial situation prevented Edgar from completing college. But he studied law under his father and was an attorney in Chicago from 1895 to 1920. From 1903 to 1911, he was a partner in the law firm of the famous defense attorney Clarence Darrow. In 1923, Masters settled in New York City. Masters's autobiography, *Across Spoon River,* appeared in 1936. Bonnie Costello

Masters and Johnson, two American researchers, made important contributions to the understanding of human sexual behavior. William Howell Masters (1915-2001), a physician, and his research associate, Virginia Eshelman Johnson (1925-), pioneered in the scientific study of sexual arousal and the treatment of sexual problems.

Masters began the sex research program at Washington University in St. Louis in 1954, and Johnson joined him in 1957. At that time, scientists knew little about the body's physiological responses to sexual stimulation. Masters and Johnson used motion pictures and special instruments to record such responses in men and women who volunteered to engage in sexual activity.

Masters and Johnson wrote a summary of their findings called *Human Sexual Response* (1966). This book was written in technical language for physicians and other health scientists, but it became a best seller. The research of Masters and Johnson created great controversy. Their critics called them immoral and accused them of dehumanizing sex.

In 1964, Masters and Johnson established the Reproductive Biology Research Foundation (now called the Masters and Johnson Institute) in St. Louis, Missouri. This clinic treats couples with sexual problems, trains other therapists, and conducts further research.

Masters and Johnson also wrote *Human Sexual Inadequacy* (1970), *The Pleasure Bond* (1975), and *Homosexuality in Perspective* (1979). Masters received his M.D. from the University of Rochester School of Medicine and Dentistry. Johnson began as a research assistant in the sex research project. Masters and Johnson were married in 1971. They divorced in 1993. Martin Weisberg

Masterson, Bat (1853-1921), was a famous frontiersman and peace officer in the American West. As a young man, Masterson became known as a brave buffalo hunter and Indian fighter. As a lawman, he was viewed as a cold-blooded gunfighter, but that reputation was untrue.

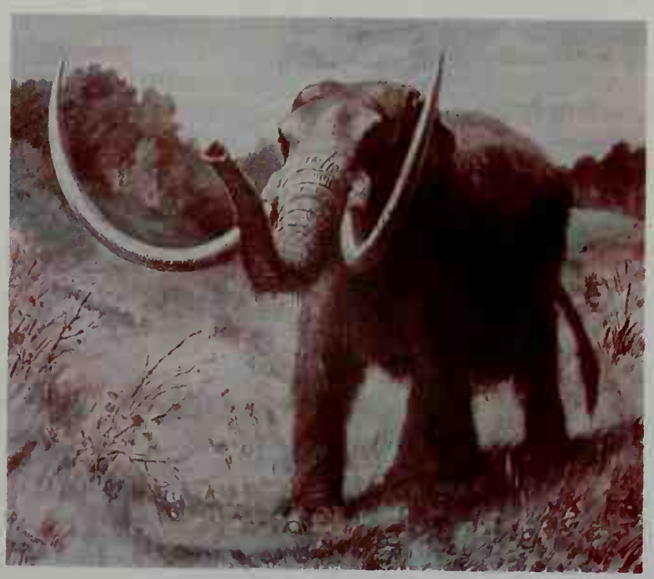
Masterson began his career as a peace officer in 1876, when he became a deputy marshal in Dodge City, Kansas, county seat of Ford County. From 1878 to 1880, he was sheriff of Ford County. In 1881, he helped his friend Wyatt Earp, a deputy United States marshal in Tombstone, Arizona, enforce the law there. Masterson served as city marshal of Trinidad, Colorado, in 1882. At times, he earned his living as a gambler. Masterson managed a gambling house in Creede, Colorado, in 1892.

Bartholomew Masterson was born in Henryville, Quebec. He later called himself William Barclay Masterson. In 1902, he moved to New York City, where he became a sportswriter for the *New York Morning Telegraph* and an authority on boxing. Odie B. Faulk

Mastic is a resin drawn from *Pistacia lentiscus,* a tree or shrub native to the Mediterranean region. Mastic was once used as a protective dressing for wounds. Today, it is used to make fine varnishes for artwork.

The term *mastic* also refers to a group of adhesive

compounds used to fasten floor, ceiling, and wall tiles. Such mastics are usually applied in thick layers with a knife or with such tools as *trowels* or *spatulas,* which have a broad, flat blade. Lewis T. Hendricks



See also **Resin.**

Mastication, *MAS tuh KAY shuhn,* is the first process in food digestion. It involves chewing or breaking the food into small pieces by grinding with the teeth. Mastication mixes the food with saliva, which reacts chemically with the food and also gives it a pasty texture. Saliva contains enzymes, including *ptyalin,* or *amylase,* which digests cooked starches into sugars; and *lipase,* which digests fats. It also contains a slimy *mucus* that lubricates food so it can be swallowed. In addition, saliva contains *bicarbonate of soda* and other salts that buffer the acids or alkalis found in some foods and drinks. Poor mastication causes overworking of digestive organs and indigestion. See also **Digestive system; Indigestion.** André Dubois

Mastiff, *MAS tihf,* also called Old English mastiff, is a large, short-haired breed of dog developed in the Middle East during ancient times. Mastiffs have been bred in England for more than 2,000 years. The breed possesses a muscular body and a large head with a short muzzle. It has apricot or brownish coloring, with darker coloring on the ears and muzzle and around the eyes. Males reach about 30 inches (76 centimeters) high at the shoulder. See also **Bullmastiff; Dog** (picture: Working dogs); **Great Dane.** Critically reviewed by the American Kennel Club

Mastodon, *MAS tuh dahn,* was an animal much like the elephant. It is now extinct. Mastodons first lived in North Africa about 40 million years ago. They spread to Asia, Europe, and the rest of Africa. Mastodons reached America about 14 million years ago and lived there until about 10,000 years ago.

Mastodons were related to another group of prehistoric elephantlike animals called *four-tuskers.* Mastodons and four-tuskers were stockier than, and not as tall as, elephants or mammoths. Early species had tusks in both jaws. Some of the later species lost the lower tusks. Others developed great, flat lower tusks. These species are called *shovel-tuskers.* The mastodon's teeth were up to 3 inches (7.5 centimeters) wide and 6 inches (15 centimeters) long. Each tooth had four to six cross-rows of heavy enamel cones, which the mastodon used to grind plants it ate. Michael R. Voorhies

Painting by Charles R. Knight, © American Museum of Natural History

The mastodon is a prehistoric relative of the modern elephant. Mastodons lived in Africa, Asia, Europe, and North America.

Scientific classification. Mastodons belong to the mastodon family, Mammutidae. The scientific name of the American mastodon is *Mammut americanum.*

See also **Mammoth; Prehistoric animal** (The age of mammals).

Mastoid, *MAS toyd,* is one of the five parts of the temporal bone of the skull. It lies at the side of the skull, just behind the ear. The name *mastoid* means *nipple-shaped.* This name describes the bottom of the mastoid, which extends downward, forming the *mastoid process.* The mastoid process may be felt as the hard area just behind and below the ear.

The mastoid process is porous, like a sponge. The *pores,* or hollow spaces, are called the *mastoid cells.* They vary greatly in size and number in different individuals. They connect with a larger, irregularly shaped cavity called the *tympanic antrum,* or *cavity.* This cavity opens into the middle ear. The mucous membrane of the middle ear extends into the tympanic antrum and the mastoid cells. Infections of the middle ear spread through these connections and may infect the mastoid cells. Doctors call this infection *mastoiditis.*

Mastoiditis may be serious because the mastoid cells are close to the organs of hearing, to important nerves, to the covering of the brain, and to the jugular vein. A mastoid infection may spread to any of these.

Mastoiditis may result from blowing the nose the wrong way. If both nostrils are held closed when a person blows his or her nose, germs may be forced from the throat into the *Eustachian tubes.* These tubes link the back of the nose with the middle ear. Antibiotics have cured mastoiditis, but severe cases may require surgery (see **Antibiotic**). Charles W. Cummings

Masur, *mah ZOOR,* **Kurt** (1927-), is a German conductor who specializes in music of the classical and romantic periods. Masur served as musical director of the New York Philharmonic from 1991 to 2002.

Masur began his career conducting operas. He was musical director of East Berlin's Komische Oper from 1960 to 1964. He was chief conductor of the Dresden Philharmonic from 1967 to 1972 and has directed the Leipzig Gewandhaus Orchestra since 1970. Masur has toured widely with the Leipzig orchestra, and has been a guest conductor in orchestras worldwide. He made his American debut with the Cleveland Orchestra in 1974 and first conducted the New York Philharmonic in 1981.

Masur was born on July 18, 1927, in Brieg, Germany (now Brzeg, Poland). He studied piano and cello at the National Music School in Breslau, Germany (now Wroclaw, Poland), from 1942 to 1944. From 1946 to 1948, he studied piano, composition, and conducting at the Leipzig Conservatory. In 2000, Masur became principal conductor of the London Philharmonic. John H. Baron

Mata Hari, *MAH tuh HAH ree* (1876-1917), was a Dutch dancer whom the French convicted of spying for the Germans during World War I (1914-1918). She admitted receiving money from the Germans but denied passing them any secrets. French intelligence also employed her in 1916. When the French realized she was working as a double agent, she was arrested and executed on Oct. 15,

UPI/Bettmann

Mata Hari was a popular exotic dancer in Europe before World War I. The French accused her of spying for the Germans during the war, and she was executed in 1917.

1917. Mata Hari was born Margaretha Geertruida Zelle in Leeuwarden, the Netherlands, on Aug. 7, 1876. Her dancing career began in Paris in 1905, and she became popular across Europe before World War I.

Julie Wheelwright

Matador. See Bullfighting.

Matanuska Valley, *mat uh NOOS kuh,* lies in south-central Alaska, near Anchorage. High mountains to the north and warm ocean currents from Cook Inlet to the south help prevent extreme temperatures in the valley.

The Matanuska Valley was the site of a large-scale farming experiment begun by the federal government during the Great Depression. In 1935, the government established 202 economically depressed families from Michigan, Minnesota, and Wisconsin on farms in the Matanuska Valley. Dairy farming, poultry raising, and vegetable growing became important activities there. The valley became the chief center of Alaska's relatively small agricultural activity. The farm operations began to decline in the 1960's, when reliable air freight service from farming areas outside Alaska was established. Today, the Matanuska Valley remains Alaska's chief farming center. However, many of the valley's residents are now employed in jobs in Anchorage. Claus-M. Naske

Match is a slender piece of cardboard or wood with a tip made of a chemical mixture that burns easily. Matches are used to produce fire. When the tip is rubbed against a rough or specially prepared surface, the chemicals burst into flame and ignite the match.

India is the world's leading producer of matches. Brazil, South Africa, and the United States also have large match industries. Matches, which were invented in the early 1800's, provided the first cheap, convenient method of producing fire.

Kinds of matches

The matches we use today are of two chief types, the strike-anywhere match and the safety match.

Strike-anywhere matches will light when drawn across any rough surface. They are wooden matches with heads of two colors, usually red and white. The white tip, called the *eye,* contains the firing substance. It is made chiefly of a chemical preparation, sesquisulfide of phosphorus. The rest of the bulblike head will not fire if struck but will burn after the flaming eye sets it afire. It is larger around than the eye. This protects the matches from setting fire to each other by friction when they are packed into a box. When the match is lighted, the paraffin in which the matchstick had been dipped carries the flame from the head to the wood part.

Safety matches can be lighted only by striking them across a special surface, usually on the side of the box in which they are contained. The match head is made of a substance containing chlorate of potash. The striking surface is made of a compound of red phosphorus and sand. *Book* matches are a type of safety match made of paper and bound into a folding paper cover. The striking surface is on the outside back of the cover.

Matches can be dangerous

Many disastrous fires and hundreds of deaths have been caused by the careless use of matches. All kinds of matches should be stored where children cannot reach them. Strike-anywhere matches should be placed out of the reach of mice. Rats or mice can set off matches by gnawing at the striking heads. A match should not be thrown away until the flame is out. Even then, it should be placed in a metal or other fire-resistant container.

How matches are made

Wooden matches are made by complex automatic machines that can manufacture and package more than a million matches an hour. First, a machine cuts *splints* (matchsticks) from thin strips of poplar wood. The splints are processed through an *anti-afterglow* solution, which prevents embers from forming after a match is blown out. Then the splints are dried and put into a matchmaking machine.

The matchmaking machine puts the splints into small holes in a belt of metal plates. As the belt fills up with splints, it dips them into a series of chemicals. The splints are first dipped into paraffin, which provides a base that carries the flame from the match head to the wood. The belt also passes the splints through a chemical mixture that forms the bulbs and eyes of the

Combs of matches are loaded into a booking machine, which cuts the combs to the proper size and staples them into matchbook covers. Workers then pack the matchbooks into boxes.

Popular Culture Library, Bowling Green University

A matchbook collection may include covers designed for a variety of purposes, including advertising and the observance of an important public event.

matches. The heads may also receive a final chemical coating that protects them from moisture in the air. The finished matches are then punched from their plates, counted, and boxed in one automatic operation.

Book matches are made by two machines from rolls of heavy paper called *paperboard* that has been treated with an anti-afterglow solution. The first machine, called a *match machine,* cuts the paperboard into *combs* (strips). Each comb is divided into from 60 to 120 smaller strips. These smaller strips eventually become matches. The machine dips the combs into paraffin and then dips the tips of the combs into the match-head solution.

Next, the combs are loaded into a *booking,* or *stitching,* machine. This machine cuts the combs into the size of an individual matchbook. It also fits them into printed covers. Finally, the machine staples the combs and the covers together to form the finished matchbooks, and workers pack the matchbooks into boxes.

Collecting matchbook covers

Collecting matchbook covers is an interesting and enjoyable hobby shared by thousands of persons. Match hobbyists collect covers from places they visit, trade covers with other collectors, and even buy rare or unusual covers from hobby shops or through advertisements in hobby magazines. Some match covers have become valuable because of their rarity.

Matchbook collectors are called *phillumenists,* which means *lovers of light.* They often form clubs to help them trade covers and meet fellow hobbyists. The clubs hold meetings and conduct contests that award prizes to the best collections. Several clubs are organized on a nationwide basis.

Because of the great variety of matchbook covers, collectors classify them in order to store or display them more easily. Collectors often specialize in certain kinds, such as covers from hotels, railroads, and government organizations. Covers can also be classified by size. Most collectors prefer covers that have not been used. However, collectors will often keep a used cover until they can find an unused one to replace it in their collections.

Collectors usually store covers in albums which they buy from hobby shops or make themselves. A matchbook album should have slots to hold the covers. A cover that is pasted in an album loses its value.

History

Early fire-making devices were developed as scientists learned of chemical reactions that produced fire. In 1780, a group of French chemists invented the *phosphoric candle,* or *ethereal match,* a sealed glass tube containing a twist of paper. The paper was tipped with a form of phosphorus that burned upon exposure to oxygen. When a person broke the tube, air ignited the phosphorus. This and other early fire-producing devices were dangerous because of the poisonous fumes and extreme flammability of phosphorus.

The first matches resembling those of today appeared in 1827, when John Walker, an English pharmacist, began to make and sell *congreves.* A congreve was a splint 3 inches (8 centimeters) long, tipped with antimony sulfide, chlorate of potash, gum arabic, and starch. A person lit one by drawing it through a fold of sand-

paper. The match burst into flame with a series of small explosions that showered the user with sparks.

Charles Sauria, a French chemistry student, produced the first strike-anywhere match in the early 1830's. The match tip included phosphorus. Alonzo D. Phillips of Springfield, Mass., patented the first phosphorus matches in the United States in 1836. He made the matches by hand and sold them from door to door.

Neither Sauria nor Phillips knew that fumes from their phosphorus matches could cause a deadly disease called necrosis of the jaw, or *phossy jaw*. But after match factories began to operate during the mid-1800's, a number of workers who were exposed to phosphorus fumes died from the disease. As the match industry grew, the threat of widespread necrosis became alarming. In 1900, the Diamond Match Company purchased a French patent for matches with a striking head of sesquisulfide of phosphorus, a nonpoisonous compound. But the French formula would not work in the United States because of the difference in climate.

In 1910, as a result of the spread of necrosis, the United States placed such a high tax on phosphorus matches that the match industry faced extinction. In 1911, William A. Fairburn, a young engineer, solved the problem by adapting the French formula for sesquisulfide of phosphorus to the climate of the United States. The threat of necrosis ended.

The first safety matches were invented by Gustave E. Pasch, a Swedish chemist, in 1844. John Lundstrom, a Swedish manufacturer, began to produce them in large quantities in 1852.

The match industry centered in Sweden for many years. In the early 1900's, Ivar Kreuger, a Swedish promoter, formed the Swedish Match Company, a giant international match empire that owned factories, forests, and mines. The company operated match factories in about 40 countries and made most of the world's matches. The stock market crash of 1929 weakened Kreuger's influence, and he committed suicide in 1932. But the Swedish Match Company survived the crash and operated successfully under new management.

The invention of book matches. Joshua Pusey, a Philadelphia attorney, patented the first book matches in 1892. He called them *flexible matches*. Pusey made his matches in packages of 50. The striking surface was on the inside cover, dangerously near the heads of the matches. Because of this, book matches did not become popular until World War I (1914-1918). By that time, the Diamond Match Company had purchased Pusey's patent and made book matches safe and usable.

During World War II (1939-1945), when the United States Army had to fight the Japanese in areas where long rainy seasons prevailed, the match industry was called upon to produce a waterproof match. In 1943, Raymond D. Cady, a chemist with the Diamond Match Company, produced a formula which protected wooden matches so well that they would light after eight hours under water. This waterproof match is coated with a water- and heat-resistant substance. The substance does not interfere with the creation of enough friction to light the match. Mark C. Bean

See also **Fire** (Methods of starting fires).

Mate is the title of a merchant marine officer or naval petty officer. The term *mate* comes from an Old English word meaning *comrade* or *companion*. On merchant ships, the first mate is second in command. In the U.S. Navy, mates serve under warrant officers.

Maté, *MAH tay,* also called *Paraguay tea,* is a drink made from the dried leaves and shoots of a plant that grows in South America. People make the tea by pouring boiling water over the leaves and stems. Maté has a large amount of caffeine and produces a stimulating effect. The maté plant has dark green leaves 3 to 6 inches (8 to 15 centimeters) long, small greenish-white flowers,

WORLD BOOK illustration by John D. Dawson

The maté plant is the source of a South American tea. The tea is made by pouring boiling water over the leaves and stems.

and small, dark red fruits. Maté growing is a large industry in Paraguay, Argentina, and southern Brazil, where drinking maté is an important part of the culture. Exporters also ship maté to other countries in South America. Maté is sometimes called *yerba maté*.

Scientific classification. The maté plant is in the family Aquifoliaceae. Its scientific name is *Ilex paraguariensis*.

Alwyn H. Gentry

Materialism is a philosophical position that states that everything is material, or a state of matter. The word comes from the Latin *materia,* meaning *matter*. Materialists particularly deny that the human self is a spiritual—or in any way nonmaterial—entity. They interpret beliefs, thoughts, desires, sensations, and other mental states as properties of material systems. Materialism is often considered a "scientific" philosophy because it is closely associated with the view that everything that occurs can be explained by scientific laws—perhaps even by the laws of physics alone.

The Greek philosophers Leucippus and Democritus developed an early form of materialism called *atomism* in the 400's B.C. They believed that invisible, indivisible material particles, called *atoms,* of various sizes and shapes make up everything that exists. According to atomism, the mind itself is made up of small, round, material atoms. Later atomists included the Greek philosopher Epicurus and the Roman poet Lucretius.

The growth of Christianity, with its emphasis on spiri-

tual concerns, led to a decline in materialism for many centuries. Materialism reemerged as a significant intellectual force during the rise of modern science in the 1600's. In France, Pierre Gassendi, a philosopher and scientist, revived some of the doctrines of ancient atomism. The English philosopher Thomas Hobbes developed an uncompromisingly materialist philosophy. In addition, the French philosophers Denis Diderot and Julien de la Mettrie were among the best-known materialists of the 1700's.

A version of materialism known as *dialectical materialism* emerged in the late 1800's with the works of the German philosopher Karl Marx and the German social scientist Friedrich Engels. The German philosopher G. W. F. Hegel had used the term *dialectic* to indicate a necessary transition from one phase of the world or society or thought to another phase. This transition occurs as a result of inadequacies or "contradictions" in the earlier phase. Hegel identified dialectical processes with the development of reason or spirit, but Marx and Engels combined the notion of dialectic with the view that the forces underlying historical development are always material. Marx and Engels particularly believed that economic factors determine social structure and change. Dialectical materialism provides the philosophical basis for Communism, a political and economic movement that shaped much of history from the early 1900's to the 1990's.

Since the 1950's, many scientifically oriented philosophers have defended materialist positions in *metaphysics,* a branch of philosophy that is concerned with the basic nature of reality (see **Metaphysics**). These philosophers uphold materialist positions independent of any political ideology or theory of social development. Margaret D. Wilson

See also **Atomism; Democritus; Marx, Karl.**

Materials are types of matter in solid form from which people can make objects. Materials belong to two groups: *natural materials* and *extracted materials.* Natural materials, which include stone, wood, and wool, are used much as they occur in nature. Extracted materials, such as plastics, *alloys* (metal mixtures), and ceramics, are created by processing various natural substances.

Manufacturers determine which material to use for a given product by evaluating the *properties* (qualities) of materials. For example stainless steel, an *alloy* (mixture) of steel and chromium, resists heat and *corrosion* (rust and other chemical damage). It thus makes a good material for saucepans, *prosthetic* (artificial) body parts, and parts for missiles.

Some properties can be linked with a material's *macrostructure* (structure visible to the unaided eye). For example, the long, parallel fibers of wood give this material relatively strong resistance to a force applied along the *grain* (direction of the fibers), but relatively weak resistance to a force applied at a right angle to the grain. Other properties are explained by a material's *microstructure* (structure that can be seen only through a microscope). The low density of wood is due to the open structure of its cells. At the most basic level, the properties of materials are determined by *chemical bonds,* forces that attract atoms to one another and hold them together.

Materials scientists study how the structure of materials relates to their properties. A large part of the scientists' work involves experimentation. For example, they alter the microstructure of a material, then determine how these changes affect the properties. Materials engineers, who work in much the same way, develop new materials for use in commercial products.

Materials scientists and engineers have developed a wide variety of *engineered materials.* These materials include strong but lightweight *composite materials* made up of reinforcing materials embedded in a continuous solid body called a *matrix.* For example, carbon fibers within a matrix of adhesive resin are used to make tennis rackets and parts for aircraft. Embedding sensors and *actuators* (synthetic muscles) in composite materials results in sophisticated *smart materials.* These materials can alter their shape or operation in response to changes in conditions.

Properties of materials

Scientists group the properties of materials according to various functions that must be performed by objects made of the materials. For example, *mechanical properties* are critical in a material for a part that must resist strong mechanical forces, such as a beam of a bridge. Most properties of materials fall into six groups: (1) mechanical, (2) chemical, (3) electrical, (4) magnetic, (5) thermal, and (6) optical.

Mechanical properties are critical in a wide variety of structures and objects—from houses and space vehicles to chairs and toothbrushes. Some of the most important mechanical properties are (1) stiffness, (2) yield stress, (3) toughness, (4) strength, (5) creep, and (6) fatigue resistance.

Stiffness measures how much a material *deflects* (stretches) when subjected to a mechanical force. For example, the amount of stretch of an elastic band or the *deflection* (bend) of a shelf when a heavy book is placed on it both depend on the material's stiffness.

Yield stress measures how much force per unit area must be exerted on a material for it to permanently *deform* (change its shape). Materials that deform easily—that is, those that have a low yield stress—are generally not desirable for most purposes.

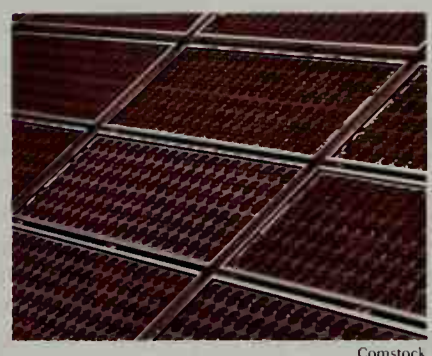
Toughness measures a material's resistance to cracking. The tougher a material, the greater the stress necessary to break that material near the tip, or end, of a crack.

Strength measures the greatest force a material can withstand without breaking. A material's strength depends on many factors, including its toughness and its shape.

Creep is a measure of a material's resistance to gradual deformation under a constant force at a constant temperature. Temperature may affect how much a material creeps—that is, deforms under stress. For example, some metals creep more readily at high temperatures than at low temperatures.

Fatigue strength measures the resistance of a material to a force of varying magnitude. A material used to make gears must have a high resistance to fatigue because the force applied to each gear tooth varies with time as a gear rotates.

Chemical properties include *resistance to corrosion* and *catalytic properties.* Resistance to corrosion meas-



Uses of materials **A variety of materials** are used in different products. Basic types of materials range from wood, which has been used for thousands of years, to composite materials, which are still under development. These photos show products made of several materials.

ures how well a material holds up to chemical attack by the environment. Catalytic properties measure the ability of a material to function as a *catalyst,* a substance that sets off or speeds up a chemical reaction without being changed by the reaction. Automobile pollution-control devices called *catalytic converters* are made partly of metals that reduce pollution by causing certain chemical reactions.

Electrical properties are important in products designed either to *conduct* (carry) or block the flow of electric current. *Electrical resistance* is a measure of the energy lost when a current passes through a material. The lower the resistance, the lower the loss of energy. Copper and other materials that have low resistance are good conductors. *Dielectric strength* describes a material's response to an electric field. It is used to evaluate how well a material can act as an *insulator* (nonconductor). A material's dielectric strength is the highest voltage difference a given thickness of the material can withstand before a current passes through it.

Magnetic properties indicate a material's response to a *magnetic field*—the region around a magnet or a conductor where the force of magnetism can be felt. *Magnetic susceptibility* is a measure of how well a material can be magnetized by an external magnetic field. A material is *ferromagnetic* if a magnetic field remains inside the material after the external magnetic field has been removed. The object composed of this material then becomes a permanent magnet.

Thermal properties reflect a material's response to heat. *Thermal conductivity* is a measure of how well a material conducts heat. Pots and pans are best made of materials that have a high thermal conductivity so they can efficiently and evenly transfer heat to food. *Heat capacity* measures a material's ability to contain heat. This property can be important in insulation materials.

Coefficient of thermal expansion indicates the increase in length of materials as they heat up. This is an important property to consider, for example, when building a telescope to orbit Earth. There is no air in outer space to equalize temperatures. Therefore, a spot on a telescope that is exposed to direct sunlight becomes much hotter than one not so exposed. If the telescope were made of material with a high coefficient of thermal expansion, its hot parts would expand much more than its cold parts, causing the telescope to warp.

Optical properties indicate how a material responds to light. The *refraction index* of a material indicates the degree to which the material changes the direction of a beam of light going through it. Manufacturers of eyeglasses use materials with a high refraction index because the higher the index is, the thinner the lenses can be made. These manufacturers must also consider *optical absorption,* a measure of how much light a material absorbs. The lower the optical absorption, the more transparent the material.

Natural materials

Natural materials generally are used as they are found, except for being cleaned, cut, or processed in a simple way. Natural materials include stone and biological materials.

Stone. Certain types of rock are extremely strong and hard, and they can be used as building stone. There are

two types of building stone: *crushed stone* and *dimension stone.* Crushed stone is mixed with tarlike substances, such as asphalt, to make paving material. It is also mixed with portland cement and sand to make concrete. Common crushed stone includes limestone and granite. Dimension stone is used for finishing and decorating buildings. Common building stones include granite, limestone, marble, sandstone, and slate.

Biological materials are substances that develop as part of a plant or animal. Plant materials include wood and such fibers as cotton and jute. Animal materials include leather and such fibers as wool and silk.

Wood is a valuable biological material because of its strength, toughness, and low density. These properties make wood an excellent material for thousands of products, including houses, sailboats, furniture, baseball bats, and railroad ties. In addition, wood serves as a raw material for a wide variety of products, including paper, rayon, and charcoal.

Plant fibers used in their natural state include cotton, flax, and jute. Many plant fibers are flexible and can be spun into yarn. Cotton cloth is soft, absorbs moisture well, and is comfortable to wear. Flax is a strong fiber made from the stems of flax plants. It is made into linen fabric and other products, including thread and rope. Jute is a long, soft fiber that can be spun into coarse, strong threads. Jute products include cloth for wrapping bales of raw cotton.

Leather is a tough, flexible material made from the skin of animals. It is strong and durable. Leather can be made as flexible as cloth or as stiff as wood. Leather products range from shoes, belts, and gloves to baseballs, basketballs, and footballs. A soft leather known as *suede* serves as a clothing material.

Animal fibers include fur, wool, and silk. The fibers in fur and wool trap air. Thus they insulate against heat and cold, and so these materials are used for clothing. Silk is the strongest natural fiber. Manufacturers unwind strands of silk from silkworm cocoons and make yarn for clothing and decorative fabrics.

Extracted materials

An extracted material is created through processes that expend a great deal of energy or alter the microstructure of the substances used to make the material. Extracted materials include ceramics, metals and their alloys, plastics, rubber, composite materials, smart materials, and semiconductors.

Ceramics include such everyday materials as brick, cement, glass, and porcelain. These materials are made from mineral compounds called *silicates,* including clay, feldspar, silica, and talc.

The properties of ceramics make them useful in a number of ways. Exposure to acids, gases, salts, and water generally does not corrode ceramics. This freedom from corrosion makes ceramics an excellent material for dinnerware and for bathroom fixtures. Such ceramics as bricks and concrete are used in construction because of their low price and their resistance to crushing. The high dielectric strength of ceramics suits them for use as insulators for electric power lines. Their high melting points make them useful as materials for cookware. The transparency and strength of glass make it an obvious choice for applications ranging from windows to precision lenses for microscopes.

Certain advanced ceramics have an unusual property known as *superconductivity.* At extremely low temperatures, these materials conduct electric current with no resistance. But these ceramics, like many others, are brittle. Engineers are working to reduce the brittleness so that these ceramics can be used commercially.

Metals and alloys can be easily shaped to create products. They are strong and are good conductors of heat and electric current. A majority of metals are not used in their pure form because they are too soft. Instead, they are used as ingredients in alloys. One exception is copper, which is used in its pure form in electrical wiring.

Iron and steel are the chief metals used in construction and to make manufactured goods. Steel is an alloy of iron and carbon, as are the materials called *cast iron* and *wrought iron.* The addition of other elements gives various kinds of steel different properties. For example, stainless steel, which contains at least 12 percent chromium, resists corrosion better than any other kind of steel. Nickel increases the hardness of steel. Tungsten makes steel more resistant to heat.

Plastics are synthetic materials made up primarily of long chains of molecules called *polymers.* There are two basic types of plastics: (1) thermosetting plastics, also called *thermosets,* and (2) thermoplastics.

Thermosets can be heated and set only once. They cannot be remelted or reshaped. Because they are highly resistant to heat, thermosets are used for electrical parts, insulation foam, oven gaskets, and appliance handles. Other objects made of thermosets include luggage and parts for automobile bodies.

Thermoplastics can be melted and reshaped. Thermoplastics are used much more widely than thermosets because they are easier to process and require less time to set. Common thermoplastic products include bottles, carpet fibers, computer housings, and garden hoses.

Rubber is made up of *elastomers,* polymers that stretch easily to several times their length and then return to their original shape. This property is known as *elasticity.* Rubber's elasticity, its ability to hold air and keep out water, and its toughness make it an important material. Rubber is used in tires; gaskets and other mechanical products; and boots, raincoats, and other waterproof clothing. Natural rubber comes from the juice of a tree. Synthetic rubber is made from petroleum.

Composite materials are solid substances made up of two distinctly different classes of materials, one embedded within the other. The embedded material is typically a load-bearing *reinforcement,* such as fibers. The surrounding material is a low-strength unifying material, such as an epoxy resin. This material, called a *matrix,* gives the composite its shape. Engineers design the macrostructure of composite materials to create unique properties that satisfy requirements for specific commercial applications. They do this by carefully selecting the form, type, and arrangement of the reinforcement, and the appropriate matrix.

One common type of composite material, fiberglass-reinforced plastic, is used for automobile bodies, yacht hulls, fishing rods, and furniture. Another fibrous composite is plastic reinforced with carbon fibers. This material is used for bicycle frames, medical devices, and

An experimental *aerogel* material is an excellent insulator of heat. A researcher holds one side of a piece of aerogel comfortably with his bare hand, though the other side is heated to 1768 °F (964 °C).

parts for high-speed industrial machinery.

Smart materials, also called *intelligent materials,* are a class of synthetic materials that can respond automatically to changing external conditions to maintain a stable structure or to perform different functions. Some structures made from smart materials can monitor and repair themselves.

Smart materials include *piezoelectric* plates or films. These materials produce electrical impulses in response to pressure, and they expand and contract when electric current is applied. *Shape-memory alloys* take on a different shape at each of two different temperatures. The most sophisticated smart materials have networks of interconnected sensors and tiny computers embedded in them. A sophisticated aircraft wing incorporating smart materials could counteract vibration that might otherwise result in poor aerodynamic behavior.

Semiconductors are materials that conduct electric current better than insulators, but not as well as conductors, at room temperature. Extremely pure crystals of semiconductor material *doped* (combined) with small, precisely controlled amounts of other substances can perform a large number of electronic functions. Such crystals, usually of silicon, are the building blocks of computer chips.

The role of bonds

Wide differences in the properties of certain kinds of materials are a result of differences in *bonds*—forces that attract atoms and molecules to one another and hold them together. *Chemical bonds* hold atoms together through the transfer or sharing of *electrons,* the negatively charged particles that whirl about the positively charged nucleus of an atom (see **Atom**). Weaker forces called *physical bonds* hold molecules together in a group.

Chemical bonds are *ionic, covalent,* or *metallic.* Ionic bonds are created by the transfer of electrons from one atom to one or more other atoms. In covalent bonding, two or more atoms share pairs of electrons. A shared pair consists of one electron from each of two atoms. In metallic bonding, all the atoms in a metal crystal share electrons. The shared electrons are free to move throughout the crystal. This movement creates a "sea" of negative electrons that surrounds and holds together the metal nuclei.

Physical bonds, also called *van der Waals forces,* hold molecules together in a group. Van der Waals forces are electrical forces caused by an interaction between charges of neighboring molecules. They are much weaker than chemical bonds because no transfer or sharing of electrons occurs.

One way bonding determines properties involves electrical resistance. Ordinary ceramics are held together chiefly by covalent and ionic bonds. These bonds hold electrons near individual atoms. Much energy is therefore needed to make these electrons flow as electric current. Ceramics thus have a high resistance. By contrast, metals are held together by metallic bonds. Because many atoms share electrons, the electrons can circulate easily within the material. Metals therefore conduct current and have a low electrical resistance.

Bonding also determines important properties of polymers. These materials are made of long molecules featuring chainlike structures of carbon atoms linked by covalent bonds. In some polymers, covalent bonds also join chains to one another. These polymers are said to be *cross-linked.*

When a thermoset is heated for the first time, its chains cross-link. When the material is heated again, the cross-links do not break, so the material does not melt. A thermoplastic, however, does not form cross-links. When it is heated, its physical bonds become so weak that the chains can slide past one another. The material therefore melts. Brian S. Thompson

The uses of mathematics are wide-ranging. For example, mathematics may be used to solve scientific problems, design industrial projects, and carry out business transactions.

Mathematics

Mathematics is one of the most useful and fascinating divisions of human knowledge. It includes many topics of study. For this reason, the term *mathematics* is difficult to define. It comes from a Greek word meaning "inclined to learn."

Most of the basic mathematics taught in school involves the study of number, quantity, form, and relations. *Arithmetic,* for example, concerns problems with numbers. *Algebra* involves solving *equations* (mathematical statements of equality) in which letters represent unknown quantities. *Geometry* concerns the properties and relationships of figures in space.

The most important skills in mathematics are careful analysis and clear reasoning. These skills can help us solve some of the deepest puzzles we must face. Mathematics is based upon logic. Starting from widely accepted statements, mathematicians use logic to draw conclusions and develop mathematical systems.

The importance of mathematics

The work of mathematicians may be divided into *pure mathematics* and *applied mathematics.* Pure mathematics seeks to advance mathematical knowledge for its own sake rather than for any immediate practical use. For example, a mathematician may create a system of geometry for an imaginary world where objects have more dimensions than just length, width, and depth. Applied mathematics seeks to develop mathematical techniques for use in science and other fields.

Joseph W. Dauben, the contributor of this article, is Professor of History and History of Science at Herbert H. Lehman College and the Graduate Center of the City University of New York. He is the editor of The History of Mathematics from Antiquity to the Present. *The drawings in this article were prepared for* World Book *by Zorica Dabich and Garri Budynsky.*

The boundary between pure and applied mathematics is not always clear. Ideas developed in pure mathematics often have practical applications, and work in applied mathematics frequently leads to research in pure mathematics.

Nearly every part of our lives involves mathematics. It has played an essential role in the development of modern *technology*—the tools, materials, techniques, and sources of power that make our lives and work easier.

In everyday life, we use mathematics for such simple tasks as telling time from a clock or counting our change after making a purchase. We also use mathematics for such complex tasks as making up a household budget or figuring our income tax. Cooking, driving, gardening, sewing, and many other common activities involve mathematical calculations. Mathematics is also part of many games, hobbies, and sports.

In science. Mathematics is an essential part of nearly all scientific study. It helps scientists design experiments and analyze data. Scientists use mathematical formulas to express their findings precisely and to make predictions based on these findings.

The physical sciences, such as astronomy, chemistry, and physics, rely heavily on mathematics. Such social sciences as economics, psychology, and sociology also depend greatly on statistics and other kinds of mathematics. For example, some economists create mathematical models of economic systems. These models are sets of formulas used to predict how a change in one part of the economy might affect other parts.

In industry. Mathematics helps industries design, develop, and test products and manufacturing processes. Mathematics is necessary in designing bridges, buildings, dams, highways, tunnels, and other architectural and engineering projects.

In business, mathematics is used in transactions that involve buying and selling. Businesses need mathematics to keep records of such things as inventory and employees' hours and wages. Bankers use mathematics to handle and invest funds. Mathematics helps insurance

companies calculate risks and compute the rates charged for insurance coverage.

Branches of mathematics

Mathematics has many branches. They may differ in the types of problems involved and in the practical application of their results. However, mathematicians working in different branches often use many of the same basic concepts and operations. This section discusses several of the main kinds of mathematics.

Arithmetic includes the study of whole numbers, fractions and decimals, and the operations of addition, subtraction, multiplication, and division. It forms the foundation for other kinds of mathematics by providing such basic skills as counting and grouping objects, and measuring and comparing quantities. See **Addition; Arithmetic; Division; Multiplication; Subtraction.**

Algebra, unlike arithmetic, is not limited to work with specific numbers. Algebra involves solving problems with equations in which letters, such as x and y, stand for unknown quantities. Algebraic operations also use negative numbers and *imaginary numbers* (the square roots of negative numbers). See **Algebra; Square root** (Square roots of negative numbers).

Geometry is concerned with the properties and relationships of figures in space. *Plane geometry* deals with squares, circles, and other figures that lie on a plane. *Solid geometry* involves such figures as cubes and spheres, which have three dimensions.

About 300 B.C., Euclid, a Greek mathematician, stated the definitions and assumptions of the system of geometry that describes the world as we usually experience it. But later mathematicians developed alternative systems of geometry that rejected Euclid's assumption about the nature of parallel lines. Such *non-Euclidean geometries* have proved useful, for example, in the theory of relativity—one of the outstanding achievements of scientific thought. See **Geometry.**

Analytic geometry and trigonometry. Analytic geometry relates algebra and geometry. It provides a way to represent an algebraic equation as a line or curve on a graph. Analytic geometry also makes it possible to write equations that exactly describe many curves. For example, the equation $x = y^2$ describes a curve called a *parabola.*

Trigonometry is used widely by astronomers, navigators, and surveyors to calculate angles and distances when direct measurement is impossible. It deals with the relations between the sides and angles of triangles, especially *right triangles* (triangles that have a 90° angle). Certain relations between the lengths of two sides of a right triangle are called *trigonometric ratios.* Using trigonometric ratios, a person can calculate the unknown angles and lengths in a triangle from the known angles and lengths. Formulas involving trigonometric ratios describe curves that physicists and engineers use to analyze the behavior of heat, light, sound, and other natural phenomena. See **Trigonometry.**

Calculus and analysis have many practical uses in engineering, physics, and other sciences. Calculus provides a way of solving many problems that involve motion or changing quantities. *Differential calculus* seeks to determine the rate at which a varying quantity changes. It is used to calculate the slope of a curve and the changing speed of a bullet. *Integral calculus* tries to find a quantity when the rate at which it is changing is known. It is used to calculate the area of a curved figure or the amount of work done by a varying force. Unlike algebra, calculus includes operations with *infinitesimals* (quantities that are not zero but are smaller than any assignable quantity). See **Calculus.**

Analysis involves various mathematical operations with infinite quantities and infinitesimals. It includes the study of *infinite series,* sequences of numbers or algebraic expressions that go on indefinitely. The concept of infinite series has important applications in such areas as the study of heat and of vibrating strings. See **Series** (Working with infinite series).

Probability and statistics. Probability is the mathematical study of the likelihood of events. It is used to determine the chances that an uncertain event may occur. For example, using probability, a person can calculate the chances that three tossed coins will all turn up heads. See **Probability.**

Statistics is the branch of mathematics concerned with the collection and analysis of large bodies of data to identify trends and overall patterns. Statistics relies heavily on probability. Statistical methods provide information to government, business, and science. For example, physicists use statistics to study the behavior of the many molecules in a sample of gas. See **Statistics.**

Set theory and logic. Set theory deals with the nature and relations of *sets.* A set is a collection of items, which may be numbers, ideas, or objects. The study of sets is important in investigating most basic mathematical concepts. See **Set theory.**

In the field of logic—the branch of philosophy that deals with the rules of correct reasoning—mathematicians have developed *symbolic logic.* Symbolic logic is a formal system of reasoning that uses mathematical symbols and methods. Mathematicians have devised various systems of symbolic logic that have been important in the development of computers.

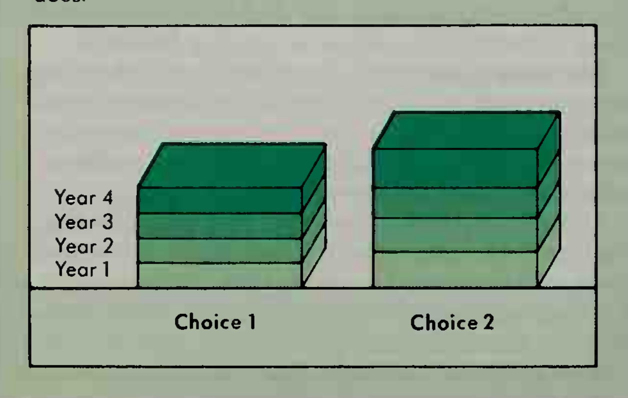
History

Early civilization. Prehistoric people probably first counted with their fingers. They also had various methods for recording such quantities as the number of animals in a herd or the days since the full moon. To represent such amounts, they used a corresponding number of pebbles, knots in a cord, or marks on wood, bone, or stone. They also learned to use regular shapes when they molded pottery or carved arrowheads.

By about 3000 B.C., mathematicians of ancient Egypt used a *decimal system* (a system of counting in groups of 10) without place values. The Egyptians pioneered in geometry, developing formulas for finding the area and volume of simple figures. Egyptian mathematics had many practical applications, ranging from surveying fields after the annual floods to making the intricate calculations necessary to build the pyramids.

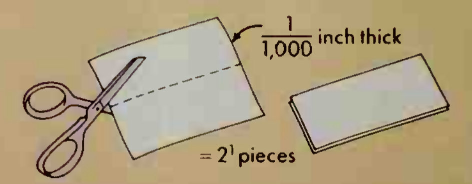
By 2100 B.C., the people of ancient Babylonia had developed a *sexagesimal system*—a system based on groups of 60. Today, we use such a system to measure time in hours, minutes, and seconds. Historians do not know exactly how the Babylonian system developed. They think it may have arisen from the use of weights and measures based on groups of 60. The system had

(Text continued on page 306)



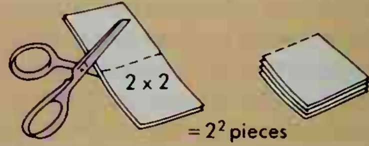
The following problems all require the use of important mathematical skills, including careful analysis of situations and reasoning to reach solutions. Try to solve the problems and then compare your work with the solutions provided.

1. ***Which salary would you choose?*** **Your boss offers you one of two salary arrangements. "Which would you prefer," she asks, "a salary starting at $16,000 a year with an $800 increase each year, or one starting at $8,000 for a half year with a $200 increase each half year?" Which choice offers the higher salary?**



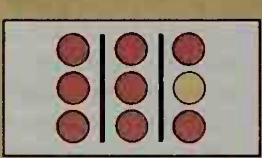
Make a chart to show the two choices of salary over a number of years.

Year	Choice 1	Choice 2
First year	$16,000	$8,000 + $8,200 = $16,200
Second year	$16,800	$8,400 + $8,600 = $17,000
Third year	$17,600	$8,800 + $9,000 = $17,800
Fourth year	$18,400	$9,200 + $9,400 = $18,600

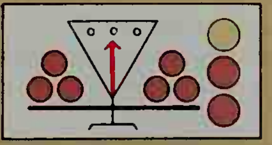


Choice 2 gives you $200 more each year than choice 1 does.

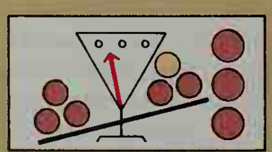
3. ***A little pile of paper.*** **Imagine that you have a huge sheet of paper only $\frac{1}{1,000}$ inch (0.025 millimeter) thick. You cut the sheet in half and put one piece of paper on top of the other.**



You cut these two pieces in half and put the resulting four pieces together in a pile. Then you cut the pile of four pieces in half and put the resulting eight pieces in a pile. Suppose that you continue in this manner until you have cut the pile in half 50 times, each time piling up the resulting pieces. How high do you think the final pile would be?

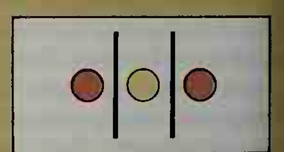


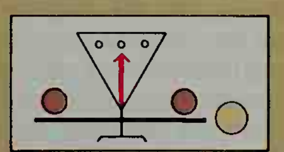
After the first cut, you have 2 pieces. After the second cut, you have 2 × 2, or 2^2 pieces. Following the third cut, you have 2 × 2 × 2, or 2^3 pieces. Therefore, after the 50th cut, you should have 2^{50} pieces. Two multiplied by itself 50 times is about 1,126,000,000,000,000. Because there are 1,000 pieces of paper to the inch, divide by 1,000 to find the number of inches in the pile. Next, divide the number of inches by 12 to find the number of feet in the pile. Then divide the number of feet by 5,280 to find the number of miles. You may be surprised to find that the pile of paper is about 17,770,000 miles (28,600,000 kilometers) high!



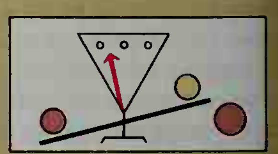
2. ***Find the counterfeit.*** **You have nine rare and valuable coins. Although they appear to be identical, you know that one is counterfeit and weighs less than the others. Using a balance scale only twice, how can you find the fake coin?**

First, divide the coins into three groups of three coins.





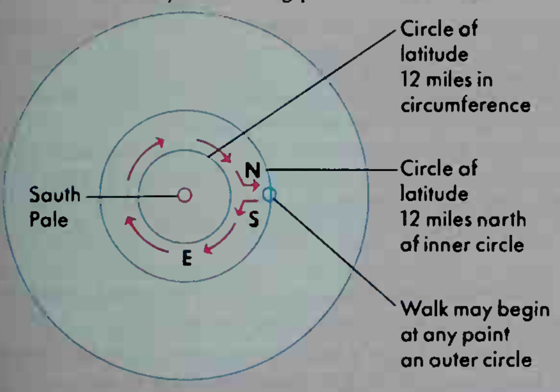
Weigh one group against another. If they balance, then the fake, or light, coin is in the group you have not weighed.



If the two groups of coins do not balance, then the fake coin is in the lighter group on the scale.

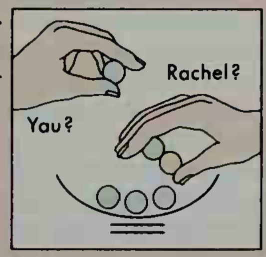
Next, take the group of three coins that contains the fake.

Weigh two coins from this group against each other. If they balance, then the coin you have not weighed is the fake.



If the two coins do not balance, then the lighter coin on the scale is the counterfeit.

4. *Where to start?* From what point or points on the earth's surface could you walk 12 miles (19 kilometers) due south, then walk 12 miles due east, then walk 12 miles due north, and find yourself back at your starting point?

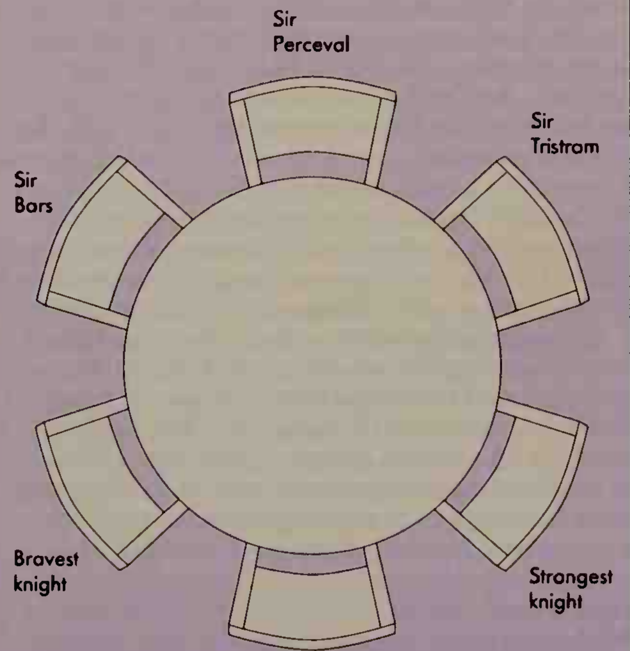


The usual answer to this old riddle is the North Pole. But the earth actually has an infinite number of points from which you could begin such a walk.

In theory, the equator forms a circle of latitude around the middle of the earth. As one goes north or south from the equator, the circumference of the circles of latitude gets progressively smaller until you reach the poles. Near the South Pole, there is a circle of latitude exactly 12 miles in circumference. Twelve miles north of this first circle is a second circle of latitude. You can start your walk at any point on this outer circle. You walk 12 miles south and find yourself on the inner circle. Then you walk 12 miles east around this circle—that is, you walk once around the earth, which is only 12 miles in circumference at this latitude. You then walk 12 miles north and arrive back at your starting point.

An infinite number of other points also can serve as your starting place. There are circles of latitude closer to the South Pole that have a circumference of 6 miles, 3 miles, 2 miles, and so forth. By starting at any point 12 miles north of any of these circles, you could take the walk described. Suppose, for example, you start 12 miles north of the circle of latitude that has a circumference of 1 mile. First you walk 12 miles south. Then you walk 12 miles east—that is, you go around the inner circle 12 times. Then, after walking north for 12 miles, you will arrive at your starting point on the outer circle.

5. *Whose turn to win?* Your friend Rachel challenges you to a game. There are six marbles in a bowl. At a turn, a player may take either one or two marbles. The player who takes the last marble wins the game. Rachel offers to let you take the first turn. If you accept, who wins?



Assume that each player will always make the best move. The winner will take the winning turn when either one or two marbles are left. Therefore, the winner will be the player who leaves the opponent three marbles. If you make the first move and take one marble, Rachel can take two—leaving three for you and winning on her next turn. If, on the first move, you take two marbles, then Rachel can take one—again leaving three for you and winning on her next move. If you accept her kind offer to take the first turn, Rachel will win the game!

6. *The Little Round Table.* Imagine that King Arthur, the legendary British ruler, commands only six knights—Sir Bors, Sir Galahad, Sir Gawain, Sir Lancelot, Sir Perceval, and Sir Tristram. According to his custom, King Arthur seats his knights around a circular table to avoid quarrels over who would occupy the seats of honor.

Each knight has an identifying characteristic. There is a strongest knight, a bravest knight, a knight in shining armor, a handsome knight, a knight who rides a white horse, and a tallest knight. Based on the following clues, who is the strongest knight? (1) The strongest knight sits across from Sir Bors, who sits to the right of Sir Perceval. (2) Sir Tristram sits across from the bravest knight, and to the right of the strongest knight. (3) The knight in shining armor sits between Sir Bors and the handsome knight, and across from the knight who rides a white horse. (4) Sir Lancelot sits to the right of the tallest knight and next to Sir Gawain.

The best way to solve this puzzle is to draw a table and six chairs, then fill in names and characteristics as the clues reveal them. The first clue tells you that the strongest knight sits across from Sir Bors, who is to the right of Sir Perceval. That gives you three positions.

The second clue says that Sir Tristram sits across from the bravest knight, and to the right of the strongest knight. That gives you two more positions.

Clue three tells you that the knight in shining armor sits between Sir Bors and the handsome knight. Two people are between Bors and someone else—the bravest knight and Sir Perceval. But the bravest knight cannot be the knight in shining armor, so Sir Perceval must be the knight in shining armor. Also, because Sir Tristram is on Sir Perceval's other side, Sir Tristram must be the handsome knight. Clue three also gives you the position of the knight on a white horse. Thus far, the only position not associated with a characteristic is that of Sir Bors, so Sir Bors must be the tallest knight.

Clue four tells you that Sir Lancelot sits to the right of the tallest knight. You know that Sir Bors is the tallest knight, so Sir Lancelot is to the right of Sir Bors. The clue also says that Sir Lancelot sits next to Sir Gawain. This leaves only one position and one name unaccounted for. So Sir Galahad is obviously the strongest knight.

important uses in astronomy, and also in commerce, because 60 can be divided easily. The Babylonians went well beyond the Egyptians in algebra and geometry.

The Greeks. Ancient Greek scholars became the first people to explore pure mathematics, apart from practical problems. They made important advances by introducing the concepts of logical deduction and proof to create a systematic theory of mathematics. According to tradition, one of the first to provide mathematical proofs based on deduction was the philosopher Thales, who worked in geometry about 600 B.C.

The Greek philosopher Pythagoras, who lived about 550 B.C., explored the nature of numbers, believing that everything could be understood in terms of whole numbers or their ratios. However, about 400 B.C., the Greeks discovered *irrational numbers* (numbers that cannot be expressed as a ratio of two whole numbers), and they recognized that Pythagorean ideas were incomplete. About 370 B.C., Eudoxus of Cnidus, a Greek astronomer, formulated a theory of proportions to resolve problems associated with irrational numbers. He also developed the *method of exhaustion,* a way of determining areas of curved figures, which foreshadowed integral calculus.

Euclid, one of the foremost Greek mathematicians, wrote the *Elements* about 300 B.C. In this book, Euclid constructs an entire system of geometry by means of abstract definitions and logical deductions. During the 200's B.C., the Greek mathematician Archimedes extended the method of exhaustion. Using a 96-sided figure to approximate a circle, he calculated a highly accurate value for *pi* (the ratio of a circle's circumference to its diameter). Ptolemy, an astronomer in Alexandria, Egypt, applied geometry and trigonometry to astronomy about A.D. 150 in a 13-part work on planetary motions. It became known as the *Almagest,* meaning *the greatest.*

Chinese mathematics originally developed to aid record keeping, land surveying, and building. By the 100's B.C., the Chinese had devised a decimal system of numbers that included fractions, zero, and negative numbers. They solved arithmetic problems with the aid of special sticks called *counting rods.* The Chinese also used these devices to solve equations—even groups of simultaneous equations in several unknowns.

Perhaps the best-known early Chinese mathematical work is the *Jiu Zhang Suan Shu (Nine Chapters on the Mathematical Art),* a handbook of practical problems that was compiled in the first two centuries B.C. In 263 A.D., the Chinese mathematician Liu Hui wrote a commentary on the book. Among Liu Hui's greatest achievements was his analysis of a mathematical statement called the Gou-Gu theorem. The theorem, known as the Pythagorean theorem in the West, describes a special relationship that exists between the sides of a right triangle. Liu Hui also calculated the value of pi more accurately than ever before. He did so by using a figure with 3,072 equal sides to approximate a circle.

Arab mathematics. Scholars in the Arab world translated and preserved the works of ancient Greek mathematicians and made their own original contributions as well. A book written about 825 by the Arab mathematician al-Khowarizmi described a numeration system developed in India. This decimal system, which used place values and zero, became known as the Hindu-Arabic numeral system. Al-Khowarizmi also wrote

Important dates in mathematics

c. 3000 B.C. The Egyptians used a system based on groups of 10 and developed basic geometry and surveying techniques.
c. 370 B.C. Eudoxus of Cnidus developed the method of exhaustion, foreshadowing integral calculus.
c. 300 B.C. Euclid constructed a system of geometry by means of logical deduction from accepted mathematical truths called *axioms.*
Mid-1100's A translation of al-Khowarizmi's book on arithmetic introduced the Hindu-Arabic numeral system to Europe.
1614 John Napier published his discovery of logarithms, an aid in simplifying calculations.
1637 René Descartes published his discovery of analytic geometry, proposing mathematics as the perfect model for reasoning.
Mid-1680's Sir Isaac Newton and Gottfried Wilhelm Leibniz published their independent discoveries of calculus.
Early 1800's Carl F. Gauss, Janos Bolyai, and Nikolai Lobachevsky separately developed non-Euclidean geometries.
Early 1820's Charles Babbage developed mechanical computing machines.
1854 George Boole published his system of symbolic logic.
Late 1800's Georg Cantor developed set theory and a mathematical theory of the infinite.
1910-1913 Alfred North Whitehead and Bertrand Russell published *Principia Mathematica,* which argues that all mathematical propositions can be derived from a few axioms.
Early 1930's Kurt Gödel showed that in any system of axioms, there are statements that cannot be proved.
Late 1950's and 1960's A new system of teaching called the *new mathematics* was introduced in the United States.
1970's and 1980's Computer-based mathematical models came into wide use in studies in business, industry, and science.

an influential book about algebra. The word *algebra* comes from the Arabic title of this book.

In the mid-1100's, a Latin translation of al-Khowarizmi's book on arithmetic introduced the Hindu-Arabic numeral system to Europe. In 1202, Leonardo Fibonacci, an Italian mathematician, published a book on algebra that helped promote this system. Hindu-Arabic numerals gradually replaced Roman numerals in Europe.

Arab astronomers of the 900's made major contributions to trigonometry. During the 1000's, an Arab physicist known as Alhazen applied geometry to optics. The Persian poet and astronomer Omar Khayyam wrote an important book on algebra about 1100. In the 1200's, Nasir al-Din al-Tusi, a Persian mathematician, created ingenious mathematical models for use in astronomy.

The Renaissance. During the 1400's and 1500's, European explorers sought new overseas trade routes, stimulating the application of mathematics to navigation and commerce. Artists created a system of mathematical perspective that gave their paintings an illusion of depth and distance. The invention of printing with movable type in the mid-1400's resulted in speedy and widespread communication of mathematical knowledge.

The Renaissance also brought major advances in pure mathematics. In a book published in 1533, a German mathematician known as Regiomontanus established trigonometry as a field separate from astronomy. French mathematician François Viète made advances in algebra in a book published in 1591.

Mathematics and the scientific revolution. By 1600, the increased use of mathematics and the growth of the experimental method were contributing to revolutionary advances in knowledge. In 1543, Nicolaus Copernicus, a Polish astronomer, published an influential book in which he argued that the sun, not the earth, is

the center of the universe. In 1614, John Napier, a Scottish mathematician, published his discovery of *logarithms,* numbers that can be used to simplify such complicated calculations as those used in astronomy. Galileo, an Italian astronomer of the late 1500's and early 1600's, found that many types of motion can be analyzed mathematically.

In 1637, French philosopher René Descartes proposed mathematics as the perfect model for reasoning. He invented analytic geometry. Another French mathematician of the 1600's, Pierre de Fermat, founded modern number theory. He and French philosopher Blaise Pascal explored probability theory. Fermat's work with infinitesimals helped lay a foundation for calculus.

The English scientist Sir Isaac Newton invented calculus in the mid-1660's. His discovery was published in 1687. Working independently, the German philosopher and mathematician Gottfried Wilhelm Leibniz also invented calculus in the mid-1670's. He published his findings in 1684 and 1686.

Developments in the 1700's. A remarkable family of Swiss mathematicians, the Bernoullis, made many contributions to mathematics during the late 1600's and the 1700's. Jakob Bernoulli did pioneering work in analytic geometry and wrote about probability theory. Jakob's brother Johann also worked in analytic geometry and in mathematical astronomy and physics. Johann's son Nicolaus helped advance probability theory. Johann's son Daniel used mathematics to study the motion of fluids and the properties of vibrating strings.

During the mid-1700's, Swiss mathematician Leonhard Euler advanced calculus by showing that the operations of differentiation and integration were opposites. Beginning in the late 1700's, French mathematician Joseph Louis Lagrange worked to develop a firmer foundation for calculus. He was suspicious of relying on assumptions from geometry and, instead, developed calculus entirely in terms of algebra.

In the 1800's, public education expanded rapidly, and mathematics became a standard part of university education. Many of the great works in mathematics of the 1800's were written as textbooks. In the 1790's and early 1800's, French mathematician Adrien Marie Legendre wrote particularly influential textbooks and did work in calculus, geometry, and number theory. Important calculus textbooks by French mathematician Augustin Louis Cauchy were published in the 1820's. Cauchy and Jean Baptiste Fourier, another French mathematician, made significant advances in mathematical physics.

Carl Friedrich Gauss, a German mathematician, proved the fundamental theorem of algebra, which states that every equation has at least one root. His work with imaginary numbers led to their increased acceptance. In the 1810's, Gauss developed a non-Euclidean geometry but did not publish his discovery. Working separately, Janos Bolyai of Hungary and Nikolai Lobachevsky of Russia also developed non-Euclidean geometries. They published their discoveries about 1830. In the mid-1800's, Georg Friedrich Bernhard Riemann of Germany developed another non-Euclidean geometry.

During the early 1800's, the works of German mathematician August Ferdinand Möbius helped develop a study in geometry that became known as *topology.* Topology explores the properties of a geometrical figure that do not change when the figure is bent or stretched.

In the late 1800's, German mathematician Karl Theodor Weierstrass worked to establish a more solid theoretical foundation for calculus. In the 1870's and 1880's, his student Georg Cantor developed set theory and a mathematical theory of the infinite.

Much exciting work in applied mathematics was done in the 1800's. In the United Kingdom, Charles Babbage developed early mechanical computing machines, and George Boole created a system of symbolic logic. During the late 1800's, French mathematician Jules Henri Poincaré contributed to probability theory, celestial mechanics, and the study of electromagnetic radiation.

Philosophies of mathematics. Many mathematicians have shown concern for the philosophical foundations of mathematics. To eliminate contradictions, some mathematicians have used logic to develop mathematics from a set of *axioms* (basic statements considered to be true). Two British philosophers and mathematicians, Alfred North Whitehead and Bertrand Russell, promoted a philosophy of mathematics called *logicism.* In their three-volume work, *Principia Mathematica* (1910-1913), they argued that all *propositions* (statements) in mathematics can be derived logically from just a few axioms.

David Hilbert, a German mathematician of the early 1900's, was a *formalist.* Formalists consider mathematics to be a purely formal system of rules. Hilbert's work led to the study of imaginary spaces with an infinite number of dimensions.

Beginning in the early 1900's, Dutch mathematician Luitzen Brouwer championed *intuitionism.* He believed people understand the laws of mathematics by *intuition* (knowledge not gained by reasoning or experience).

In the early 1930's, Austrian mathematician Kurt Gödel demonstrated that for any logical system, there are always theorems that cannot be proved either true or false by the axioms within that system. He found this to be true even of basic arithmetic.

Mathematicians made major advances in the study of abstract mathematical structures during the 1900's. One such structure is the *group.* A group is a collection of items, which may be numbers, and rules for some operation with these items, such as addition or multiplication. Group theory is useful in many areas of mathematics and such fields as subatomic physics.

Since 1939, a group of mathematicians, most of whom are French, have published an influential series of books under the pen name Nicolas Bourbaki. This series takes an abstract approach to mathematics, using axiom systems and set theory.

New areas of mathematical specialization arose during the 1900's, including systems analysis and computer science. Advances in mathematical logic have been essential to the development of electronic computers. Computers, in turn, enable mathematicians to complete long and complicated calculations quickly. Since the 1970's, computer-based mathematical models have become widely used to study weather patterns, economic relationships, and many other systems.

Other new areas of mathematical specialization in the late 1900's included *fractal geometry* and *chaos theory.* Fractal geometry deals with complex shapes called *fractals.* These shapes consist of small-scale and large-

scale structures that resemble one another. Certain fractals are also similar to natural objects, such as coastlines or branching trees. Although fractals seem irregular, they have a simple organizing principle. Chaos theory attempts to find underlying patterns in what seem to be random variations, such as changes in the weather or the stock market.

Trends in teaching mathematics. Before the 1950's, most mathematics courses in elementary, junior high, and high schools in the United States stressed the development of basic computational skills. During the late 1950's and the 1960's, *new mathematics* was introduced. New mathematics is a way of teaching mathematics that stresses understanding concepts rather than memorizing rules and performing repetitious drills. In the 1970's and 1980's, educators continued to use new mathematics, but they gave added emphasis to problem solving and computational skills.

At the college level, educators have moved away from teaching mathematics in the same way to all students. Instead, colleges and universities offer more courses in specialized applications of mathematics in such fields as economics, engineering, and physics.

Careers

A strong background in mathematics is excellent preparation for a wide variety of careers. Students who wish to study mathematics in college should take high school courses in algebra, geometry, trigonometry, and calculus, if available. These courses also are useful for study in architecture, engineering, and physics.

In college, the basic courses for a major in mathematics include advanced calculus, differential equations, abstract algebra, numerical analysis, number theory, theories of real and complex variables, probability, and statistics. Courses in logic and computer programming also are useful in preparing for many careers.

Mathematicians teach at all levels. High school mathematics teachers must have at least a bachelor's degree in mathematics. Many mathematicians with a doctor's degree teach at colleges and universities.

Large numbers of mathematicians work in business, government, or industry. Those with a bachelor's degree may find work as accountants, computer operators, and statisticians. Many people who have earned a master's or doctor's degree in mathematics conduct research for the communications, energy, manufacturing, or transportation industries. Mathematicians also work in the computer industry as programmers or as systems analysts who determine the most efficient use of a computer in any given situation. Insurance companies employ mathematicians as actuaries to calculate risks and help design policies. Joseph W. Dauben

Mather, Cotton (1663-1728), was a leading Puritan minister and theologian in colonial New England. His grandfather Richard Mather and his father, Increase Mather, were also famous colonial religious leaders.

Mather involved himself in all the affairs of New England. He wrote about 450 published works, most of them sermons. Many scholars consider him one of the first distinctly American thinkers. Mather spent most of his energy preaching on how to know and serve God. He taught that individuals must have an inward, personal experience with God to be saved, and that they must lead lives devoted to acts of goodness.

Among Mather's best-known works is the *Magnalia Christi Americana* (1702), a history of Christianity in New England in the 1600's. *Bonifacius* (1710) is a book of essays on how to be good. Mather gained fame and criticism for his support of smallpox inoculation during an epidemic in Boston in 1721. He blended his interest in science with a fascination with the supernatural, especially witchcraft and Bible prophecies about the end of the world. Some people accused him of prompting a hysteria over witches that resulted in the conviction and execution of 19 people as witches at Salem, Massachusetts, in 1692. Today most historians dispute the charge. See **Salem witchcraft trials; Witchcraft** (History).

Mather was born in Boston. His intellectual talents became evident at an early age. He graduated from Harvard College at 15. In the early 1680's, he joined his father on the staff of the Second Church in Boston, where he remained until his death. Richard W. Pointer

Mather, Increase (1639-1723), was the most influential pastor and theologian among the second generation of Puritan ministers in colonial New England. The Puritans were Protestant reformers who advocated simpler forms of worship and stricter morals. Richard Mather, his father, and his son Cotton Mather were also Puritan leaders.

Mather wrote many books and pamphlets on a wide variety of topics. He believed there was a general spiritual and moral decline in New England. He repeatedly denounced this trend in sermons. He interpreted a witchcraft scare in Salem in 1692 as God's judgment on a disobedient New England. Among Mather's most celebrated causes was opposing the more lenient standards of Congregational minister Solomon Stoddard on church membership and Holy Communion.

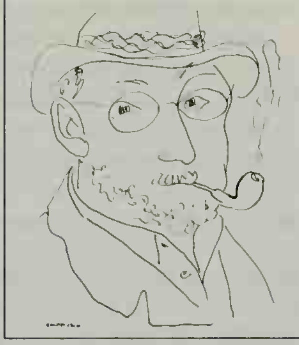
Mather was born in Dorchester, Massachusetts. In 1664, he accepted the position of teacher at the Second Church, or Old North Church, in Boston. He remained there until his death, even while serving as president of Harvard College from 1685 to 1701. His successful diplomatic efforts in England from 1688 to 1692 secured a new charter for Massachusetts. Mather's religious conservatism led to his resignation from the Harvard presidency and gained him a reputation as a staunch defender of traditional Puritan ways. Richard W. Pointer

Mather, Richard (1596-1669), was an important Puritan minister among the first generation of English settlers in the Massachusetts Bay Colony. He was the father of Increase Mather and the grandfather of Cotton Mather, two leading colonial religious leaders.

Mather was born in Lowtown, England, near Liverpool. He was an ordained minister in the Church of England from 1619 until he was suspended in 1633 because of his Puritan views (see **Puritans**). Mather chose to move with his family to Massachusetts in 1635, and a year later he became pastor of a newly founded church in Dorchester. He held that position until his death.

Mather was active in the Massachusetts colony's religious life and strongly urged that each congregation should control its own affairs. He wrote a series of essays on the subject and was a major figure in writing the *Cambridge Platform,* the Congregational Church's official rules on discipline and government, adopted in 1648. Earlier, he had aided Puritan worship by helping to compile the hymnal called the *Bay Psalm Book* (1640), the first book printed in colonial America.
Richard W. Pointer

Mathewson, Christy (1880-1925), was one of baseball's greatest right-handed pitchers. He won 373 games, 372 of them with the New York Giants from 1900 to 1916. Mathewson became the first pitcher in the 1900's to win 30 games a season three years in a row. He also pitched 20 or more victories for 12 consecutive seasons.



Christopher Mathewson was born in Factoryville, Pennsylvania. He became famous for developing a reverse curve pitch that was called a *fadeaway.* Today the pitch is known as a *screwball.* Mathewson pitched three shutouts in the 1905 World Series. In 1908, he won 37 games. Mathewson led the league in strikeouts for five seasons—1903, 1904, 1905, 1907, and 1908. He became one of the first five players elected to the National Baseball Hall of Fame in 1936. Jack Lang

Matisse, *mah TEES,* **Henri,** *ahn REE* (1869-1954), a French painter, was one of the most influential artists of the 1900's. He was the leader of the Fauves, a group of artists who painted in a style that emphasized intense color and vigorous brushstrokes. The Fauves started the first important art movement of the 1900's. Matisse was also a noted sculptor and graphic artist.

Matisse's favorite subjects included human figures, still lifes, and scenes of interiors. He believed the arrangement of colors and forms was as important as the subject matter to communicate the meaning of a painting. Although he made few entirely abstract images, he avoided detailed illusion. Instead, he used intense colors and strong lines to produce patterns and a sense of movement. These features often produce a tension with

the figurative subjects of his paintings. Matisse's works, especially those of the 1920's, have a decorative quality similar to the art of the Near and Middle East. He was one of the first European artists to be influenced by African masks and sculpture.

Ink drawing (1949) by Matisse; collection of S. Max Becker, Jr., Glencoe, Illinois

Henri Matisse

Matisse was born in Le Cateau, near Cambrai. He entered law school in 1887 but began to paint in 1890 as a pastime while recovering from an operation. In 1891, Matisse moved to Paris to study art. In the early 1890's, he painted with dark colors. But he showed the influence of the bright colors of the Impressionists in his painting *The Dinner Table* (1897).

In 1905, works by Matisse and other Fauve painters were exhibited together. The brilliant colors and bold patterns of these paintings shocked the Paris art world.

From 1907 to about 1920, Matisse painted increasingly simplified designs that reflected the influence of the French artist Paul Cézanne and of the Cubists. Matisse also did his most important work as a sculptor during this period. In his last years, Matisse created large, decorative compositions made of cut paper. From 1948 to 1951, he designed and decorated the Chapel of the Rosary in Vence, France. Nancy J. Troy

Matter is the substance of which all objects are made. Matter has many forms, all of which have a property called *inertia.* Inertia is an object's resistance to a change in its state of motion. An object that is at rest tends to remain at rest due to inertia. A moving object tends to maintain its speed and direction of movement.

Mass is a measure of inertia. An object with a relatively large mass has a higher resistance to a change in its state of motion than does an object with a relatively small mass. Thus, more force is needed to move a more massive object than to move a less massive object under the same conditions. Mass is often defined as the amount of the matter of which an object is made.

Mass is also the source of *gravitation,* a force of attraction between two objects. *Weight* is a term used in science and technology for the gravitational force between a planet or another large object and a relatively small object. At any given distance from the center of a planet, the weight of the small object is proportional to its mass: The greater the mass, the greater the weight. But as an object moves away from the planet, the gravitational force decreases. Thus, for example, a space probe launched from the earth loses weight as it flies away, though its mass remains the same.

In commercial and everyday use, the term *weight* is understood to mean mass. Thus, people weigh themselves to measure the amount of matter that makes up their bodies. This use of *weight* can cause confusion. In the United States, the scale would be marked in pounds. But the pound is used as a unit of force in science and technology. In other countries, the markings would indicate kilograms. The kilogram is the metric unit of mass.

Matter can be changed into energy and energy into matter. The mass of an object represents the energy required to create its matter. Whenever energy is taken from something, such as when an electric battery is discharged, its mass decreases. Similarly, if energy is put into a battery by charging it, its mass increases. For the amounts of energy used in everyday life, however, the changes in mass are too small to measure.

Structure of matter

Matter has structure at many levels, from groupings of galaxies so vast that light rays take hundreds of millions of years to cross them to particles so small that scientists describe them as pointlike. The solid objects that we use in everyday life consist of molecules and crystals. These structures, in turn, consist of atoms that are linked together. An atom is made up of particles called *protons, neutrons,* and *electrons.* Protons and neutrons, which carry most of the atom's mass, consist of pointlike units known as *quarks.* Each proton or neutron consists of three quarks. Massless particles called *gluons* hold the quarks together. Scientists have not yet determined whether quarks can be broken down into smaller bits. Electrons are also considered to be pointlike. Particles smaller than an atom are called *subatomic particles.*

The diameter of an atom ranges from about 0.1 to 0.5 nanometer. A nanometer is a billionth of a meter, or $\frac{1}{25,400,000}$ inch. Protons and neutrons make up the atom's nucleus, which is about ten thousand times smaller than the atom. Electrons whirl around the nucleus.

Differences in electric charge hold the atom together. Protons have a positive charge, and neutrons are electrically neutral, so the nucleus as a whole is positively charged. Electrons are negatively charged. Because opposite charges attract, an electric force tends to keep the electrons in place.

Electrons whirl around the nucleus in layers called *electron shells.* The electrons in the outermost shells are not tightly bound to the nucleus. As a result, some outer electrons can be shared by two atoms in a *chemical bond,* a linking of atoms. Molecules consist of atoms bonded in this way. Outer electrons can also jump from one atom to another, producing positive and negative *ions* (charged atoms). Ions can bond to form crystals. For example, solid sodium chloride—common table salt—is a crystal consisting of positive sodium ions and negative chloride ions.

States of matter

Since ancient times, matter has been known to exist in three states, also called *phases:* (1) solids, (2) liquids, and (3) gases. In the 1900's, scientists identified four additional states: (1) plasmas, (2) superconductors, (3) superfluids, and (4) Bose-Einstein condensates. In 2000, scientists announced that they had created quark-gluon plasmas. Matter can change from one state to another. When this occurs, the appearance of the matter may change drastically. However, the chemical composition remains the same, except in plasmas and quark-gluon plasmas. These form at such high temperatures that any chemical bonds are destroyed.

Solids, liquids, and gases occur at familiar temperatures and pressures. For example, ice is solid water. At normal atmospheric pressure—the pressure at sea level—ice melts at a temperature of 32 °F (0 °C), forming liquid water. When heat raises the temperature of the water to 212 °F (100 °C), the water boils, producing steam, a gas. The other five states of matter are found at very high or very low temperatures.

Solids tend to retain their shape, and they resist *compression* (reduction in the amount of space they occupy). Most solids consist of small crystals packed together.

Liquids assume the shape of their container and can flow freely. Like solids, liquids resist compression. The atoms or molecules of a liquid are in contact with one another but are not linked, so they can move freely past one another.

Gases expand to fill their containers, and they can be compressed fairly easily. The atoms or molecules of a gas are not in contact with one another and are always moving violently. In gases at familiar pressures and temperatures, each atom or molecule collides with others millions or billions of times per second.

Plasmas are gaslike substances in which some or all atoms have lost at least one electron, leaving a mixture of free electrons and positively charged ions. Plasmas form at temperatures of tens of thousands of degrees or higher, or through the action of an electric current. The sun and most other stars consist mainly of plasma. On earth, plasmas are found in lightning discharges and in fluorescent lights and neon signs.

Superfluids are liquids that flow without resistance. As a result, they will pass through the pores of a container. Scientists have found this phase only in helium, one of the few substances that remains a liquid within a few degrees of *absolute zero:* −459.67 °F or −273.15 °C. At absolute zero, atoms and molecules would have the least possible energy.

Superconductors are solids in which electrons move freely. Once started, an electric current in a superconductor can flow forever without the help of an external power supply. Many metals are superconductors at temperatures within a few degrees of absolute zero. Other substances superconduct at temperatures more than 100 Celsius degrees (180 Fahrenheit degrees) above absolute zero.

Bose-Einstein condensates, also known as BEC's, are clusters of millions of atoms that merge under conditions of extreme cold. BEC's can form in some gases when they are cooled to within a few billionths of a Celsius degree of absolute zero. When a BEC forms, millions of atoms stop moving in different directions at different speeds and instead act as a single atom. The condensates are named for physicists Satyendra Nath Bose of India and Albert Einstein of Germany, who proposed the possibility of BEC's in the 1920's.

Quark-gluon plasmas consist of quarks moving freely in a "sea" of gluons. This state of matter dominated the universe during its first 10 one-millionths of a second. At that time, the temperature was more than 1 million million °C. Today, quark-gluon plasmas have only a fleeting existence in nature. Scientists create quark-gluon plasmas by colliding heavy atomic nuclei in a machine called a *particle accelerator.* The machine accelerates the nuclei to almost the speed of light. Quark-gluon plasmas occur when collisions compress nuclei to a fraction of their normal volume.

Unusual forms of matter

Scientists have discovered an unusual form of matter called *antimatter. Dark matter,* which may be fundamentally different from ordinary matter, apparently also exists. Physicists do not know what it is made of, however.

Antimatter. Physicists can convert energy into matter with particle accelerators. When subatomic particles collide at high speeds, they create new particles. Whenever particles of matter are created, an equal number of particles of antimatter are also made. Antimatter particles are equal in mass to the equivalent particles of matter but opposite in electric charge and certain other properties. For example, *positrons,* which are positively charged, are the antimatter equivalents of electrons. If a matter particle meets an equivalent antimatter particle, the two particles destroy each other. Both particles are converted into energy.

Antimatter particles are rare and last only until they encounter matter and are destroyed. There appear to be no large concentrations of antimatter in the universe.

Dark matter. More than 99 percent of the visible universe is made up of the two lightest kinds of atoms, hydrogen and helium. It appears, however, that most of the matter in the universe is invisible dark matter. Scientists have detected dark matter only through the influ-

ence of its gravitational force on the motions of visible matter. Many scientists believe that dark matter is composed of undiscovered particles. Robert H. March

Matterhorn, *MAT uhr HAWRN,* is a famous mountain peak in the Pennine Alps. It rises 14,692 feet (4,478 meters) on the boundary between the *canton* (state) of Valais in southern Switzerland and the Piedmont region of Italy (see **Switzerland** [political map]). The peak rises like a pyramid from the surrounding mountain base. Snow always covers the upper slopes. Many climbers have scaled the peak's steep sides. The first person to make the challenging climb to the top of the Matterhorn was Edward Whymper in 1865. See also **Alps; Mountain** (diagram: Major mountains); **Seven Natural Wonders of the World; Switzerland** (picture). Howell C. Lloyd

Matthew, Saint, was one of the 12 apostles of Jesus Christ. The Gospel of Matthew states that Matthew was working as a tax collector when he was called to follow Jesus. But the Gospels of Mark and Luke state that the tax collector's name was *Levi.* Some scholars have suggested that Levi was Matthew's second name. They also suggest that all of the Gospels refer to the same person.

Matthew has traditionally been regarded as the author of the first Gospel, perhaps written in Hebrew or Aramaic. Many modern scholars, however, believe that he was not the author and that this Gospel was originally written in Greek. According to tradition, Matthew preached in Africa and Persia, where he was martyred.

Matthew's feast day is celebrated on September 21 in the Roman Catholic Church. The Eastern Orthodox Churches celebrate his feast day on November 16.

Richard A. Edwards

See also **Apostles; Gospels.**

Matthias, *muh THY uhs,* **Saint,** was an early Christian. He is mentioned once in the New Testament as a follower of Jesus who was chosen by the remaining 11 apostles to replace Judas Iscariot (Acts 1:15-26). According to later tradition, Matthias traveled in Judea, Turkey, and Ethiopia as a missionary. His feast day is May 14 in the West and August 9 in the Eastern Orthodox Churches.

Richard A. Edwards

Matzeliger, Jan Ernst (1852-1889), invented a machine that revolutionized the shoe industry. He made the first shoe-lasting machine, which shaped and fastened the leather over the sole of a shoe. This process, which previously had been done by hand, led to the mass production of shoes and greatly reduced their price.

Matzeliger, a black, was born in Paramaribo, Dutch Guiana (now Suriname). As a boy, he worked in a government machine shop there. In 1873, Matzeliger settled in Philadelphia and worked as a cobbler. In 1877, he took a job in a shoe factory in Lynn, Massachusetts.

Matzeliger completed his shoe-lasting machine in 1882 and patented it in 1883. He did not have enough money to produce and sell the machine, and so in 1885 he sold the patent to a company in Lynn. This company later became the United Shoe Machinery Company.

Matzeliger died of tuberculosis at the age of 37. He shared only partly in the great profits that resulted from his invention. Raymond W. Smock

Mau Mau, *MOW mow,* was a secret movement that included Africans who wanted to end European colonial rule in Kenya. Most who took the oath of unity were Kikuyu people who lived in overcrowded areas. The movement began in the late 1940's. British forces started a drive to wipe out the movement after a series of murders and other terrorist attacks by the Mau Mau started in 1952. Jomo Kenyatta, who later became the president of Kenya, was convicted of leading the movement and was held in a remote area until 1961. When the fighting ended in 1956, about 11,500 Kikuyu had been killed. About 2,000 other Africans, 95 Europeans, and 29 Asians lost their lives supporting the colonial government.

Carl G. Rosberg

See also **Kenya** (Opposition to the British).

Mauchly, *MAWK lee,* **John William** (1907-1980), was a key figure in the development of the computer. He was the chief consultant on the project that built ENIAC (*E*lectronic *N*umerical *I*ntegrator *A*nd *C*omputer), one of the world's first general-purpose electronic digital computers. The computer was developed for the United States Department of War. In 1943, the department selected Mauchly, then an engineering professor at the University of Pennsylvania, to serve on the project. It chose J. Presper Eckert, Jr., a graduate student at the university, to be the chief engineer. Mauchly, Eckert, and their team completed ENIAC in late 1945. They demonstrated it publicly in 1946. That same year, Eckert and Mauchly founded the Electronic Control Company (later renamed the Eckert-Mauchly Computer Corporation).

In 1948, the Federal Bureau of Investigation (FBI) began to investigate accusations, later proved false, that Mauchly had Communist connections. Mauchly's military security clearance was taken away in 1950 but fully restored in 1958. During the period that Mauchly was denied security clearance, his company lost business because it could not secure certain military contracts.

Remington Rand, Inc. (now part of Unisys Corporation), purchased Eckert-Mauchly Computer in 1950. At Remington Rand, Eckert and Mauchly completed their construction of UNIVAC (*UNIV*ersal *A*utomatic *C*omputer), the first commercially successful computer.

Mauchly was born in Cincinnati, Ohio. He received a doctorate in physics in 1932 from Johns Hopkins University. Paul N. Edwards

See also **Computer** (The first electronic computers; picture: ENIAC); **Eckert, J. Presper, Jr.**

Maugham, *mawm,* **W. Somerset** (1874-1965), was a fiction and drama writer who became one of the most popular British authors of the 1900's. But his reputation stood far higher with the public than with critics.

Maugham usually wrote in a detached, ironic style, yet he often showed sympathy for his characters. His semiautobiographical novel *Of Human Bondage* (1915) established his position as a serious writer. Considered his finest work, it is a realistic story of a medical student's bondage to his lameness and his love for an unappreciative woman. *Cakes and Ale* (1930) is a comic satire about an English author. Maugham based his novel *The Moon and Sixpence* (1919) on the life of the painter Paul Gauguin. Maugham's experiences in the British

secret service during World War I (1914-1918) provided the background for a group of related stories published as *Ashenden* (1928).

Maugham's *Collected Short Stories* was published in four volumes in 1977 and 1978. *The Summing Up* (1938) and *A Writer's Notebook* (1949) are the direct, personal observations of a professional writer.

Maugham wrote many sophisticated plays, beginning with *Lady Frederick* (1907). His most popular comedies include *The Circle* (1921) and *The Constant Wife* (1927).

William Somerset Maugham was born in Paris, the son of a British embassy official. He studied medicine at the request of his family, but he never practiced after completing his internship. Sharon Bassett

Maui. See Hawaii (The islands).

Mauldin, *MAWL dihn,* **Bill** (1921-), is an American editorial cartoonist. He became famous during World War II (1939-1945) for his drawings of U.S. Army life in *The Stars and Stripes,* the armed forces newspaper. The main characters in these cartoons, two American GI's named Willie and Joe, often showed the resentment of enlisted soldiers toward officers. Mauldin won the Pulitzer Prize for cartooning in 1945 and 1959.

William Henry Mauldin was born in Mountain Park, New Mexico. He served in the Army from 1940 to 1945. After his release from the Army, he worked for several years as a cartoonist for United Features Syndicate. In 1958, Mauldin became editorial cartoonist for the *St. Louis Post-Dispatch,* where he became known for his satirical wit and liberal views. His cartoons are syndicated to about 200 newspapers. Collections of his cartoons include *Up Front* (1945), *Back Home* (1947), *The Brass Ring* (1971), and *Mud and Guts* (1978). Michael Emery

"Beautiful view! Is there one for the enlisted men?"

A typical Bill Mauldin cartoon drawn during World War II lampoons officers. Mauldin's cartoons accurately pictured the favorite gripes and the plight of the common soldier in the war.

Mauna Kea, *MOW nuh KAY uh,* is a volcano on the island of Hawaii. Its peak rises 13,796 feet (4,205 meters) above sea level and 33,476 feet (10,203 meters) above the base of the mountain on the floor of the Pacific Ocean. Its rise from base to peak is the greatest in the world. This distance is about 4,440 feet (1,350 meters) longer than the rise from sea level to the peak of Mount Everest. The name Mauna Kea means *white mountain.* See also Mountain (diagram: Major mountains).

Mauna Loa, *MOW nuh LOH uh,* a volcanic mountain on the island of Hawaii, rises 13,677 feet (4,169 meters) above sea level in Hawaii Volcanoes National Park (see Hawaii [physical map]). It is the world's largest volcano. At the top is Mokuaweoweo, a crater. Kilauea volcano lies on the southeastern slope.

Mauna Loa's longest eruption lasted 18 months in 1855-1856. Most of the lava produced by eruptions comes from the sides of the mountain, not from the peak crater. In 1926, lava destroyed a fishing village. Parts of other villages were buried in 1950. A 1984 eruption sent lava flowing to within 4 miles (6.4 kilometers) of the city of Hilo. Lyndon Wester

Maundy Thursday, *MAWN dee,* also called Holy Thursday, is observed on the Thursday during Holy Week in the Christian calendar. It comes three days before Easter. Maundy Thursday celebrates two events of Jesus Christ's last week on earth—washing the feet of His disciples and sharing the Last Supper with them.

The name *Maundy* probably comes from a Latin word that means *mandate* or *commandment.* It refers to Jesus's commandment that His disciples wash one another's feet as He had washed theirs. The commandment is linked with His words to the disciples (John 13:34): "A new commandment I give unto you, That ye love one another."

Special services on Maundy Thursday may include a reenactment of the washing of feet and the administering of Communion. Both acts help visibly remind Christians of their share in Christ's love. David G. Truemper

Mauriac, *maw RYAK,* **François,** *frahn SWAH* (1885-1970), a French author, won the 1952 Nobel Prize for literature. His novels are set among middle-class people in his native Bordeaux. The attitudes toward sin and love expressed in his fiction reflect his Roman Catholic faith. Mauriac's novels explore the mysteries of human existence, the nature of destiny, and human guilt before a judging though forgiving God. His stories are noted for their psychology and beautiful language. Mauriac's major novels include *The Kiss to the Leper* (1922), *Thérèse Desqueyroux* (1927), *Vipers Tangle* (1932), and *The Frontenac Mystery* (1933).

In 1934, Mauriac began to write essays on his view of life and literature for the newspaper *Le Figaro.* These es-

says have been republished periodically in collections called *Journals.* Mauriac also wrote several plays, including *Asmodée* (1938) and *Le Feu sur la terre* (1951). His poetry was collected in *Le Sang d'Atys* (1940). His biographies include two studies of Christ, *Life of Jesus* (1936) and *The Son of Man* (1958).

Mauriac was elected to the French Academy in 1933. Claude Mauriac, his son, is also a well-known novelist.

Elaine D. Cancalon

Mauritania, *MAWR ih TAY nee uh,* is a country in western Africa. It stretches eastward from the Atlantic coast into the Sahara. Arabic-speaking people called Moors make up most of the population. Black Africans form a large minority group. Almost all of the people of Mauritania are Muslims.

Mauritania was once a colony in French West Africa. It became independent in 1960. Its name in French is République Islamique de Mauritanie (Islamic Republic of Mauritania). Nouakchott is the capital and largest city.

Government. A president serves as head of state of Mauritania, and a prime minister as head of government. The president manages the nation's foreign affairs. The prime minister, with the help of the Council of Ministers (cabinet), directs the day-to-day operations of the government. The legislature consists of a Senate with 56 members and a National Assembly with 79 members. The people elect the president and the members of the legislature. The president appoints the prime minister, who then appoints members to the Council of Ministers.

Mauritania is divided into 12 regions and 1 district for purposes of local government. The capital makes up the district. The Republican Democratic and Social Party (PRDS) is the largest political party in Mauritania.

People. The majority of people are Moors, descendants of Arabs and Berbers. Most Moors speak Arabic. Some lead a nomadic life, living in tents and moving over the desert with their cattle in search of water holes and pastureland. Others live in cities or villages, or in rural areas where they farm.

The Moors are divided into two main groups, *white Moors* and *black Moors.* The terms *white* and *black* refer to social status and family lineage rather than to skin color. The white Moors, who have the higher status, are in turn divided into two groups, the warriors and the *marabout* (saintly) classes. Before French rule, the warriors were a nobility who kept black slaves. Other classes served the warriors, whose chief occupation was fighting. The marabout have always raised cattle, sheep, and other livestock. Traditionally, leading marabout families were a learned class who advised the warriors.

About a third of Mauritania's people are black Africans belonging to any of several ethnic groups. Many are farmers who live in villages along the Sénégal River. Their circular houses, with walls made of sun-dried mud brick, stand along narrow, twisting village pathways. The largest black ethnic group is the Toucouleur. Other groups include the Fulbe (also called *Fulani),* the Soninké, the Wolof, and the Banbara. The blacks were the first to gain a modern education, and many hold jobs in government and as teachers.

Mauritania has two main languages, Arabic and French. Both have been used extensively in government and education. But black ethnic groups also speak their own languages. Serious disputes over language use have broken out over the years. In 1991, Arabic became the country's official language. At the same time, Arabic and three black languages—Poular, Soninké, and Wolof—were recognized as national languages. Both Moors and blacks seek to promote their own interests in language and other matters.

Only about 10 percent of Mauritania's children attend primary school, and an even smaller percentage attend high school. The country's first university, the University of Nouakchott, opened in 1983.

Land. An imaginary line drawn between Nouakchott on the coast and Néma in the southeast divides Mauritania into two major land regions. The Sahara covers most of the area north of the Nouakchott-Néma line. It is broken only by rocky plateaus and a few oases.

The small part of the country south of the line contains two fertile areas—a narrow plain along the Sénégal River and a *savanna* (grassland with scattered trees) in

Facts in brief

Capital: Nouakchott.

Official language: Arabic. *National languages*—Arabic, Poular, Soninké, Wolof.

Area: 395,956 mi² (1,025,520 km²). *Greatest distances*—north-south, 800 mi (1,287 km); east-west, 780 mi (1,255 km). *Coastline*—414 mi (666 km).

Elevation: *Highest*—Kediet Ijill, 3,002 ft (915 m) above sea level. *Lowest*—sea level along the coast.

Population: *Estimated 2002 population*—2,814,000; density, 7 per mi² (3 per km²); distribution, 54 percent urban, 46 percent rural. *1988 census*—1,864,660.

Chief products: *Agriculture*—dates, gum arabic, livestock (cattle, sheep, goats), rice, sorghum. *Manufacturing*—fish processing, petroleum refining. *Mining*—iron ore.

Flag: The flag is green and has a yellow star and crescent in the center. The green color and the star and crescent stand for Mauritania's ties to Islam and the rest of northern Africa. The yellow stands for the country's ties to nations south of the Sahara. See **Flag** (picture: Flags of Africa).

Money: *Basic unit*—ouguiya. Five khoums equal one ouguiya.

Wolfgang Kaehler

Mauritanians gather in Nouadhibou, the nation's chief port. Arabic-speaking people called Moors make up most of the country's population. Black Africans form a large minority group.

the southeast. Farmers raise millet, rice, and other crops on the plain. Herders raise livestock in the savanna area. Most of the people live in the south.

Mauritania's climate is hot, but temperatures vary greatly. Desert temperatures may fall from over 100 °F (38 °C) during the day to 45 °F (7 °C) at night. The average monthly temperatures at Nouadhibou vary from a 91 °F (33 °C) high in September to a 54 °F (12 °C) low in January. There is little rain in the north. Southern Mauritania receives over 20 inches (51 centimeters) of rain a year.

Economy. Mauritania's economy is based on agriculture, and about 63 percent of the people are farmers and livestock herders. Chief food crops include dates, rice, and sorghum. Gum arabic, used to make mucilage, and livestock on the hoof are important exports. Rich fishing waters lie off the coast.

High-grade iron ore deposits near Fdérik are Mauritania's most important mineral resource. The ore is exported chiefly to Germany, Italy, and the United Kingdom. It provides a large part of the government's revenue.

Incomes in Mauritania are low, and most workers make only enough to provide for their families. The government depends on aid from other countries—chiefly France—to balance its budget. Poor communications and transportation hinder economic development.

Mauritania's railroad links Zouirât and Akjoujt with Nouadhibou, the chief port. Less than a fifth of the nation's 5,500 miles (8,900 kilometers) of roads are paved.

History. From the A.D. 300's to the 1500's, areas of Mauritania were part of three great west African empires—Ghana, Mali, and Songhai. In the early 1900's, archaeologists identified ruins in southeastern Mauritania as part of Kumbi Saleh, the capital of the Ghana Empire. See **Ghana Empire; Mali Empire; Songhai Empire.**

The Portuguese landed in Mauritania in the 1400's, but continuous European contact did not begin until the 1600's. From the 1600's to the 1800's, France, the Netherlands, and the United Kingdom competed for the Mauritanian gum arabic trade.

France began to occupy Mauritania in 1902 and set up a protectorate there in 1903. Xavier Coppolani became the first governor. Modern Mauritania is largely the result of Coppolani's work in promoting Mauritanian identity separate from neighboring states and of his successors' ability to extend French rule over the country. Mauritania became a French colony in 1920.

In 1946, Mauritania became a territory in the French Union. It became a self-governing republic in the French Community in 1958. Mokhtar Ould Daddah was elected prime minister in 1959. Supported by many Moorish leaders and educated black leaders, he favored independence and close ties with west African countries. On Nov. 28, 1960, Mauritania became fully independent. Morocco claimed that Mauritania was historically Moroccan territory and did not recognize its independence. Some of Ould Daddah's opponents fled to Morocco and worked to unite the two countries. But Morocco recognized Mauritania's independence in 1970.

In 1961, Mauritania adopted a constitution that set up a presidential system of government. Ould Daddah, elected the first president, merged Mauritania's four political parties into a single party, the Mauritanian People's Party. A 1965 constitutional amendment officially made Mauritania a one-party state.

In 1976, Spain gave up control of its overseas province of Spanish Sahara, and Mauritania and Morocco took over its administration. This area—which borders Mauritania, Morocco, and Algeria—is now called Western Sahara. Mauritania claimed the southern part of the area, and Morocco claimed the northern part. But Algeria and an organization of people of Western Sahara called the Polisario Front opposed the claims. Fighting broke out between Polisario Front troops and troops from Mauritania and Morocco. In 1978, military leaders overthrew Ould Daddah and took control of the government. The following year, Mauritania gave up its claim to Western Sahara and ended its role in the fighting.

In the early 1980's, a severe drought caused widespread food shortages and losses of livestock in Mauritania. The drought became more severe in the mid-1980's, causing many people to move from rural areas to cities. The cities became overpopulated. Farm production fell sharply.

In 1992, Mauritania established a multiparty democracy. Maawiya Ould Sid Ahmed Taya, an army colonel who had been president of the military government, was elected president. Opposition parties boycotted the

Mauritania

WORLD BOOK maps

1992 parliamentary elections. In elections held in 1996, members of parties other than the progovernment Republic Democratic and Social Party gained representation in the national legislature. Kenneth J. Perkins

Mauritius, *maw RIHSH uhs,* is an island nation in the Indian Ocean. Its chief island, also called Mauritius, lies about 500 miles (800 kilometers) east of Madagascar and about 2,450 miles (3,943 kilometers) southwest of India. Geographically, Mauritius is considered part of Africa. Overpopulation is one of the country's problems.

Sugar cane fields cover about half of the island. Bare, black volcanic peaks tower over the sugar cane fields.

The Dutch claimed Mauritius in 1598. Later, France and then the United Kingdom ruled the island. Mauritius gained its independence from the United Kingdom in 1968. It remained a member of the Commonwealth of Nations. Port Louis is the capital and leading port.

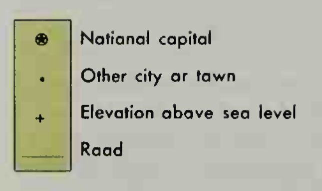
Government. Mauritius is a republic. A 70-member National Assembly makes the country's laws. The people elect most of the Assembly members. The Assembly elects a president, who serves as head of state. A prime minister, who is the country's most powerful government official, heads the operations of the government. The prime minister is elected by the National Assembly and officially appointed by the president.

Elections for the National Assembly are held at least once every five years. Each voter casts three votes. The voters elect three Assembly members from each of the island's 20 districts. The small island of Rodrigues chooses two Assembly members. To guarantee fair representation for minority groups, an electoral supervisory commission chooses eight more members from among unsuccessful candidates. They choose four members from minorities that do not have enough representatives in the Assembly in proportion to their numbers in the population. They choose the other four on the basis of minority groups and political party.

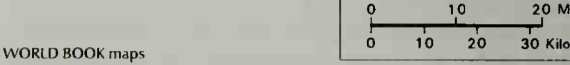
Councils govern the country's cities and towns. The council members are elected by the people.

People. The people of Mauritius are descendants of European settlers, African slaves, Chinese traders, and Indian laborers and traders. Almost 70 percent of the people are Indians, and almost 30 percent are people of European and African or European and Indian ancestry called *Creoles.* The rest are Chinese or Europeans. Most Europeans are of French descent.

About half the people live in villages and other rural areas, and half live in towns. Most Europeans live in towns. Most men wear Western-style clothes. Indian women wear the *sari* (a straight piece of cloth draped around the body).



English is the official language. But most people speak *Creole,* a French dialect. Some Indians speak one or more of six Indian dialects. The Chinese speak two Chinese dialects. Most Europeans speak French. More than 50 percent of the people are Hindus. About 30 percent are Christians, and about 17 percent are Muslims.



Primary and secondary education are free. Almost all children in Mauritius attend primary school. Mauritius has an agricultural college, a teachers' training college, and a university.

Land. Mauritius covers 788 square miles (2,040 square kilometers). The country consists of the island of

Mauritius

WORLD BOOK maps

Mauritius, with an area of 720 square miles (1,865 square kilometers), and several other islands. The other islands include Rodrigues, about 350 miles (563 kilometers) east of Mauritius; Agalega, two small islands about 580 miles (933 kilometers) north of Mauritius; and the Cargados Carajos Shoals, about 250 miles (402 kilometers) north. Mauritius also claims the Chagos Archipelago, an island group about 1,300 miles (2,100 kilometers) northeast of the island of Mauritius. The archipelago makes up the British Indian Ocean Territory and is controlled by the United Kingdom. The archipelago includes the island of Diego Garcia, the site of a U.S. naval base.

The island of Mauritius was formed by volcanoes that left the land covered with rocks and a thick layer of lava. A misty plateau in the center of the island rises 2,200 feet (671 meters) above sea level. This area may receive up to 200 inches (510 centimeters) of rain a year. In the north, the plateau slopes to the sea. However, it drops sharply to the southern and western coasts. Dry regions that receive only about 35 inches (89 centimeters) of rain a year lie in the southwest. Coral reefs surround all but the southern part of the island.

Summer lasts from November to April, and the temperatures then average about 79 °F (26 °C). Southeast winds bring rains to the plateau. Sometimes cyclones strike the island. Winter lasts from June to October. Temperatures then average about 72 °F (22 °C).

Economy. Mauritius has one of Africa's strongest

Facts in brief

Capital: Port Louis.
Official language: English.
Area: 788 mi² (2,040 km²). *Greatest length*—38 mi (61 km). *Greatest width*—29 mi (47 km). *Coastline*—100 mi (161 km).
Elevation: *Highest*—2,711 ft (826 m). *Lowest*—sea level.
Population: *Estimated 2002 population*—1,177,000; population density, 1,494 per mi² (577 per km²); distribution, 57 percent rural, 43 percent urban. *1990 census*—1,056,660.
Chief products: *Agriculture*—sugar. *Manufacturing*—textiles.
National anthem: "Motherland."
Flag: The flag's four horizontal stripes are red, blue, yellow, and green (top to bottom). Mauritius is an island nation in the Indian Ocean. It lies east of Madagascar and southwest of India. The nation's mild climate and sandy beaches attract many tourists.

economies. Until the late 1900's, sugar was the country's chief product. Sugar production is still an important activity. About half of Mauritius is planted with sugar cane. But since the 1970's, textile production, tourism, and financial services have grown in importance.

More people are employed in textile production than in any other industry in Mauritius. Textile factories have drawn large numbers of women into the work force. Textiles are also the country's main export.

Hundreds of thousands of tourists visit Mauritius each year. Many fine hotels line the island's lovely beaches. Also, Mauritius has many banks and other financial companies that do business with foreign investors.

History. In the 1500's, Portuguese sailors became the first Europeans to visit Mauritius island. Mauritius was uninhabited until the Dutch claimed it in 1598 and named it after Prince Maurice of Nassau. The Dutch brought slaves from Madagascar to cut down the ebony forests, but they abandoned Mauritius in 1710.

In 1715, France took possession of the island and renamed it Île de France. French colonists from the neighboring island of Bourbon (now Reunion) moved to Mauritius in 1722. They imported slaves, built a port, and planted coffee, fruit, spices, sugar, and vegetables.

During the Anglo-French wars of the 1700's, the French launched attacks from the island against British shipping in the Indian Ocean and against British settlements in India. The British captured the island in 1810, made it a colony, and renamed it Mauritius.

In 1833, the United Kingdom ordered the abolition of slavery in its empire. More than 75,000 slaves were freed in Mauritius. Most of them refused to continue working on the sugar plantations. Planters then brought in nearly 450,000 Indian laborers between 1835 and 1907.

Mauritius became independent in March 1968. From 1968 to 1982, the Labor Party led by Prime Minister Sir Seewoosagur Ramgoolam controlled the government. In 1982, the leftist Mauritian Militant Movement (MMM) gained control through elections. Aneerood Jugnauth became prime minister. In 1983, he broke from the MMM and formed the Militant Socialist Movement (MSM). The party formed an alliance with other political parties and won elections held in 1983, 1987, and 1991. Jugnauth remained prime minister.

Mauritius was a constitutional monarchy from its independence in 1968 until 1992. A governor general appointed by the United Kingdom represented the British monarch. In 1992, Mauritius became a republic. An alliance of the Labor Party and the MMM won elections in 1995, and Navinchandra Ramgoolam of the Labor Party became prime minister. An alliance of the MSM and the MMM won elections in 2000, and Jugnauth, the MSM leader, became prime minister again. Larry W. Bowman

Maurois, *mawr WAH,* **André,** *ahn DRAY* (1885-1967), was the pen name of Émile Herzog, a French novelist and biographer. Maurois tried to attain in his life and writings the spirit of the French writer Michel de Montaigne—a skeptical detachment from life, mixed with humor. These qualities appear in his best works.

Maurois's place in literature probably rests with his biographies of English and French authors. His works include the lives of Percy Shelley *(Ariel,* 1923), Benjamin Disraeli *(Disraeli: A Picture of the Victorian Age,* 1927), Lord Byron *(Don Juan,* 1930), George Sand *(Lélia,* 1952), Victor Hugo *(Olympio,* 1954), and three generations of Alexandre Dumas's family *(The Titans,* 1957).

Maurois was born in Elbeuf. During World War I (1914-1918), he served as a French liaison officer with the British Army. His first works were two humorous novels based on his war experiences, *The Silence of Colonel Bramble* (1919) and *Les Discours du Docteur O'Grady (The Return of Dr. O'Grady,* 1922). *Climats (Whatever Gods May Be,* 1928) established him as a skillful novelist with an elegant style. He also wrote popular histories of France, England, and the United States. Maurois was elected to the French Academy in 1938. His *Memoirs: 1885-1967* was published in 1970. Elaine D. Cancalon

Maury, *MAWR ee,* **Matthew Fontaine** (1806-1873), was a United States naval officer and scientist who did much to improve ocean travel. He has been called the *Pathfinder of the Seas.* Maury spent years collecting information on winds and currents. His *Wind and Current Charts* formed the basis for all pilot charts issued by the U.S. government. His *Explanations and Sailing Directions,* which accompanied the charts, enabled ship operators to save time and money on voyages. Maury's *Physical Geography of the Sea and Its Meteorology* was the first textbook of modern oceanography. In the 1850's, Maury helped lay a transatlantic telegraph cable.

Maury entered the Navy as a midshipman in 1825. He took charge of the Navy Department's Depot of Charts and Instruments in 1842. In this position, he helped develop the Naval Observatory and the Hydrographic Office. He became a commander, effective in 1855.

During the American Civil War, Maury joined the Confederate forces. He was in charge of all coast, harbor, and river defenses. The Confederacy sent him to England as a special envoy. While there, he perfected an electric mine for harbor defense. After the war, he tried unsuccessfully to set up a colony of Virginians in Mexico. Later, he went to England, where he wrote textbooks and received honors and financial aid. When President Andrew Johnson pardoned Confederate leaders in 1868, Maury returned home. He became a professor of meteorology at the Virginia Military Institute.

Maury was born near Fredericksburg, Virginia. In 1930, he was elected to the Hall of Fame for Great Americans. James C. Bradford

Mauryan Empire, *MOW ree uhn,* was the first empire to provide a single government for almost all of India. Mauryan emperors ruled from about 324 to 185 B.C. Their empire centered on Magadha, a rich kingdom in the Ganges Valley.

Chandragupta Maurya ruled from about 324 to about 298 B.C. He conquered much of what is now northern India, Bangladesh, Pakistan, and Afghanistan. His son Bindusara held the throne from about 298 to 272 B.C., and Bindusara's son Ashoka (also spelled Asoka) governed from about 272 to 232 B.C. Both expanded the empire far into South India. Ashoka eventually gave up further conquest and outlawed war. The empire broke up into smaller units after Ashoka's death.

During the Mauryan Empire, public irrigation works helped farms produce rich harvests. Craftworkers made cloth, gold, jewelry, and wood products. Many people worked in farms, forests, mines, and workshops owned by the state. Many peasants and war prisoners worked as slaves to develop new agricultural lands. A system of royal inspectors, spies, and informers made sure that officials and citizens alike obeyed the emperor's will. The Mauryan Empire traded with Greece, Malaya, Mesopotamia, and Persia.

Pataliputra, the Mauryan capital, stood at what is now Patna. It was surrounded by a wall with 570 watchtowers and 64 gates. The wooden palace of Chandragupta was in a park filled with flowering trees, fountains, and fish ponds. Ashoka built a new palace of stone and also erected many stone monuments with carved inscriptions. Michael H. Fisher

Mausoleum. See **Tomb.**

Mauve, *mohv,* is a delicate pale purple or violet dye. In 1856, W. H. Perkin, an English chemist, discovered that the oxidation of *aniline* and *potassium dichromate* produces mauve dye (see **Oxidation**). Mauve is a mixture of derivatives of phenazine. It was the first synthetic coloring to be obtained from coal tar chemicals.

Howard L. Needles

Maverick, *MAV ur ihk,* **Samuel Augustus** (1803-1870), was a prominent Texas pioneer and statesman. He helped establish the Republic of Texas. His name has become part of the American language. In 1845, Maverick took a herd of 400 cattle in payment of a debt. He did not brand his cattle. They strayed, and neighboring ranchers called them *mavericks.* This came to be the name given to all unmarked cattle.

Maverick was born in South Carolina. He graduated from Yale University and practiced law in Virginia and Alabama before going to Texas. Clifford L. Egan

Max Planck Society for the Advancement of Science is the principal organization for scientific research in Germany. The society distributes government funds for research in the natural and social sciences. It supports about 65 research institutes in a wide variety of fields and employs more than 5,000 scientists. The society also maintains libraries and training institutions. Numerous winners of Nobel Prizes have been members of the society.

The Max Planck Society, formerly called the Kaiser Wilhelm Society, was founded in 1911 by the German philosopher Adolph von Harnack. In 1948, the society changed its name to honor Max Planck, a German physicist who helped formulate the quantum theory. The society publishes a journal, *Die Naturwissenschaften (The Natural Sciences).* Robert H. March

Maxim, *MAK sihm,* **Sir Hiram Stevens** (1840-1916), was an inventor who developed an automatic weapon called the Maxim gun. This gun uses the force of recoil caused by the explosion of a cartridge to throw out the empty shell and ram home a new one. Its invention changed many warfare methods.

Maxim was born near Sangerville, Maine. He worked for a time in a machine shop and in a shipbuilding yard. He did early inventive work on gas-generating plants and electric lighting. He lost his rights to an important patent in a lawsuit with Thomas Edison. Maxim then moved to England, where he set up the Maxim Gun Company. The company later merged with the Vickers munitions company.

Maxim experimented with internal-combustion engines for automobiles and airplanes. In 1894, he tested a steam-powered airplane that actually lifted itself off the ground. Maxim became a British citizen in 1900 and was knighted in 1901. See **Airplane** (Powered flight); **Machine gun.** Merritt Roe Smith

Maxim, Hudson (1853-1927), was an American inventor and explosives expert. He invented *maximite,* an explosive one and a half times as powerful as dynamite. Maxim also developed a smokeless powder and other types of explosives; a self-propelled torpedo; and a torpedo ram.

Maxim was born in Orneville, Maine, and worked first as a book publisher. He later became interested in explosives and worked briefly in the gun factory of his

brother Sir Hiram Maxim. In 1893, Hudson Maxim established the Maxim Powder Company to manufacture explosives. Four years later, he sold the plant and his patents to E. I. du Pont de Nemours & Company. Maxim served as an adviser to the Du Pont Company from 1897 until his death. Merritt Roe Smith

Maximilian, *MAK suh MIHL yuhn* (1832-1867), ruled as emperor of Mexico from 1864 to 1867. His reign was part of French Emperor Napoleon III's attempt to gain possessions and influence in North America.

The French had landed in Mexico in 1862 to collect debts. They advanced inland and captured Mexico City. Napoleon III wanted to control Mexico, and so he offered the crown to Maximilian, who was then Archduke of Austria. Maximilian accepted on the basis of "proof" given by Napoleon and by Mexican exiles in France that the Mexican people wanted him. He became emperor of Mexico in 1864. Maximilian's government adopted policies and laws that increased investments, European immigration, and the protection of private property. These measures helped lead to the modernization of Mexico.

Benito Juárez, president of Mexico, resisted the French (see **Juárez, Benito Pablo**). In 1865, Maximilian ordered that Juárez' supporters be shot on sight. His advisers assured him that resistance had ended, and that this order would prevent further trouble.

Maximilian's empire was doomed when the American Civil War ended in 1865. The United States could now enforce the Monroe Doctrine, which forbade European intervention in the Americas. Napoleon III was forced to withdraw his troops from Mexico in 1866 and 1867, leaving Maximilian without support. Maximilian's wife Carlota went to Europe to seek aid from Napoleon III and from Pope Pius IX, but failed.

Maximilian left Mexico City in 1867 to fight Juárez. He and his soldiers marched to Querétaro, where General Gómez, a trusted aide, betrayed him. He was captured by troops of the Mexican Republic, and was executed by a firing squad on June 19, 1867.

Maximilian was born in Vienna. His full name was Ferdinand Maximilian Joseph. He was a brother of Austrian Emperor Francis Joseph. He trained with the Austrian navy and served briefly as its commander in chief. He married Carlota, daughter of King Leopold I of Belgium, in 1857. W. Dirk Raat

See also **Mexico** (The French invasion).

Maximilian I, *MAK suh MIHL yuhn* (1459-1519), reigned as Holy Roman Emperor from 1493 to 1519. He extended the power of the House of Habsburg through wars and marriages (see **Habsburg, House of**).

Maximilian, son of Emperor Frederick III, married Mary, daughter of Charles the Bold of Burgundy, in 1477. He fought Mary's war with Louis XI of France for possession of Burgundy and the Netherlands. He won the war, but the Netherland states, hostile to him, signed a treaty with Louis XI in 1482. The treaty forced Maximilian to give Burgundy back to Louis XI. Mary died the same year.

Maximilian became emperor in 1493. He married Bianca, daughter of the *regent* (temporary ruler) of Milan, in 1494. He fought another long war with France for control of possessions in Italy, and lost. Maximilian was forced to grant Switzerland its independence after a war in 1499.

Maximilian arranged the marriage of his son, Philip, Archduke of Austria, to Juana of Castile, daughter of Ferdinand and Isabella of Spain, in 1496. The marriage gave Spain to the Habsburgs when Philip and Juana's son became king of Spain and, later, emperor as Charles V. Maximilian established claims on Hungary and Bohemia when his grandchildren married heirs of these countries. Maximilian was also an important patron of the arts. He was born in Wiener Neustadt, Austria.

Maxwell. See Weber.

Maxwell, James Clerk (1831-1879), a Scottish scientist, was one of the greatest mathematicians and physicists of the 1800's. He is best known for his research on electricity and magnetism and for his *kinetic theory of gases.* This theory explains the properties of a gas in terms of the behavior of its molecules. Maxwell also investigated color vision, elasticity, optics, Saturn's rings, and *thermodynamics,* a branch of physics that deals with heat and work.

Maxwell based his work on electricity and magnetism on the discoveries of the English physicist Michael Faraday. In 1864, Maxwell combined his ideas with those of Faraday and certain other scientists and formed a mathematical theory that describes the relationship between electric and magnetic fields. Both these fields exert forces on electrically charged objects. Maxwell showed that waves in combined electric and magnetic fields, called *electromagnetic waves,* travel at the speed of light. In fact, Maxwell argued that light itself consists of electromagnetic waves. In the late 1880's, the German physicist Heinrich R. Hertz conducted experiments that confirmed Maxwell's theory. See **Electromagnetic waves; Faraday, Michael; Hertz, Heinrich R.**

In his research on the kinetic theory of gases, Maxwell developed a statistical law that gives the distribution of velocities among molecules of a gas. He was the first scientist to use such a law to show how molecular behavior determines pressure, temperature, and other properties of a gas.

Maxwell was born in Edinburgh, Scotland, and studied at the University of Edinburgh. He graduated from Cambridge University in 1854 and taught there until 1856. He then became a professor of physics at Marischal College in Aberdeen, Scotland.

From 1860 to 1865, Maxwell taught physics at King's College in London. In 1865, he retired to his family estate and devoted his time to scientific writing. In 1871, Maxwell became the first professor of experimental physics at Cambridge and director of the newly established Cavendish Laboratory there.

Maxwell edited many research papers by the English physicist Henry Cavendish. These papers described Cavendish's discoveries about electricity. Maxwell's most famous work was *Treatise on Electricity and Magnetism* (1873). The key ideas of this work are often considered the basis of such developments in modern physics as the theory of relativity and the quantum theory.

May is the fifth month of the year, according to the Gregorian calendar, which is used in most of the world today. It was the third month of the early Roman calendar until the the ancient Romans moved the beginning of the year to January 1. May has always had 31 days. There are various stories about how May got its name. The most widely accepted explanation is that it was named for Maia, the Roman goddess of spring and growth. In ancient Rome, May 1 fell at a time that was sacred to Flora, the flower goddess. The Romans celebrated the day with flower-decorated parades. Today, May Day (May 1) is a spring festival in many countries. Other nations celebrate Labor Day on May 1.

Some countries celebrate Mother's Day in May. The second Sunday of the month is Mother's Day in the United States. This holiday falls on the last Sunday of May in Sweden. Flores de Mayo (Flowers of May) festivals take place throughout the Philippines during this month. These festivals honor local saints in addition to the Virgin Mary, the mother of Jesus.

Several cultures remember their dead in May. Dodenherdenking, a day to remember those killed in World War II (1939-1945), falls on May 4 in the Netherlands. Yom HaShoah, which often falls in May, honors Jews who died in the Holocaust. The last Monday of the month is Memorial Day, also called Decoration Day, in the United States. It honors those who have died in wars.

Various agricultural festivals take place in May. Residents of Sabah, a region of Malaysia, hold the Kadazan Harvest Festival throughout the month. It includes religious ceremonies, feasting, dancing, and games, the climax of which is a two-day celebration on May 30-31. Thailand's annual Royal Plowing Ceremony marks the start of the new agricultural season. The royal astronomer sets the date of this festival, which usually occurs in May. The Jewish festival of Shavuot also usually falls in this month. Shavuot began as an ancient Hebrew celebration of the wheat harvest. Today, Shavuot recalls Moses's receiving the Ten Commandments from God.

Some countries celebrate political holidays in May. Mexicans celebrate Cinco de Mayo on May 5. This date is the anniversary of the Mexican victory over the French at Puebla, Mexico, in 1862. Canadians celebrate Victoria

Important May events

1 May Day (International Labor Day).
— The Act of Union joined England and Wales with Scotland to form the United Kingdom of Great Britain, 1707.
— Empire State Building opened in New York, 1931.
2 Hudson's Bay Company chartered, 1670.
— Catherine the Great of Russia born in 1729.
3 Niccolò Machiavelli, Italian statesman and author of *The Prince,* born 1469.
— Golda Meir, former prime minister of Israel, born 1898.
4 Thomas Huxley, English biologist, born 1825.
— Haymarket Riot took place in Chicago, 1886.
5 Cinco de Mayo, Mexico.
— Kodomo-no-hi (Children's Day), Japan.
— Karl Marx, German author of *Das Kapital,* born 1818.
— Napoleon died on St. Helena, 1821.
— Memorial Day first observed in the United States, 1866.
6 First postage stamp issued in England, 1840.
— Robert E. Peary, American Arctic explorer, born 1856.
— Sigmund Freud, founder of psychoanalysis, born 1856.
— Airship *Hindenburg* blew up and burned, 1937.
7 Robert Browning, English poet, born 1812.
— Johannes Brahms, German composer, born 1833.
— Peter Ilich Tchaikovsky, Russian composer, born 1840.
— A German submarine sank the passenger liner *Lusitania* in World War I, 1915.
8 Harry S. Truman, 33rd U.S. president, born 1884.
— Victory in Europe Day (V-E Day); the day after Germany surrendered, ending World War II in Europe, 1945.
9 John Brown, American abolitionist, born 1800.
— J. M. Barrie, Scottish author, born 1860.
— Mother's Day (second Sunday in May) became a public holiday in the United States, 1914.
10 Second Continental Congress met in Philadelphia, 1775.
— First U.S. transcontinental railway completed, 1869.
— Franco-Prussian War ended, 1871.
11 Minnesota became the 27th U.S. state, 1858.
— Irving Berlin, American songwriter, born 1888.
12 King Gustavus I of Sweden born in 1496.
— Edward Lear, English author and artist, born 1812.
— Florence Nightingale, English nurse, born 1820.
— Roald Amundsen, Norwegian explorer, flew over the North Pole, 1926.
13 Empress Maria Theresa of Austria born 1717.
— Sir Arthur Sullivan, English composer, born 1842.
— United States declared war on Mexico, 1846.
14 Paraguay won independence from Spain in 1811.
— Gabriel Fahrenheit, German physicist, born 1686.
— Robert Owen, social reformer, born 1771.
— Edward Jenner, a British physician, performed the first vaccination against smallpox in 1796.
— Lewis and Clark began trip up Missouri River, 1804.
— Israel became an independent country, 1948.
15 Pista Ng Anihan (harvest festival), Philippines.
— Pierre Curie, codiscoverer of radium, born 1859.
— Flying Doctor Service (now the Royal Flying Doctor Service) began in Australia, 1928.

May birthstone—emerald

May flower—lily of the valley

May 6—airship *Hindenburg* exploded

May 7—ocean liner *Lusitania* sunk

Day, formerly known as Empire Day, on the first Monday before May 25. It honors the birthdays of both Queen Victoria (May 24, 1819) and the reigning Queen Elizabeth II (April 21, 1926) of the United Kingdom. May 25 is African Freedom Day. It is a time to focus on the independence of all African nations. Tuan Yang Chieh, China's Dragon Boat Festival, falls sometime during May. This festival honors Chu'ü Yüan, a Chinese poet and statesman of the Chou Dynasty, who drowned himself to protest corruption in the prince's court.

Each year in Japan, one week in May is set aside as Bird Week. It features such activities as bird watching, bird exhibitions, and lectures. Many Japanese trees were cut down and used as fuel during World War II. Bird nests were destroyed, and many birds died as a result. This special week encourages people to value and protect birds in their country.

May is Asian Pacific American Heritage Month in the United States. It is a time to recognize the contributions of Asian and Pacific cultures.

The hawthorn and the lily of the valley are May's flowers. May's birthstone is the emerald. Carole S. Angell

Quotations

Here's to the day when it is May
And care as light as a feather,
When your little shoes and my big boots
Go tramping over the heather.
Bliss Carman

When May, with cowslip-braided locks,
Walks through the land in green attire.
Bayard Taylor

Then came fair May, the fairest maid on ground,
Deck'd all with dainties of the season's pride,
And throwing flowers out of her lap around.
Edmund Spenser

The maple puts her corals on in May.
James Russell Lowell

May Day (May 1) is celebrated as a spring festival in many countries. It marks the revival of life in early spring after winter. May Day celebrations may go back to the spring festivals of ancient Egypt and India.

The English and other peoples whom the Romans conquered developed their May Day festivals from the Roman festival called Floralia. In the April festival of Floralia, the Romans gathered flowers to honor the goddess of springtime, Flora. Eventually, Floralia was combined with a Celtic celebration called Beltane, which was held on May 1. The Celts believed that on Beltane, the fairies were especially active.

In medieval times, May Day became the favorite holiday of many English villages. People gathered flowers to decorate their homes and churches. They sang spring carols and received gifts in return. They chose a king and queen of May. Villagers danced around a Maypole, holding the ends of ribbons that streamed from its top. They wove the ribbons around the pole until it was covered with bright colors. Dew collected on May Day morning was said to restore youth.

Other European countries had their own May Day customs. In some, the day became a time for courting. In Italy, for example, boys serenaded their sweethearts. In Switzerland, a May pine tree was placed under a girl's window. In France, May Day had religious importance. The French considered the month of May sacred to the Virgin Mary. They enshrined young girls as May queens in their churches. The May queens led processions in honor of the Virgin Mary.

The Puritans disapproved of May Day, and the day has never been celebrated with the same enthusiasm in the United States as in Britain. But in many American towns and cities, children celebrate the day with dancing and singing. They often gather flowers in handmade paper baskets and hang them on the doorknobs of the homes of friends and neighbors on May Day morning. At May Day parties, children select May queens, dance around the Maypole, and sing May Day songs. May is also celebrated in the Roman Catholic Church by electing May queens who wear flowers and lead parades called *May processions.* Such customs are probably pre-Christian in origin.

In 1889, a congress of world Socialist parties held in Paris voted to support the United States labor movement's demands for an eight-hour day. It chose May 1, 1890, as a day of demonstrations in favor of the eight-hour day. Afterward, May 1 became a holiday called Labor Day in many nations. It resembles the September holiday in the United States (see **Labor Day**). Government and labor organizations sponsor parades, speeches, and other celebrations to honor working people. The holiday has had special importance in socialist and Communist countries. Jack Santino

Maya, *MAH yuh,* were an American Indian people who developed a magnificent civilization in Central America and south Mexico. The Maya civilization reached its period of greatest development about A.D. 250 and continued to flourish for hundreds of years. The Maya produced remarkable architecture, painting, pottery, and sculpture. They made great advancements in astronomy and mathematics and developed an accurate yearly calendar. They were one of the first peoples in the Western Hemisphere to develop an advanced form of writing.

The Maya lived in an area of about 120,000 square miles (311,000 square kilometers). Today, their territory is divided among Mexico and several Central American countries. It consists of the Mexican states of Campeche, Yucatán, and Quintana Roo and part of the states of Tabasco and Chiapas. It also includes Belize, most of Guatemala, and parts of El Salvador and of Honduras.

The Maya civilization was at its peak from about A.D. 250 to 900. During that time, known as the Classic Period, it was centered in the tropical rain forest of the lowlands of what is now northern Guatemala. Many of the major Maya cities, such as Piedras Negras, Tikal, and Uaxactún, developed in this area. By about 900, most of the Maya abandoned the Guatemalan lowlands and moved to areas to the north and south, including Yucatán and the highlands of southern Guatemala. In those areas, they continued to prosper until Spain conquered almost all of the Maya in the mid-1500's.

Today, descendants of the Maya live in Mexico and Central America. They speak Maya languages and carry on some religious customs of their ancestors.

Way of life

Religion. The Maya worshiped many gods and goddesses. One Maya manuscript mentions more than 160 of them. For example, the Maya worshiped a corn god, a rain god known as *Chac,* a sun god called *Kinich Ahau,* and a moon goddess called *Ix Chel.* Each god or goddess influenced some part of Maya life. Ix Chel, for instance, was the goddess of medicine and weaving.

Religion played a central part in the daily life of the Maya. Each day had special religious importance, and

The land of the Maya included parts of present-day Mexico, Guatemala, Honduras, and El Salvador, and all of Belize. This map shows the area inhabited by three chief Maya groups and the location of major Maya cities.

WORLD BOOK maps

A Maya city called Tikal lies in what is now Guatemala. This illustration is an artist's idea of how the city may have looked about A.D. 750. In the foreground, a priest prepares for a ceremony. In the background, other priests climb the stairway to the temple, 150 feet (45 meters) high.

WORLD BOOK illustration by Alton S. Tobey

religious festivals in honor of particular gods took place throughout the year. The Maya regarded their gods as both helpful and harmful. To obtain the help of the gods, the Maya fasted, prayed, offered sacrifices, and held many religious ceremonies. Deer, dogs, and turkeys were sacrificed to feed the gods. The Maya frequently offered their own blood, which they spattered on pieces of bark paper. They practiced some human sacrifice, such as throwing victims into deep wells or killing them at the funerals of great leaders.

In their cities, the Maya built tall pyramids of limestone with small temples on top. Priests climbed the stairs of the pyramids and performed ceremonies in the temples. Major religious festivals, such as those for the Maya New Year and for each of the Maya months, took place in the cities.

The Maya observed special ceremonies when burying their dead. Corpses were painted red and then were wrapped in straw mats with a few of their personal belongings. They were buried under the floor of the houses where they had lived. Maya rulers and other important persons were buried in their finest garments within the pyramids, under the temples. Servants were killed and buried with them, along with jewelry and utensils, for use in the next world.

Family and social life. Entire Maya families, including parents, children, and grandparents, lived together. Everyone in a household helped with the work. The men and the older boys did most of the farmwork, such as clearing and weeding the fields and planting the crops. They also did most of the hunting and fishing. The women and the older girls made the family's clothes, prepared meals, raised the younger children, and supplied the house with firewood and water. The Maya had no schools. The children learned various skills by observing adults and helping them.

Religious festivals provided one of the favorite forms of recreation for the Maya. These festivals were held on special days throughout the year. Dancing and feasts took place at the festivals. In addition, the Maya had a sacred game that was played on special courts. The players tried to hit a rubber ball through a stone ring with their hips.

Food, clothing, and shelter. Maya farmers raised chiefly beans, corn, and squash. Corn was the principal food of the Maya, and the women prepared it in a variety of ways. They made flat corn cakes, which today are called *tortillas,* as a type of bread. The Maya also used corn to make an alcoholic drink called *balche,* which they sweetened with honey and spiced with bark. The Maya also raised avocados, chili peppers, and sweet potatoes.

Farmers became skilled at making the best use of natural resources. They dug canals in swampy lowlands to drain the soil and used the unearthed soil to build raised fields in which they grew crops. On sloping land, farmers built terraces to hold the soil in place and walls to control water flow. With such methods, the Maya grew enough food to feed a large population.

Dogs were the only tame animals of the Maya, but the people raised turkeys and honey bees on their farms. The Maya hunted deer, rabbits, piglike animals called *peccaries,* and other wild animals. They fished and collected shellfish from the rivers and sea. They also gathered fruits and vegetables from the countryside.

The clothing of the Maya kept them comfortable in the hot, tropical climate. Men wore a *loincloth,* a strip of cloth tied around their hips and passed between their legs. Women wore loose dresses that reached their ankles. The people wove these garments from cotton or other fibers. The people of the upper classes wore finer clothes decorated with embroidery and ornaments. They had splendid headdresses made of the brightly colored feathers of tropical birds. The wealthy also wore large amounts of jewelry, much of which was carved out of green jade and colorful shells.

Maya farmers lived in rural homesteads or small villages near their fields. They built their houses from

poles lashed together and used palm leaves or grass to thatch the roofs. Many Maya cities were home to tens of thousands of people. One of the largest known cities of the Classic Period, Tikal, probably had a population of about 60,000 at its peak. Another 30,000 people lived in the surrounding area. People from the countryside gathered in the Maya cities for markets, religious festivals, and other important events.

Trade and transportation. The Maya took part in a trade network that linked a number of groups in Central America. The people of the Maya lowlands exported many items, including handicrafts, forest and sea products, and jaguar pelts. They imported jade, volcanic glass, and the feathers of a bird called the *quetzal* from the highlands of Guatemala, where other Maya lived.

The Maya of Yucatán sent salt and finely decorated cottons to Honduras. In return, they received cacao beans, which they used in making chocolate. The Maya also transported goods as far as the Valley of Oaxaca in Mexico and the city of Teotihuacán, near what is now Mexico City. They carried most goods on their backs or on rivers in dugout canoes. They did not use the wheel or any beasts of burden, such as horses or oxen.

Government. Each Maya city governed its surrounding area, and some large cities each controlled one or more smaller cities. A city ruler would usually be succeeded by his younger brother or by his son. In some cases, generations of a single family ruled for hundreds of years. For example, a series of at least 29 kings from one family ruled Tikal from before A.D. 300 until sometime after 869. The Maya never united to form a central governmental unit. But in late Maya times, the governments of such cities as Chichén Itzá and Mayapán controlled large parts of the Maya population.

Communication and learning. The Maya developed an advanced form of writing that consisted of many symbols. These symbols represented combinations of sounds or entire ideas and formed a kind of *hieroglyphic* writing (see **Hieroglyphics**).

The Maya kept records on large stone monuments called *stelae,* as well as on some buildings and household utensils. They used the stelae to record important dates and to take note of great events in the lives of their rulers and the rulers' families. The Maya also made books of paper made from fig tree bark. Several books from the 1100's to the early 1500's have survived. They contain astronomical tables, information about religious ceremonies, and calendars that show lucky days for such activities as farming and hunting.

Other cultural advances by the Maya included the development of mathematics and astronomy. The Maya used a mathematical system based on the number 20, instead of 10 as in the decimal system. A dot represented the number one, a bar represented five, and special symbols represented zero. The Maya were among the first people to use symbols for the idea of zero. Maya priests observed the positions of the sun, moon, and stars. They made tables predicting eclipses and the orbit of the planet Venus.

The priests also used mathematics and astronomy to develop two kinds of calendars. One was a sacred almanac of 260 days. Each day was named with one of 20 day names and a number from 1 to 13. Each of the 20 day names had a god or goddess associated with it. The priests predicted good or bad luck by studying the combinations of gods or goddesses and numbers. The Maya also had a calendar of 365 days, based on the orbit of the earth around the sun. These days were divided into 18 months of 20 days each, plus 5 days at the end of the year. The Maya considered these last 5 days of the year to be extremely unlucky. During that period they fasted, made many sacrifices, and avoided unnecessary work.

Clay sculpture (A.D. 700 to 900), 5 in. (12.5 cm) high; Museo Nacional de Antropologia e Historia, Mexico City (Bradley Smith)

A Maya ballplayer wore thigh guards and a thick protective belt to compete in a sacred ball game. The players hit a rubber ball through a stone ring with their hips.

Clay sculpture, 16 in. (40 cm) high; Museo Nacional de Antropologia e Historia, Mexico City (Lee Boltin)

A sculpture of the Maya corn god has ears of corn in its headdress. Corn was the chief food of the Maya. They prayed to this god for plentiful harvests and offered sacrifices to him.

The Maya used herbs and magic to treat illness. Scholars know little else about Maya medicine.

Arts and crafts. The Maya produced exceptional architecture, painting, pottery, and sculpture. Highly skilled architects built tall pyramids of limestone, with small temples on top. The Maya also built large, low buildings where rulers and other nobles lived. Many buildings had flat ornaments called *roof combs,* which extended from the high point of the roof. The combs gave buildings the appearance of great height.

Maya artists decorated walls with brightly colored murals that featured lifelike figures taking part in battles and festivals. The artists outlined the figures and then filled in the color. They rarely shaded the colors. A similar type of painting appears on Maya pottery.

The Maya made small sculptures of clay and carved huge ones from stone. Most of the small sculptures were figures of men and women. The large sculptures, some standing over 30 feet (9 meters) high, were carved with portraits of rulers.

History

The Preclassic Period. The heart of the Maya civilization centered around what is now the *department* (state) of El Petén in the lowlands of northern Guatemala. The first farmers may have settled there as early as 1000 B.C. They came from areas surrounding El Petén—mostly from highlands to the west and south—in search of fertile land. The new settlers lived in small villages. They gathered food from the surrounding forest and raised crops.

By 800 B.C., the Maya lowlands were completely settled. At that time, the Olmec lived west of the Maya. The Olmec were probably the Central American inventors of numbers and writing. They also had well-developed art. The Olmec civilization influenced Maya culture. The Maya, like the Olmec, began to build pyramids and carve stone monuments. See **Olmec Indians**.

Stone sculpture (A.D. 784) by an unknown Maya artist; Lee Boltin

A Maya monument called a *stele* stands in Copán, a city in what is now Honduras. The Maya used such sculptures to record important dates and to note events in their rulers' lives.

Codex Tro-Cortesianus (late 1400's); Museo de America, Madrid, Spain (Ampliaciones y Reproducciones MAS)

Maya writing used symbols that represented entire ideas or combinations of sounds. This section of a Maya manuscript came from an astrology book used by priests.

The Maya built their first large pyramids between 600 and 400 B.C., during the middle of the Preclassic Period. By late in the Preclassic Period, between 400 B.C. and A.D. 250, there were several large Maya settlements in the lowlands. Some of the largest Maya pyramids stood in one of these settlements, at a site now called El Mirador, in northern Guatemala.

The Classic Period of the Maya civilization lasted from about A.D. 250 to 900. During those years, the Maya founded their greatest cities and made their remarkable achievements in the arts and sciences. They also perfected the practice of erecting stelae to honor the most important events in the lives of their leaders.

During the first 300 years of the Classic Period, the city of Teotihuacán, near present-day Mexico City, had a strong influence on Maya art and architecture. Throughout the Classic Period, populations grew, and new cities were founded. Toward the end of the period, as competition for land and other resources increased, rival cities began to fight each other. Sometimes a growing city would break away from a larger city's control. In other cases, one city conquered another and captured its ruler. Defeated rulers and other important prisoners of war were sacrificed in religious ceremonies, and the conquered city probably paid something to the victor. By about 700, the Maya of the Classic Period reached their peak in population and prosperity.

Then, beginning in the 800's, the Maya stopped erecting stelae in city after city. They abandoned their major centers in the Guatemala lowlands one by one and finally left most of this lowland region. Scholars are still trying to discover the reasons for the collapse of Classic Maya society. Some experts point to a combination of such factors as overpopulation, disease, exhaustion of natural resources, crop failures, and the movement of other groups into the Maya area.

The Postclassic Period began about 900, when the Maya abandoned their cities in the Guatemalan lowlands. Some Maya moved north to build new cities in the lowlands of Yucatán. Others moved to southern Guatemala's highlands and built cities there.

Important changes took place in Maya political and economic systems during the Postclassic Period. For example, sea trade became much more common, resulting in prosperity for Maya cities near the seacoasts. Between 900 and 1200, Chichén Itzá, in Yucatán, grew to be the largest and most powerful Maya city. It was governed by a council of nobles—unlike Maya cities of the Classic Period, which each had a single ruler. Chichén Itzá dominated Yucatán by a combination of military strength and control over important trade routes. Chichén Itzá traded with, and formed other ties to, regions beyond the Maya area. These areas included Tula, the leading city of the Toltec Indians' empire in the highlands of what is now central Mexico. See **Toltec Indians.**

Chichén Itzá declined around 1200, and Mayapán replaced it as the chief Maya city. Although Mayapán never became as powerful as Chichén Itzá had been, it controlled much of Yucatán for another 200 years.

About 1440, the leaders of some Maya cities revolted against the Mayapán rulers and defeated them. Yucatán was then divided into separate warring states. About the same time, several Maya states in the highlands of southern Guatemala used military force to dominate other Maya in that region. Then, in the early 1500's, Spanish conquerors invaded the Maya territories. By the mid-1500's, they had overcome almost all the Maya.

WORLD BOOK photo by Joya Hairs

The ruins of Tikal in Guatemala are all that remain of the great Maya city. The restored Temple of the Giant Jaguar, *left,* rises 150 feet (45 meters) above the site.

The Maya heritage. Today, many people of Mexico and Central America speak one of more than 20 languages and dialects that developed from the ancient Maya language. Some of these people live in the highlands of Mexico and Guatemala. Others inhabit the northern part of the Yucatán Peninsula in Mexico. Many descendants of the Maya farm as did their ancestors and carry on some of the traditional religious customs.

The ruins of the Maya cities are tourist attractions. Sites in Mexico include the ruins of Bonampak and Palenque in Chiapas, and Chichén Itzá in northern Yucatán. Tourists also visit the ruins of Tikal in Guatemala and of Copán in Honduras. Robert J. Sharer

Mayapple is a plant that grows wild in wooded areas of the eastern United States, as far west as Texas. It is also called *mandrake, wild lemon,* and *wild jalap.* The mayapple grows in large groups. Its large leaves have 5 to 7 lobes and look like small umbrellas. They usually grow in pairs, on a stem about 1 foot (30 centimeters) high. A white flower grows on a stalk in a fork of the stem. The flower is about 2 inches (5 centimeters) wide.

The mayapple produces a small, round fruit about the size of a golf ball. Before it ripens, the fruit is green and bitter. If eaten, it can cause severe stomach pain. The ripe fruit is yellow and can be eaten. Podophyllum resin, a drug used to remove warts, comes from the *rhizomes* (underground stems) of the mayapple. Fred T. Davies, Jr.

Scientific classification. The mayapple belongs to the barberry family, Berberidaceae. It is *Podophyllum peltatum.*

Maybach, *MY bahk,* **Wilhelm,** *VIHL hehlm* (1846-1929), was a German inventor, engineer, and designer. During the early 1870's, he began working for German automotive pioneer Gottlieb Daimler (see **Daimler, Gottlieb**). In 1883, Maybach and Daimler developed an improved gasoline engine. They modified this engine and in 1885 installed it on a bicycle, thus creating the first motorcycle. In 1886, they used a slightly more powerful engine to power a carriage. Daimler founded the Daimler Motor Company in 1890. In 1895, Maybach became its technical director and played a key role in the de-

sign of the company's first Mercedes car in 1901. In 1907, he left the company to build engines for airships manufactured by German aircraft pioneer Ferdinand von Zeppelin. Maybach was born on Feb. 9, 1846, in Heilbronn. He died on Dec. 29, 1929. Joel W. Eastman

Mayer, *MY uhr,* **Julius Robert von** (1814-1878), was a German physician and physicist. He and the English physicist James Joule shared credit for discovering the law of conservation of energy (see **Joule, James**). That principle, known as the first law of thermodynamics, states that the total energy of the universe cannot be increased or lessened. Mayer completed his article on heat and energy in 1842. Joule reached the same conclusions while working independently. It has never been determined which scientist was the first to make the discovery. Mayer was born on Nov. 25, 1814, at Heilbronn. He died on March 20, 1878. Richard G. Olson

See also **Heat** (Heat and energy).

Mayer, *MY uhr,* **Maria Goeppert,** *mah REE ah GOH puhrt* (1906-1972), a German-born physicist, shared the 1963 Nobel Prize in physics with J. Hans Jensen of Germany and Eugene Paul Wigner of the United States. Mayer and Jensen, working independently, prepared almost identical papers on the shell structure of atomic nuclei. They discovered that atomic nuclei possess shells similar to the electron shells of atoms. Those shells contain varying numbers of protons and neutrons.

Maria Goeppert was born on June 28, 1906, in Kattowitz, Germany (now Katowice, Poland). She married Joseph E. Mayer, an American chemist, in 1930, and moved to the United States. In 1960, they both joined the faculty of the University of California, San Diego. Maria died on Feb. 20, 1972. Richard L. Hilt

Mayflower. See Arbutus.

Mayflower was the ship that carried the first Pilgrims to America, in 1620. It was built around 1610 and probably had three masts and two decks. It probably measured about 90 feet (27 meters) long and weighed about 180 tons (163 metric tons). Its master, Christopher Jones, was a quarter-owner.

Wide World

The *Mayflower II,* built as the original *Mayflower* is thought to have looked, made a 54-day voyage across the Atlantic Ocean in 1957. This was 11 days fewer than the Pilgrims' trip in 1620.

The *Mayflower* left England on Aug. 15, 1620 (August 5 according to the calendar then in use) with another ship, the *Speedwell.* After turning back twice because of leaks on the *Speedwell,* the *Mayflower* sailed alone from Plymouth on September 16 (September 6), with 102 passengers. The ship reached Cape Cod on November 21 (November 11). It reached the present site of Plymouth, Massachusetts, on December 26 (December 16), five days after a small party explored the site.

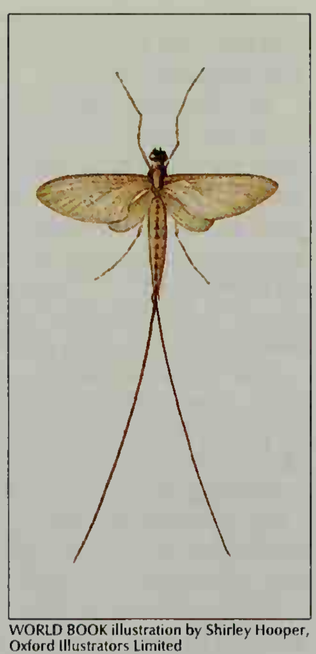
The *Mayflower* left America on April 15, 1621 (April 5, 1621). Historians are not certain what happened to the ship after it returned to England. Some believe it was dismantled after Jones died in 1622, although a ship called the *Mayflower* made trips to America after that. Others believe that William Russell bought the *Mayflower* for salvage and used its hull as a barn roof. The barn stands in Jordans, a village outside London.

The *Mayflower II,* built as the original *Mayflower* is thought to have looked, is kept in Plymouth, Massachusetts. In 1957, it crossed the Atlantic in 54 days. The Britons who built the replica gave it to the American people as a symbol of friendship. Joan R. Gundersen

See also **Pilgrims; Plymouth Colony; Plymouth Rock.**

Mayflower Compact was a written agreement for self-government signed by 41 members of the Plymouth Colony. On Nov. 21 (then Nov. 11), 1620, the ship *Mayflower* anchored off Cape Cod, Massachusetts. The Pilgrim leaders persuaded 41 men aboard to sign the *Mayflower Compact* and set up a government in Plymouth Colony. The original compact has disappeared. The version below follows the spelling and punctuation in *Of Plimoth Plantation,* written between 1630 and 1651 by William Bradford, second governor of the colony, and published in 1856 as *History of Plymouth Plantation.*

"In ye name of God Amen. We whose names are underwritten, the loyall subjects of our dread soveraigne Lord King James, by ye grace of God, of Great Britaine, Franc, & Ireland king, defender of ye faith, &c. Haveing undertaken, for ye glorie of God, and advancemente of ye Christian faith and honour of our king & countrie, a voyage to plant ye first colonie in ye Northerne parts of Virginia, doe by these presents solemnly & mutualy in ye presence of God, and one of another, covenant, & combine ourselves togeather into a Civill body politick; for our better ordering, & preservation & furtherance of ye ends aforesaid; and by vertue hereof to enacte, constitute, and frame such just & equall Lawes, ordinances, Acts, constitutions, & offices, from time to time, as shall be thought most meete & convenient for ye generall good of ye colonie: unto which we promise all due submission and obedience. In witnes whereof we have hereunder subscribed our names at Cap-Codd ye -11- of November, in ye year of ye raigne of our soveraigne Lord King James of England, France, & Ireland ye eighteenth, and of Scotland ye fiftie fourth. Ano Dom. 1620."



Joan R. Gundersen

Mayfly is a dainty insect with lacy wings and a slender, forked tail that trails behind it in flight. Mayflies are commonly called *dayflies* because of their short lives. Adult

mayflies live only a few hours or a few days. They do not eat and usually have undeveloped mouthparts. Mayflies actually are not true flies. A true fly has two wings. Mayflies have four wings. Mayflies are also known as *shad flies* or *duns*. Imitation mayflies are used as fishing lures.

Young mayflies are called *nymphs* or *naiads*. They hatch from eggs laid in streams and ponds. A nymph breathes through gills and feeds on water plants. It lives for a few months to two years in the water. It then leaves the water, sheds its skin, and becomes a winged *subimago*, or subadult. Mayflies are the only insects that go through this stage. After a few hours, the subimago sheds its skin and becomes a full-grown adult. Mayflies are most common in early spring, but may occur until late fall. The nymphs serve as food for fish.

Mayfly

Scientific classification. Mayflies make up the order Ephemeroptera. Sandra J. Glover

Mayhem, *MAY hehm,* in law, is the offense of making a person less capable of self-defense by maiming the body or by destroying or injuring one of its members. Such injuries call for legal distinctions, because not all injuries which result from assault are mayhem. Biting off a person's ear or nose was not mayhem under the old common law. But cutting off a finger or destroying an eye came under that law, because such an injury would make a person less capable of self-defense.

Modern statutes now regard as mayhem any crime of violence which causes a permanent bodily injury. The person who inflicts the injury is subject to a civil suit as well as to criminal prosecution. The word is an old form of the word *maim.* George T. Felkenes

Maynor, Dorothy (1910-1996), a black American singer, gained fame for her pure, sweet soprano voice. She was especially effective performing the music of Wolfgang Amadeus Mozart and George Frideric Handel. She also excelled in singing spirituals and German *lieder* (songs). Maynor's career was limited to concerts and recordings because major opera houses would not hire black artists while she was active.

Maynor was born in Norfolk, Virginia. Her father was a clergyman. She first sang in his church's choir. Conductor Serge Koussevitzky heard her at the Tanglewood Festival in 1939 and hired her as a soloist with the Boston Symphony Orchestra. Martin Bernheimer

Mayo, Charles Horace (1865-1939), was a prominent American surgeon. He helped his father and his older brother, William, found the Mayo Clinic in Rochester, Minnesota (see **Mayo Clinic**). Mayo and his brother pioneered the use of medical group practice at the clinic. They also started the Mayo Foundation and the Mayo Graduate School of Medicine.

Mayo was born in Rochester. He graduated from Chicago Medical College (now Northwestern University Medical School) in 1888. Mayo was best known for his skill in thyroid surgery. He was professor of surgery at the University of Minnesota Medical School from 1915 to 1936. He was president of the American Medical Association in 1917 and the American College of Surgeons in 1925. Mayo also served in the armed forces during World War I (1914-1918) and became a brigadier general in the medical reserve in 1921. Dale C. Smith

Mayo, William James (1861-1939), an American physician, helped found the Mayo Clinic in Rochester, Minnesota, along with his father and his younger brother, Charles (see **Mayo Clinic**). William and his brother pioneered the development of medical group practice at the clinic. They donated $1\frac{1}{2}$ million in 1915 to establish the Mayo Foundation and the Mayo Graduate School of Medicine. The school became one of the world's leading graduate medical centers.

Mayo graduated from the University of Michigan in 1883. He was president of the American Medical Association in 1906 and the American Surgical Association in 1914. He served in the Army Medical Reserve Officers Corps during World War I (1914-1918) and became a brigadier general in the medical reserve in 1921. Mayo was born in Le Sueur, Minnesota. Dale C. Smith

Mayo, William Worrall (1819-1911), a surgeon, made important contributions to American medicine. With his sons William and Charles, he founded the world famous Mayo Clinic in Rochester, Minnesota.

Mayo was born in Manchester, England, and studied at Owens College there. He came to the United States in 1845. He graduated from the University of Missouri in 1854. Mayo began practicing medicine in Minnesota in 1855 and soon became the leading physician and surgeon in the area. He was one of the first doctors in the West to use a microscope in diagnosis.

Mayo also took an active part in organizing the Minnesota Territory. In 1862, he served as a volunteer surgeon during an outbreak of fighting with Sioux Indians. He became provost surgeon for southern Minnesota in 1863. In 1883, after a cyclone struck Rochester, Mayo was placed in charge of an emergency hospital. Sisters of the Order of St. Francis assisted him and then built a permanent hospital in Rochester. This hospital, called St. Marys Hospital, opened in 1889, and Mayo served as its chief of staff until he was succeeded by his sons. Together, the three Mayos built up the practice that eventually became known as the Mayo Clinic. Dale C. Smith

Clapesattle, Helen. *The Doctors Mayo.* 3rd ed. Mayo Found., 1989.

Crofford, Emily. *Frontier Surgeons: A Story About the Mayo Brothers.* Carolrhoda, 1989. For younger readers.

Mayo Clinic, in Rochester, Minnesota, is one of the world's largest medical centers. Staff physicians care for clinic patients through an integrated group practice of medicine. A 12-member board of governors, which functions through several committees, administers the clinic. The clinic has nearly 900 physicians and medical scientists on its staff. About 800 younger doctors assist the staff of the Mayo Clinic as part of their residency

training in medical and surgical specialties.

William Worrall Mayo and his sons, William James and Charles Horace Mayo, began their team practice in 1889 as staff physicians for St. Marys Hospital. Their successes in surgery became widely recognized, and the number of physicians on their staff gradually increased. In 1914, the brothers built their own medical center. The Mayo Clinic now registers more than 400,000 patients a year. The clinic has cared for millions of patients since 1907. In 1986, the Mayo Clinic merged with St. Marys Hospital and Rochester Methodist Hospital, both in Rochester. Critically reviewed by the Mayo Clinic

Mayor is the head of a city government in the United States and many other countries. The people of England have used the title for hundreds of years. Colonists in America brought the name and office with them from England. In the United States, two kinds of mayors, called strong and weak, developed.

In cities that have a *strong-mayor* government, the mayor takes a leading part in city administration. Such mayors enforce laws passed by the city council and can veto council rulings. They appoint lesser officials and may name a managing director or chief administrative officer to supervise government operations. In most strong-mayor governments, the mayor is chosen by the voters in a direct election.

In cities that have a *weak-mayor* government, the mayor has little executive authority. The mayor is the head of the government of the city. But the city council has the final authority in directing the city's administration. In most weak-mayor governments, the council elects one of its members as mayor.

In Austria, Belgium, Germany, and the Netherlands, the mayor is often called the *burgomaster*. The duties of a burgomaster are substantially those of a mayor in the United States. The position of mayor in the United Kingdom is largely honorary. In Canada, the mayor enforces ordinances, supervises lower officials, and presents proposals to the city council. Susan H. Ambler

Maypole. See May Day.

Mays, Benjamin Elijah (1894-1984), was an American Baptist minister, educator, and public speaker. He was president of Morehouse College in Atlanta, Georgia, from 1940 to 1967. Mays was president of Morehouse when civil rights leader Martin Luther King, Jr., attended the college. King's admiration for Mays influenced his decision to become a minister. Mays delivered a nationally televised speech at a memorial service for King, who was shot to death in 1968.

Mays was born in Epworth, near Greenwood, South Carolina. He earned a B.A. degree at Bates College in Maine and a Ph.D. degree at the University of Chicago. He became a minister in 1922. Mays was dean of the School of Religion at Howard University from 1934 to 1940. He wrote *The Negro's God as Reflected in His Literature* (1938), and was coauthor of *The Negro's Church* (1933). His autobiography, *Born to Rebel,* was published in 1971. In 1982, Mays received the Spingarn Medal for his work in education and theology. Edgar Allan Toppin

Mays, Willie (1931-), became one of the most exciting players in baseball history. He electrified crowds with his sensational fielding, explosive hitting, and daring base running. In his major league career, he hit 660 home runs. Only Henry Aaron and Babe Ruth hit more.

UPI/Bettmann Newsphotos

Willie Mays

Mays played center field for the New York (later San Francisco) Giants during most of his major league career. He was named the National League's Most Valuable Player in 1954 and 1965. He led the league in home runs four times and in stolen bases four times. Mays won the league batting championship in 1954 and had a career batting average of .302. During the 1954 World Series, Mays made a spectacular running, over-the-shoulder catch of a long fly hit by Vic Wertz of the Cleveland Indians. The catch ranks among the most memorable plays in series history.

Willie Howard Mays was born in Westfield, Alabama, a town near Fairfield. He joined the Giants in 1951. In 1972, he was traded to the New York Mets. He retired as a baseball player in 1973. Mays was elected to the National Baseball Hall of Fame in 1979. Dave Nightingale

Mazarin, *MAZ uh rihn* or *ma za RAN,* **Jules Cardinal** (1602-1661), was, in effect, the ruler of France from 1643 until his death. He succeeded Cardinal Richelieu as chief minister to King Louis XIII in 1642. Louis died the following year. Mazarin then became the chief adviser of Anne of Austria, who ruled as *regent* (temporary ruler) for her 4-year-old son, Louis XIV. Anne and Mazarin brought the Thirty Years' War to an end in 1648 and, in 1659, won a war between France and Spain. Their rule strengthened the monarchy, brought peace at home and abroad, and made France supreme in Europe.

In foreign and domestic policy, Mazarin mainly preserved the work of Louis XIII and Richelieu. However, many French people resented him for the continuation of the Thirty Years' War and its tax burdens. Anne, who was Spanish-born, and Mazarin, who came from Italy, were both criticized for their foreign birth. They overcame a rebellion known as the *Fronde* (1648-1653). Anne and Mazarin preferred to resolve disputes by using money and diplomacy rather than the harsh methods employed by Louis XIII and Richelieu. Mazarin used his position to enrich himself and his family, as did most royal servants in his day.

Mazarin was born Giulio Mazarini in the Italian region of Abruzzi. He was a captain in the pope's army early in the Thirty Years' War and then entered the papal diplomatic service. He and Richelieu won each other's respect while Mazarin was on a mission to France in 1630. Mazarin was granted French citizenship in 1639. He became a cardinal in 1641, though he was never ordained as a priest. Donald A. Bailey

Maze. See **Labyrinth**.

Mazzei, *maht TSA ee,* **Philip** (1730-1816), was an Italian physician and merchant who supported the American Colonies during the Revolutionary War in America (1775-1783). He was a friend of Thomas Jefferson, who

became the third president of the United States.

Mazzei was born in Poggio-a-Caiano, Italy, near Florence. He was trained as a surgeon and practiced medicine in Turkey until 1755, when he moved to London and became a wine merchant. In 1773, Mazzei went to America. He conducted agricultural experiments and established a wine, olive oil, and silk company in Virginia. Jefferson was a partner in the firm, and Mazzei lived near Monticello, Jefferson's estate.

Mazzei wrote many articles that demanded independence for the American Colonies. Jefferson translated these articles from Italian into English. In 1779, Mazzei went to Italy, where he collected political and military information for Virginia's leaders. He returned to Virginia after the war but moved to France in 1785. In 1791, Mazzei went to Poland, where he served as an adviser to the king. He returned to Italy in 1792 and spent the rest of his life there. William Morgan Fowler, Jr.

Mazzini, *maht TSEE nee,* **Giuseppe,** *joo ZEHP peh* (1805-1872), was an Italian patriot who played an important part in uniting Italy in 1861. He favored revolts that would free Italy from Austrian rule and unite it as a republic.

Mazzini began his political career in 1827 by joining the *Carbonari,* a secret organization that wanted to unify Italy. A bold leader, he was exiled from Italy in 1831. Except for brief return visits, Mazzini spent the rest of his life in exile in England, France, and Switzerland. But he kept in contact with liberal *republicans* (opponents of monarchy) in Italy. In 1832, Mazzini founded *Young Italy,* a group that organized uprisings against Austria's rule of Italy. Although the uprisings failed, Young Italy convinced many Italians to support unification.

In 1848, revolutions broke out in all the major Italian cities. The following year, Mazzini returned to Italy and became one of the leaders of a new republic in Rome. But French troops attacked the new government and captured Rome, forcing Mazzini into exile again.

Italy finally was united in 1861, under King Victor Emmanuel II of Sardinia. But Mazzini wanted Italy to be a republic, not a monarchy. He organized republican revolts, but they all failed. Italy did not become a republic until 1946. Mazzini was born in Genoa. Susan A. Ashley

Mbabane, *EHM buh BAHN* (pop. 38,636), is the administrative capital of Swaziland, a country in southern Africa. Mbabane lies in a mountainous region of Swaziland 200 miles (320 kilometers) east of Johannesburg, South Africa (see **Swaziland** [map]). Mbabane was founded as a mining camp. Tin mining and farming are major occupations. Most people living there are Swazi. The Swazi are Bantu-speaking people who have much in common with the Zulus of South Africa. Bruce Fetter

Mbeki, *uhm BEHK ee,* **Thabo,** *TA boh* (1942-), became president of South Africa in 1999. He succeeded Nelson Mandela, who retired. Mbeki had been an activist in the African National Congress (ANC), a largely black group that opposed the minority white population's rule of South Africa. The ANC led a movement that led to the country's first elections open to all races and first multiracial government in 1994. That same year, Mbeki became deputy president of the nation.

Mbeki, whose full name is Thabo Mvuyelwa Mbeki, was born in Idutywa in the Transkei region of South Africa. His parents were political activists.

AP/Wide World
Thabo Mbeki

From 1962 to 1990, Mbeki lived in exile. He completed a master's degree in economics at the University of Sussex in the United Kingdom in 1966. While living outside South Africa, Mbeki continued to work for the ANC and gain publicity for its cause.

Mark W. DeLancey

Mc. See Mac.

McAdam, John Loudon (1756-1836), a Scottish engineer, originated the *macadam* road surface. He was the first person to recognize that normal soil, if well-prepared, drained, and protected, can support the weight of traffic without an expensive foundation made of rock. His macadam pavements consisted of small stones packed into layers over dry, prepared soil. The stones provided a smooth surface and kept the soil dry. McAdam was born in Ayr, Scotland. Terry S. Reynolds

McAfee, Mildred Helen (1900-1994), an American educator, commanded the WAVES during World War II. She received the Distinguished Service Medal in 1945 for her work as the first director of the WAVES, the women's reserve of the United States Navy. She was president of Wellesley College from 1936 to 1949.

McAfee was born in Parkville, Missouri. She graduated from Vassar College and received a master's degree from the University of Chicago. In 1945, she married Douglas Horton, a clergyman. She was the first woman chosen to the board of directors of Radio Corporation of America (RCA). Miriam Schneir

McAuliffe, *muh KAW lihf,* **Christa** (1948-1986), was chosen to become the first schoolteacher to travel in space. The National Aeronautics and Space Administration (NASA) selected McAuliffe from over 11,000 teachers who had applied for the post. She planned to document her flight in three parts—a diary beginning at the time of her selection, a journal of the actual flight, and her thoughts following the flight. On Jan. 28, 1986, the space shuttle *Challenger,* which carried McAuliffe, was destroyed in an accident shortly after take-off. The accident killed McAuliffe and the six other crew members.

Sharon Christa Corrigan was born in Boston. She married Steven McAuliffe in 1970. They had two children. McAuliffe earned a bachelor's degree from Framingham State College in 1970. She received a master's degree in education from Bowie State College in 1978. From 1982 until her death, McAuliffe taught social studies at Concord High School in Concord, New Hampshire.

Lillian D. Kozloski

McBain, Ed (1926-), is the pen name of Evan Hunter, a leading American writer of detective fiction. He is best known for his 87th Precinct series of novels set in a large American city. Each novel features members of the precinct police squad as the heroes. The series began with *Cop Hater* (1956) and is noted for its realism, sense of humor, and rich variety. Another series of mystery

novels features a Florida lawyer named Matthew Hope. The series began with *Goldilocks* (1978).

McBain was born in New York City. His given and family name was Salvatore Lombino. In 1952, he legally changed it to Evan Hunter. Among his best-known works under this name are the novels *The Blackboard Jungle* (1954) and *Last Summer* (1968). As Hunter, he also wrote the screenplay for the Alfred Hitchcock film *The Birds* (1963). His other pen names include Curt Cannon, Hunt Collins, and Richard Marsten. David Geherin

McCain, John Sidney, III (1936-), a Republican from Arizona, has been a member of the United States Senate since 1987. He has chaired the committees on Indian Affairs and on Commerce, Science, and Transportation, and has served on the Armed Services Committee. In 1999, McCain began campaigning for the Republican presidential nomination for the 2000 election. But he withdrew from the race in early 2000.

In the mid-1990's, McCain worked with Daniel K. Inouye, a Democrat from Hawaii, on a bill to regulate casino gambling on Indian reservations. McCain and Russell Feingold, a Democrat from Wisconsin, cosponsored a bill to encourage limits on campaign spending. Congress approved a version of the bill in 2002.

McCain was born on Aug. 29, 1936, in the Panama Canal Zone, where his father was serving in the U.S. Navy. Both his grandfather and his father were Navy admirals. In 1958, McCain graduated from the U.S. Naval Academy. He then entered the Navy and served as a fighter pilot. In 1967, during the Vietnam War, his plane was shot down in Vietnam, and he was held prisoner there until 1973. In 1973 and 1974, McCain attended the National War College. From 1977 to 1980, he served as director of the Navy Senate Liaison Office. He retired from the Navy in 1981.

McCain was elected to the U.S. House of Representatives in 1982 and in 1984. In 1986, he won election to his first term in the U.S. Senate. His autobiography, *Faith of My Fathers,* was published in 1999. Jackie Koszczuk

McCarthy, Eugene Joseph (1916-), served as a United States senator from Minnesota from 1959 to 1971. He was a leading candidate for the 1968 Democratic presidential nomination. As a candidate, he consolidated the widespread opposition to the Vietnam War. He attracted much student support, and won primary elections in Wisconsin and Oregon. He was narrowly defeated by President Lyndon B. Johnson in the opening primary in New Hampshire.

McCarthy's success in New Hampshire influenced Senator Robert F. Kennedy of New York to enter the Democratic race. It also helped persuade Johnson not to run for reelection. McCarthy lost in three states to Kennedy. Vice President Hubert H. Humphrey won the Democratic nomination. McCarthy was also an unsuccessful candidate for the 1972 and 1992 Democratic presidential nominations. In 1976 and 1988, he ran for the presidency as an independent candidate but received less than 1 percent of the popular vote in each election.

McCarthy was born on March 29, 1916, in Watkins, Minnesota. He earned degrees from St. John's University and the University of Minnesota, and taught high school and college for 10 years. McCarthy was a member of the House of Representatives from 1949 to 1959.

Charles Bartlett

McCarthy, Joseph Raymond (1908-1957), a Republican United States senator from Wisconsin, was one of the most controversial figures in American politics. He gained attention in the early 1950's by charging that Communists had infiltrated the government. He conducted several public investigations of Communist influence on U.S. foreign policy. Some people praised him as a patriot, but others condemned him for publicly accusing people of disloyalty without sufficient evidence. He did not succeed in identifying any Communists working in the government. His widely scattered charges gave rise to a new word, *McCarthyism.* See McCarthyism.

McCarthy was elected to the Senate in 1946. He attracted national attention in 1950 by accusing the Department of State of harboring Communists. President Harry S. Truman, a Democrat, and Secretary of State Dean Acheson denied McCarthy's charges. But most of McCarthy's fellow senators of both parties were aware of his widespread support and were anxious to avoid challenging him. So was General Dwight D. Eisenhower, both as Republican presidential candidate and soon after becoming president in 1953. McCarthy also accused the Eisenhower Administration of treason.

A number of circumstances caused many Americans to believe McCarthy's charges. These included the frustrations of the Korean War (1950-1953), the Chinese Communist conquest of mainland China, and the conviction of several Americans as Soviet spies.

During nationally televised hearings in 1954, McCarthy accused the U.S. Army of "coddling Communists." The Army made countercharges of improper conduct by members of McCarthy's staff. As a result of the hearings, McCarthy lost the support of millions of people. The Senate condemned him in 1954 for "contemptuous" conduct toward a subcommittee that had investigated his finances in 1952, and for his abuse of a committee that recommended he be censured.

McCarthy was born on Nov. 14, 1908, in Grand Chute, Wisconsin, and graduated from Marquette University. He wrote *America's Retreat from Victory: The Story of George Catlett Marshall* (1951) and *McCarthyism: The Fight for America* (1952). Charles Bartlett

McCarthy, Mary (1912-1989), was an American author. She wrote novels, short stories, criticism, essays, travel books, and autobiography. Much of her work is satirical and deals with events and issues of the day.

Mary Therese McCarthy was born on June 21, 1912, in Seattle. She described her childhood and early life in *Memories of a Catholic Girlhood* (1957) and *How I Grew* (1987). McCarthy graduated from Vassar College in 1933 and served as drama critic for the *Partisan Review* from 1937 to 1948. Her reviews and other criticism from 1937 to 1956 were collected in *Sights and Spectacles* (1956) and *Theatre Chronicles* (1963).

McCarthy's fiction draws heavily on her own life. Her best-known novel, *The Group* (1963), follows the lives of several women who attended Vassar in the 1930's. Her other novels include *The Company She Keeps* (1942), *The Oasis* (1949), *The Groves of Academe* (1952), *A*

Charmed Life (1955), *Birds of America* (1971), and *Cannibals and Missionaries* (1979). Many of her short stories appear in *Cast a Cold Eye* (1950).

McCarthy wrote two travel books, *Venice Observed* (1956) and *The Stones of Florence* (1959). Her literary essays were collected in *On the Contrary* (1961), *The Writing on the Wall* (1970), and *Ideas and the Novel* (1980).

Barbara M. Perkins

McCarthyism is a term for the widespread accusations and investigations of suspected Communist activities in the United States during the 1950's. The word came from the name of Senator Joseph R. McCarthy. McCarthy, a Wisconsin Republican, made numerous charges—usually with little evidence—that certain public officials and other individuals were Communists or cooperated with Communists.

McCarthyism developed during the Cold War, a period of great hostility between the Communist and non-Communist nations. In the late 1940's and the 1950's, a number of events related to this struggle alarmed and frustrated many Americans. For example, Communists took over Czechoslovakia and China. The Soviet Union exploded its first atomic bomb and equipped the North Korean Communist forces that invaded South Korea. This invasion touched off the Korean War (1950-1953).

Meanwhile, charges that Americans had served as Soviet spies received wide attention. Alger Hiss, a former official of the U.S. Department of State, was accused of giving government secrets to a Soviet spy during the 1930's. Julius and Ethel Rosenberg, an American couple, were convicted of passing military secrets to Soviet agents in the 1940's. See **Hiss, Alger; Rosenberg, Julius and Ethel**.

As Communism appeared more and more threatening, the federal government began to search for secret Communists among its employees. In 1947, President Harry S. Truman established agencies called *loyalty boards* to investigate federal workers. Truman ordered the dismissal of any government employee whose loyalty appeared questionable. That same year, the U.S. attorney general established a list of organizations that the Department of Justice considered disloyal. Government agencies used the list as a guide to help determine the loyalty of employees and of people seeking jobs.

McCarthy first gained national attention in 1950, when he charged that Communists dominated the State Department. The Senate Foreign Relations Committee investigated the department but found no Communists or Communist sympathizers there. Nevertheless, McCarthy made numerous additional accusations and gained many followers. He and other conservatives blamed many of the nation's problems on the supposed secret presence of Communists in the government.

The accusations and investigations spread quickly and affected thousands of people. Librarians, college professors, entertainers, journalists, clergy, and others came under suspicion. Some firms *blacklisted* (refused to hire) people accused of Communist associations. Many employees, to keep their jobs, were required to take oaths of loyalty to the government. McCarthyism gradually declined after 1954. Among the factors that contributed to its decline were the end of the Korean War in 1953 and the condemnation of McCarthy by the Senate for conduct unbecoming a senator in 1954. In addition, from 1955 to 1958, the Supreme Court of the United States made a series of decisions that helped protect the rights of people accused of sympathizing with Communists. Today, the term *McCarthyism* is sometimes used to refer to reckless public accusations of disloyalty to the United States. Thomas C. Reeves

McCartney, Paul (1942-), is a famous English singer, songwriter, and musician. He first became prominent as a member of the Beatles, the most popular group in the history of rock music (see **Beatles**).

James Paul McCartney was born in Liverpool. He played bass with the Beatles. McCartney and guitarist John Lennon wrote most of the Beatles' music. With the Beatles, McCartney sang and wrote many of their melodic ballads. These ballads included "Yesterday" (1965), "Hey Jude" (1968), and "Let It Be" (1970). He also contributed some harder rock numbers, such as "I'm Down" (1965) and "Helter Skelter" (1968).

The Beatles disbanded in 1970. McCartney has continued to perform as a soloist. He formed Wings, a rock band that included his wife, Linda Eastman McCartney. His most popular albums since 1970 include *Band on the Run* (1973), *Tug of War* (1982), and *Flowers in the Dirt* (1989). He also composed a classical work, *Liverpool Oratorio* (1991), with the American composer Carl Davis. In 1997, he released *Flaming Pie,* an album that many critics considered one of his best since his work with the Beatles. McCartney was knighted in 1997. His poems and song lyrics were collected in 2001 as *Blackbird Singing: Poems and Lyrics 1965-1999.* Don McLeese

McCarty, Henry. See **Billy the Kid**.

McClellan, George Brinton (1826-1885), served for a time as the general in chief of the Union Army during the American Civil War (1861-1865). He was a brilliant organizer and trainer of troops and a scholar of military strategy. McClellan was called "Young Napoleon" after the famous French military genius Napoleon I. Some authorities rank McClellan as a great general, but most believe he was too cautious on the battlefield. In 1864, McClellan was the Democratic candidate for president. He lost to his Republican opponent, Abraham Lincoln.

Military career. At the outbreak of the Civil War, McClellan became a major general in command of Ohio volunteers. After becoming a major general in the regular army, he cleared western Virginia of Confederate forces. In the summer of 1861, he took command of the Union Army in the East, which became known as the Army of the Potomac. In November 1861, he became general in chief of all armies. President Lincoln grew impatient because McClellan did not move against the Confederates. He relieved him as supreme general in March 1862. McClellan remained an Army commander.

McClellan finally advanced in the spring of 1862, moving against Richmond from the east in the Peninsular Campaign. After fighting at Williamsburg and Fair Oaks, he drew close to Richmond. The Confederates, under General Robert E. Lee, then attacked him in the Battles of the Seven Days and drove him back to Harrison's Landing on the James River. Washington authorities then transferred his army to northern Virginia, uniting most of his troops temporarily with a force under General John Pope's command. After Pope's defeat at the Second

Battle of Bull Run, or Manassas, McClellan became head of all troops in the Washington area.

McClellan led his army into Maryland to meet a Confederate invasion. The two armies clashed in the Battle of Antietam on Sept. 17, 1862, the bloodiest day of the war. About 12,500 Northerners and almost 11,000 Southerners were killed or wounded in the battle. McClellan forced the Confederates to retreat, but he did not immediately pursue them. His delay angered Lincoln. Lincoln replaced McClellan with General Ambrose Burnside in November 1862, and McClellan's military career ended.

Other activities. McClellan was born on Dec. 3, 1826, in Philadelphia. He graduated from the U.S. Military Academy in 1846, second in his class. He served in the Mexican War (1846-1848) and went to Europe in 1855 to study European military systems. In 1857, McClellan became chief engineer of the Illinois Central Railroad. He became vice president of that railroad, and later served as president of a division of the Ohio and Mississippi Railroad. McClellan was governor of New Jersey from 1878 to 1881. Gabor S. Boritt

McClintock, Barbara (1902-1992), an American geneticist, won the 1983 Nobel Prize for physiology or medicine. She received the award for her discovery that certain genes can change their position on the chromosomes of cells. These genes, called *mobile genetic elements,* occur in all organisms.

McClintock studied the way corn inherits its traits. In 1931, she showed that different chromosomes can break and exchange parts during the formation of eggs or sperm. This process is important because it allows each egg and sperm to contain a different combination of genes. In 1951, McClintock announced her discovery of mobile genetic elements. In some corn plants, the mobile gene might be in one place on a chromosome, but in others it would be somewhere else. McClintock could tell where the mobile gene was because of its effects on nearby genes.

McClintock was born on June 16, 1902, in Hartford, Connecticut. She received a Ph.D. degree from Cornell University in 1927. She became a member of the Carnegie Institution of Washington, D.C., in 1941.
Daniel L. Hartl

McCloskey, John Cardinal (1810-1885), was the first American to be named a cardinal of the Roman Catholic Church. He served as the second archbishop of the Roman Catholic archdiocese of New York from 1864 until his death. Pope Pius IX named him a cardinal in 1875 despite McCloskey's opposition to the definition of papal infallibility at Vatican Council I.

McCloskey was born on March 10, 1810, in New York City. He was ordained a priest in 1834 and a bishop in 1844. From 1847 to 1864, he served as the first bishop of Albany, New York. There he helped reduce widespread anti-Catholic sentiment and oversaw the building of new schools and churches. As archbishop, he saw to the needs of thousands of immigrants. He also supervised the completion of St. Patrick's Cathedral in New York City. David G. Schultenover

McClung, Nellie (1873-1951), was a leading Canadian feminist and an author. She fought successfully for political and legal rights for Canadian women. In 1912, she helped found the Winnipeg (Manitoba) Political Equality League, which campaigned for female *suffrage* (voting rights) in Canada. Manitoba was one of several provinces that in 1916 gave women the right to vote. Female suffrage became nationwide in 1918.

From 1921 to 1926, McClung served in the Alberta legislature. She was one of five women who began a court battle in 1927 to determine whether women were "persons" under the British North America Act, which then served as Canada's constitution. The Privy Council in England, the highest judicial authority in the British Empire, ruled in their favor in 1929. This enabled women to serve in the Canadian Senate.

McClung wrote several books about Canadian life and the women's movement, including *In Times Like These* (1915) and *Purple Springs* (1921). Nellie Letitia McClung was born on Oct. 20, 1873, in Chatsworth, Ontario.
Patricia Monk

McClure, Sir Robert John Le Mesurier (1807-1873), also spelled *M'Clure,* was a British explorer who led the first expedition to cross the Northwest Passage. He discovered the route through the Arctic region while on an expedition from 1850 to 1854. McClure was searching for Sir John Franklin, a British explorer who had not returned from a voyage begun in 1845. McClure sailed across the Beaufort Sea and around Banks Island, where his ship became stuck in ice. McClure and his crew almost starved to death but were rescued in 1853. McClure then covered the rest of the passage, traveling by ship and sled to Baffin Bay. After returning to the United Kingdom in 1854, McClure was knighted and promoted to captain in the Royal Navy. He was born on Jan. 28, 1807, in Wexford, Ireland. He joined the Navy in 1824. See also Northwest Passage. Barry M. Gough

McClure, Samuel Sidney (1857-1949), was an American editor and publisher. He founded the McClure Syndicate in New York City in 1884. This was one of the first newspaper syndicates. In 1893, he founded *McClure's Magazine,* one of the first successful inexpensive magazines. McClure became a leader in *muckraking* (exposing dishonesty). He was briefly connected with the S. S. McClure Newspaper Corporation, which was formed in 1915 when he bought the *New York Mail.* McClure was born on Feb. 17, 1857, in Forcess, Ireland. His works include *My Autobiography, Obstacles to Peace,* and *The Achievements of Liberty.* Joseph P. McKerns

McConnell Family Foundation is the largest private foundation in Canada. It seeks to advance the quality of life in Canada through grants and awards to not-for-profit organizations that help solve cultural, educational, environmental, health, or social problems.

Programs funded by the foundation include those that (1) promote the artistic development of people seeking to become professional artists; (2) provide alternatives to institutional living for elderly or disabled people; (3) increase public awareness of environmental issues; (4) aid rural communities, homeless people, or disadvantaged youth; or (5) help not-for-profit companies improve their

management and fund-raising skills. The foundation makes grants only to nonprofit organizations and only for clearly charitable purposes. It does not make grants to individuals.

In 1937, John Wilson McConnell, a Canadian financier, set up the J. W. McConnell Foundation. In 1966, that organization established the Griffith Foundation. In 1987, the two foundations combined to form the J. W. McConnell Family Foundation, with headquarters in Montreal. For assets, see **Foundations** (table).

McCord, David (1897-1997), an American writer, was best known for his poetry for young children. He wrote humorous poems filled with imaginative wordplay that emphasizes the sounds and rhythms of language. Many of his poems are about small animals and children.

McCord wrote several books of poetry for children. Five of the books were collected in *One at a Time* (1977). His other books of poetry include *Every Time I Climb a Tree* (1967), *The Star in the Pail* (1975), and *Speak Up: More Rhymes of the Never Was and Always Is* (1980).

David Thompson Watson McCord was born in New York City. McCord was also a painter and taught creative writing. Nancy Lyman Huse

McCormack, John (1884-1945), was perhaps the most famous of Irish tenors. His popularity as a concert artist was almost unrivaled. It enabled him to amass a fortune. McCormack commanded a light, clear voice and sang with perfect diction and great vocal finesse. He sang airs of the 1700's and Irish ballads with equal eloquence.

McCormack began his career at the age of 18 by winning a gold medal at the National Irish Festival in Dublin. After study in Italy, he won immediate success in Naples, London, New York, Boston, and Chicago. McCormack abandoned opera after 1913 in favor of concerts. He was born in Athlone, Ireland, but became a U.S. citizen in 1917. Martin Bernheimer

McCormack, John William (1891-1980), a Democrat from Massachusetts, served as speaker of the United States House of Representatives from 1962 to 1971. Before his election as speaker, McCormack had been deputy to Sam Rayburn, the top House Democrat from 1940 until his death in 1961.

McCormack was born in Boston and attended public schools there. He served in the Massachusetts legislature from 1920 to 1926 and represented his South Boston district in the U.S. House of Representatives from 1928 to 1971. McCormack gained a reputation in Congress as a strong supporter of his party's legislative programs. In 1969, a group of liberal House Democrats tried to replace McCormack as speaker, but he was reelected by a wide margin. McCormack retired from the House in January 1971. Charles Bartlett

McCormick, Cyrus Hall (1809-1884), invented a reaping machine that revolutionized grain harvesting in the United States. His horse-drawn reaper enabled farmers to harvest more than 10 acres (4 hectares) of grain per day. Before his invention, farmers harvested with cradle scythes and a skilled worker could harvest at most 2 or 3 acres (0.8 to 1.2 hectares) per day.

McCormick was born on a farm in Rockbridge County, Virginia. As a youth, he experimented with various tools in the hope of designing equipment that would simplify farmers' work. He also observed his father's unsuccessful efforts to construct a mechanical reaper. In 1831, Cyrus built his first reaper. He tested the device on wheat and oats and continued to make adjustments before patenting it in 1834. McCormick finally offered his reaper for sale in Virginia in 1840.

The reaper sold well, and McCormick expanded sales to other parts of the country in 1844. Sales boomed because the machine's efficiency enabled farmers to raise more grain and greatly increase their income.

In 1847, McCormick moved his manufacturing operation to Chicago to increase sales. Centrally located in the Midwest, he used the Great Lakes to transport reapers to the Eastern States, and the Mississippi River to ship reapers into the South. McCormick gained worldwide fame in 1851, when he demonstrated his machine at an exhibition in London. By late 1851, Chicago newspapers boasted that the McCormick Harvesting Machine Company was the largest implement factory in the world. Its sales and distribution grew further in the 1850's, when Chicago became a major railroad center.

McCormick remained president of the McCormick Harvesting Machine Company until his death. In 1902, the firm merged with four other implement companies to form the International Harvester Company (now Navistar International Corporation). R. Douglas Hurt

See also **Reaper**.

McCormick, Robert Rutherford (1880-1955), an American editor and publisher, made the *Chicago Tribune* one of the nation's most important newspapers. His grandfather Joseph Medill gave the *Tribune* its first fame (see **Medill, Joseph**). With his cousin Joseph Medill Patterson, McCormick built an enterprise that included the *Tribune*, the New York *Daily News*, and the *Washington* (D.C.) *Times-Herald*. He took over sole control of the *Tribune* in 1925. A conservative Republican, McCormick fought the New Deal (see **New Deal**). He was born in Chicago. Joseph P. McKerns

McCoy, Elijah, *ih LY juh* (1843-1929), was a black American engineer and inventor who developed the automatic lubricator. His invention, the *lubricator cup*, continuously supplies lubricants to moving parts of various types of machines.

Before McCoy's invention during the early 1870's, workers had to lubricate machine parts regularly. The lubricator cup automatically oils machine parts as they operate, and has eliminated the need for such workers. Throughout his life, McCoy worked to improve lubricating systems for locomotives and other machines. The expression *the real McCoy*, meaning *the real thing*, may have originated with machinery buyers who insisted that their new equipment have only McCoy lubricators.

McCoy was born in Colchester, Ontario. His parents had been slaves who fled to Canada from Kentucky. McCoy was apprenticed to a mechanical engineer in Scotland and later worked as a fireman-oilman for several railroads in Michigan. W. Bernard Carlson

McCrae, *muh KRAY,* **John** (1872-1918), was a Canadian physician, soldier, and poet. He contributed verses to Canadian periodicals before World War I. But he did not become famous until 1915 when he published "In Flanders Fields" in *Punch*, an English magazine.

McCrae's poems were published after his death under the title *In Flanders Fields, and Other Poems* (1919).

The second stanza of his famous poem is:

> We are the Dead. Short days ago
> We lived, felt dawn, saw sunset glow,
> Loved and were loved, and now we lie
> In Flanders fields. Reprinted by permission of *Punch*

McCrae was born on Nov. 30, 1872, in Guelph, Ontario. After serving in the Canadian Army in South Africa, he became a pathologist at McGill University and at Montreal General Hospital. As the chief medical officer at a hospital in Boulogne, France, in World War I, he saw the suffering and death he wrote about. He died of pneumonia before the war ended. Rosemary Sullivan

McCullers, Carson (1917-1967), was an American novelist known for her stories of small-town life in the South. Many of her characters are lonely, disappointed people. McCullers was particularly interested in adolescents who learn the meaning of loneliness while appearing to be part of a close family. *The Member of the Wedding* (1946) portrays a 12-year-old girl experiencing the pains of growing up. Her other major themes include the search for individual identity, the nature of love, and the inevitability of death.

Many characters in McCullers's books are lonely because they are deformed. For example, two characters in her short novel *The Ballad of the Sad Café* (1951) are a dwarf and an abnormally large woman. Her other novels—*The Heart Is a Lonely Hunter* (1940), *Reflections in a Golden Eye* (1941), and *Clock Without Hands* (1961)—show the violence and pain that may accompany loneliness and lack of love. McCullers wrote two plays—an adaptation of *The Member of the Wedding* (1950) and *The Square Root of Wonderful* (1957). *The Mortgaged Heart* (1971) contains essays, poems, and early fiction. Her *Collected Stories* was published in 1987, after her death. McCullers was born on Feb. 19, 1917, in Columbus, Georgia. Her real name was Lula Carson Smith. She married James Reeves McCullers, Jr., in 1937.
Noel Polk

McCulloch v. Maryland resulted in one of the most important decisions in the history of the Supreme Court of the United States. The court ruled in 1819 that Congress has implied powers in addition to those specified in the Constitution. The decision was based on a section of the Constitution called the "necessary and proper" clause. This clause gives Congress power "to make all laws which shall be necessary and proper" to carry out its other powers. The court also ruled that when federal and state powers conflict, federal powers prevail.

James McCulloch, cashier of the Baltimore branch of the Bank of the United States, refused to pay a Maryland state tax on the bank. The court first upheld the implied power of Congress to create a bank, because Congress needed a bank to exercise its specified powers. It then declared the tax unconstitutional because it interfered with an instrument of the federal government. In one of his most famous opinions, Chief Justice John Marshall said that the American people "did not design to make their government dependent on the states."
Gregg Ivers

McDonald's Corporation operates one of the world's largest chains of fast-food restaurants. McDonald's has over 26,000 restaurants in about 120 countries.

McDonald's was founded in 1955 by Ray Kroc, a distributor of machines for making milk shakes. Kroc learned of a California hamburger stand that had eight of the machines. Kroc visited the stand, which was called McDonald's, and was impressed with how quickly customers were served. Kroc persuaded the stand's owners to let him start a chain of fast-service restaurants of the same name. Kroc opened the first McDonald's restaurant in Des Plaines, Illinois, in 1955.

A clown named Ronald McDonald serves as a corporate spokesperson for McDonald's restaurants. McDonald's Corporation sponsors Ronald McDonald House Charities. This organization operates over 200 Ronald McDonald Houses worldwide in which the families of critically ill children may stay when the young patients undergo medical treatment away from their homes.

McDonald's Corporation has headquarters in Oak Brook, Illinois. In addition to McDonald's restaurants, the corporation operates restaurants under the names Aroma Café, Boston Market, Chipotle Mexican Grill, and Donatos Pizza. Critically reviewed by McDonald's Corporation

McEnroe, John (1959-), became one of the world's best tennis players. He won the U.S. Open singles title in 1979, 1980, 1981, and 1984 and the All-England (Wimbledon) singles championship in 1981, 1983, and 1984. With Peter Fleming, he won the Wimbledon doubles title in 1979, 1981, 1983, and 1984 and the U.S. doubles title in 1979, 1981, and 1983. McEnroe also won the 1992 Wimbledon doubles championship with Michael Stich of Germany.

© Sh. Steiner, Sygma
John McEnroe

McEnroe, a left-hander, became noted for his powerful serve and quickness. McEnroe stirred much controversy for his frequent conflicts with officials during matches.

John Patrick McEnroe was born on Feb. 16, 1959, in Wiesbaden, Germany, where his father was serving in the U.S. Air Force. McEnroe turned professional in 1978. Arthur Ashe

McGill, James (1744-1813), a wealthy Canadian merchant known for his *philanthropy* (charity), founded McGill University in Montreal, Quebec. Born on Oct. 6, 1744, in Glasgow, Scotland, McGill settled in Montreal in 1770 and made a fortune in the fur trade. He willed money and land for the establishment of McGill University, which was chartered in 1821 and opened in 1829.
D. Peter MacLeod

McGill University is a coeducational university in Montreal, Canada. It is supported chiefly by the province of Quebec. Courses are conducted in English, though Montreal is primarily a French-speaking city.

The university offers programs in architecture, arts, computer science, dentistry, education, engineering, law, library science and information studies, management, medicine, music, nursing, physical and occupational therapy, religious studies, science, social work, and urban planning. It grants bachelor's, master's, and doctor's degrees. The university has a division of agri-

culture and a school of dietetics and human nutrition in nearby Ste.-Anne-de-Bellevue. It operates a subarctic research laboratory in Schefferville, Quebec, an institute for research in the natural sciences in Mont-St.-Hilaire, Quebec, and a facility in Barbados for research on tropical animals, plants, geography, and geology.

James McGill, a Canadian merchant, willed money and land to set up the university. It was chartered in 1821 and opened in 1829.

McGillicuddy, Cornelius. See Mack, Connie.

McGillivray, Alexander (1759?-1793), was an influential Creek Indian leader around the time of the Revolutionary War in America (1775-1783). He helped protect Creek lands from American settlers.

McGillivray was born near what is now Montgomery, Alabama. His father was a wealthy Scot, and his mother was half Creek and half French. McGillivray believed an independent United States would threaten Indian lands. He helped keep the Creeks loyal to the British during the Revolutionary War. McGillivray and his Creek warriors fought wars with Georgia and Tennessee from 1785 to 1787. In 1790, he signed a treaty with the United States that guaranteed the Creeks certain territory where settlement by U.S. citizens was prohibited.

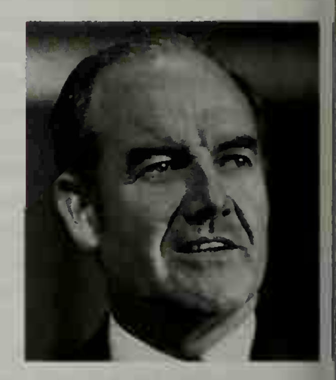
McGillivray worked hard to unite the Creeks under a strong central government. He called for changes in the way the Creeks viewed politics, but he died before the Creeks carried out his reforms. The Creeks adopted many of his ideas in the 1820's. Michael D. Green

McGillivray, William (1764?-1825), served as director of the North West Company, in what is now Canada, from 1804 to 1821. This company, a fur-trading organization, consisted of a collection of Montreal fur-trading firms.

McGillivray was born in the county of Inverness-shire in Scotland. He settled in Montreal in 1784 and went to work as a clerk for the North West Company. In 1786, McGillivray took charge of a trading post for the firm. He became a partner in the firm in 1790.

McGillivray helped develop the fur trade by sending traders into wilderness regions of western Canada. In 1821, he realized that the North West Company could not compete with the Hudson's Bay Company, a British fur-trading firm. He helped unite the two firms under the name of the Hudson's Bay Company. P. B. Waite

McGinley, Phyllis (1905-1978), was a leading American author of light verse. Her collection *Times Three: Selected Verse from Three Decades* won the 1961 Pulitzer Prize for poetry.



McGinley praised the virtues of the ordinary life with affection and humor, and she celebrated but also satirized life's absurdities. She defended femininity, morality, and domestic and suburban living in *Times Three* and in two books of witty essays, *The Province of the Heart* (1959) and *Sixpence in Her Shoe* (1964). McGinley summed up her point of view by quoting a man who said he had failed as a philosopher because "cheerfulness was always breaking in." She wrote many books for young people, including *The Horse Who Lived Upstairs* (1944) and *Sugar and Spice* (1960).

McGinley was born in Ontario, Oregon. She lived in a suburb of New York City, which provided the setting for much of her writing. Bonnie Costello

McGovern, George Stanley (1922-), was the Democratic presidential nominee in 1972. He lost to his Republican opponent, President Richard M. Nixon.

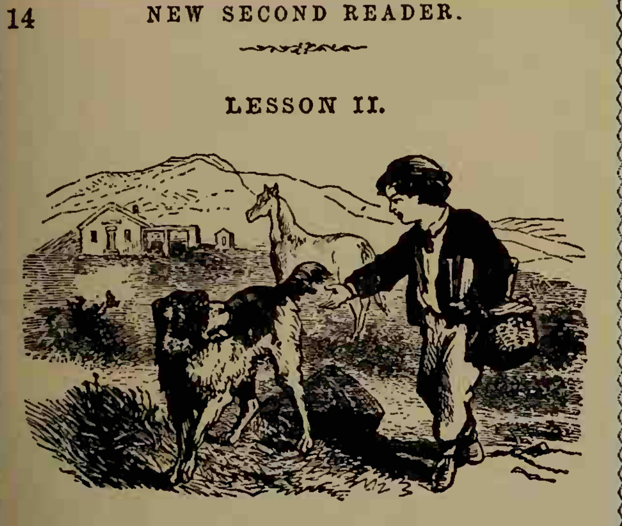
When McGovern ran for president, he was serving his second term as a U.S. senator. In 1962, he had been elected South Dakota's first Democratic senator since the 1930's. During the 1950's, he twice won election to the U.S. House of Representatives.

Early life. McGovern was born on July 19, 1922, in Avon, South Dakota. He graduated from Dakota Wesleyan University and later taught history there. He earned a master's degree and a Ph.D. at Northwestern University. During World War II (1939-1945), McGovern served as a bomber pilot and won the Distinguished Flying Cross. In 1943, he married Eleanor Faye Stegeberg. The McGoverns had five children—from oldest to youngest, Ann, Susan, Teresa, Steven, and Mary.

George S. McGovern

Career in Congress. McGovern was elected to the U.S. House of Representatives in 1956. He was reelected in 1958 and ran unsuccessfully for the U.S. Senate two years later. McGovern won election to the Senate in 1962 and was reelected in 1968. In 1969, McGovern became chairman of a commission to recommend ways to reform the Democratic Party. In 1974, McGovern won reelection to a third term in the Senate, but he was defeated in his bid for a fourth term in 1980.

Presidential candidate. In 1972, the Democratic National Convention nominated McGovern for president and Senator Thomas F. Eagleton of Missouri for vice president. Twelve days after Eagleton's nomination, he revealed that he had been hospitalized three times in the 1960's for treatment of emotional exhaustion and depression. Eagleton's qualifications for the vice presidency became the subject of a nationwide debate, and he resigned from the ticket at McGovern's request.



Eagleton was replaced by Sargent Shriver, who was a former director of the Peace Corps. McGovern and Shriver were defeated by Nixon and Vice President Spiro T. Agnew. For the electoral vote, see **Electoral College** (table).

McGovern also ran for the 1984 Democratic presidential nomination. He withdrew from the race after failing to win any early primary elections. In 1998, he became the United States representative to the United Nations Food and Agriculture Organization. David S. Broder

McGuffey, William Holmes (1800-1873), was an American educator and clergyman. From 1836 to 1857, he published illustrated reading books. More than 120 million copies of his *Eclectic Readers* were sold, and for many years nearly all American schoolchildren learned to read from them. The books did much to form American moral ideas and literary tastes in the 1800's.

McGuffey was born in Washington County, Pennsyl-

vania. He became a Presbyterian minister in 1829. He taught at Miami University in Ohio and at the University of Virginia. He was president of Ohio University from 1839 to 1845. Glenn Smith

McGwire, Mark (1963-), was one of the greatest home-run hitters in baseball history. McGwire set a major league home-run record when he hit 70 home runs during the 1998 baseball season. He broke the record of 61 home runs set by Roger Maris of the New York Yankees in 1961. The record was broken in 2001 by Barry Bonds, who hit 73 home runs. McGwire retired after the 2001 season with 583 home runs.

McGwire and Sammy Sosa are the only players to hit at least 50 home runs in four consecutive seasons. McGwire hit 52 home runs in 1996, 58 in 1997, 70 in 1998, and 65 in 1999. He led the National League in runs batted in for the 1999 season with 147.

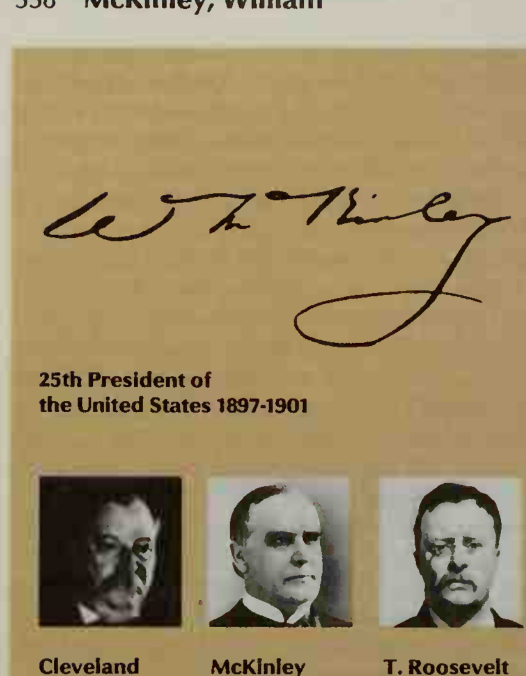
Mark David McGwire was born in Pomona, California. He attended the University of Southern California and was named national college player of the year in 1984. That year, McGwire was drafted by the Oakland Athletics of the American League. He played in the minor leagues for two years before joining Oakland late in the 1986 season. McGwire set a major league record for home runs by a rookie with 49 and was named American League Rookie of the Year. Oakland traded McGwire to the St. Louis Cardinals of the National League during the 1997 season. Dave Nightingale

McHenry, *muhk HEHN ree,* **James** (1753-1816), a doctor and politician, was a Maryland signer of the Constitution of the United States. He was absent from many early sessions of the Constitutional Convention in 1787 but helped shape the final document. He helped win *ratification* (approval) of the Constitution by Maryland.

McHenry was born in Ballymena, Ireland. He moved to Philadelphia in 1771 and studied medicine. During the Revolutionary War in America (1775-1783), McHenry served as an army surgeon and as secretary to General George Washington and the Marquis de Lafayette. He served in the Maryland legislature from 1781 to 1786 and from 1791 to 1796, and he attended the Congress of the Confederation from 1783 to 1785. In 1796, President George Washington appointed him secretary of war. McHenry continued in this office under President John Adams until 1800. Joan R. Gundersen

McKay, Claude (1890-1948), was a black poet and novelist. His poetry is noted for its lyricism and its powerful statements of black militancy. The best known of McKay's three novels is *Home to Harlem* (1928), the story of a black American soldier's life after his return from France after World War I (1914-1918). Some black critics protested that it emphasized exotic elements in black life but ignored the major problems of African Americans. McKay's 10 other books include *Harlem Shadows* (1922), a collection of poems; *Banana Bottom* (1933), a novel; *A Long Way from Home* (1937), an autobiography; and *Selected Poems* (published in 1953, after his death).

McKay was born in Jamaica. He moved to the United States in 1912 to attend college. William L. Andrews



See also American literature (The Harlem Renaissance).

McKay, Donald (1810-1880), was a Canadian master craftsman who designed and built more than 90 clipper ships. Famed for grace and seaworthiness, they were the fastest sailing vessels ever built. The *Flying Cloud,* launched in 1851, sailed around Cape Horn from New York to San Francisco in 89 days. It covered 374 nautical miles (693 kilometers) in one day. Both the speed of the cruise and the length of the day's run set world sailing records. McKay launched the *Great Republic,* the largest wooden sailing ship ever built, in 1853. It measured 335 feet (102 meters) in length. McKay built most of his ships in Boston. He was born in Shelbourne County, Nova Scotia. See also Ship (Clipper ships). James C. Bradford

McKean, *muh KEEN,* **Thomas** (1734-1817), an American statesman, was a Delaware signer of the Declaration of Independence. He was a Delaware delegate to the Continental Congress and the Congress of the Confederation almost continuously from 1774 to 1783. McKean also served as chief justice of Pennsylvania from 1777 to 1799. He was governor of that state from 1799 to 1808.

McKean was born in New London, Pennsylvania. He studied law and, in 1776, wrote most of the Delaware state Constitution. James H. Hutson

McKinley, William (1843-1901), helped shape the modern presidency and set the United States on a path toward world leadership. During his two Administrations, the nation emerged from a depression. American soldiers and sailors won the Spanish-American War (1898). The United States took possession of Guam, Hawaii, the Philippines, Puerto Rico, and part of American Samoa. Victory at war and control of new lands made the United States a world power, and thus also increased the power of the presidency.

McKinley led the Republican Party during the 1890's. He supported his party's belief in *protective tariffs,* taxes on imports to protect American industries from foreign competition. He and his party also promoted the growth of big business in the United States. McKinley succeeded President Grover Cleveland and twice defeated the well-known statesman William Jennings Bryan for the presidency. An assassin shot and killed McKinley about six months after the start of his second term, and Vice President Theodore Roosevelt became President. McKinley was the third President to be assassinated. The first two were Abraham Lincoln and James A. Garfield.

Following the hard times of the mid-1890's, McKinley's two Administrations were filled with national optimism and confidence. The motion picture, the automobile, and the telephone were becoming part of everyday life. Businesses were growing, but social problems remained. Blacks faced segregation, violence, and lynchings in the South. Industrial workers labored an average of 59 hours a week. And women had full voting rights in only four states—Colorado, Idaho, Utah, and Wyoming. There were already stirrings of a spirit of reform that would sweep through the United States after 1901.

History has not been kind to McKinley. Historians and political scientists have often underestimated his achievements as President. They have seen McKinley as a colorless, cautious President compared with more exciting leaders, such as Theodore Roosevelt and Woodrow Wilson. In fact, McKinley's presidency was a time of great change for the nation, and he did much to shape that change. He strengthened the powers of his office and expanded the nation's role in world affairs.

Early life

Childhood. William McKinley was born on Jan. 29, 1843, in Niles, Ohio, a rural town with a population of about 300. His parents, William, Sr., and Nancy McKinley, owned an iron foundry. His grandfather James McKinley had moved to Ohio in the early 1800's to manage an iron foundry in Columbiana County.

Education. William, the seventh of nine children, attended school in Niles. When William was 9 years old, the family moved to Poland, Ohio, near Youngstown, in search of better schools. The boy entered a private school, the Poland Seminary. McKinley's father stayed in Niles to run his iron foundry, spending much time away from the family. At the age of 10, McKinley joined the Methodist Episcopal Church. When he was 17, he entered Allegheny College in Meadville, Pa. But he soon became ill and dropped out.

Bravery under fire. When the Civil War began in 1861, McKinley was the first man in the town of Poland to volunteer to fight. He joined the 23rd Ohio Infantry commanded by future U.S. President Rutherford B. Hayes. At the Battle of Antietam in 1862, McKinley brought food to his regiment while it was under intense enemy assault. This bravery under fire helped earn him a promotion to second lieutenant. He ended the war

The explosion of the U.S. battleship *Maine* on Feb. 15, 1898, in Havana helped trigger the Spanish-American War.

The Klondike gold rush attracted thousands of fortune hunters to the Yukon Territory of Canada in the late 1890's.

The world of President McKinley

Press sensationalism arose during the late 1800's, as newspapers competed for readers. William Randolph Hearst's *New York Journal* and Joseph Pulitzer's *New York World* battled for public attention with sensational headlines and exaggerated reporting that became known as "yellow journalism."
Hawaii, Puerto Rico, and the Philippines became American possessions between 1898 and 1900.
Spanish-American War heroes came home to public acclaim. Admiral George Dewey was the hero of the Battle of Manila. Theodore Roosevelt captured national attention as a commander of the Rough Rider Regiment that helped defeat Spanish forces at the Battle of San Juan Hill in Cuba.
Walter Reed, a U.S. Army doctor, conducted experiments in Cuba during the Spanish-American War that led to important advances in the control of typhoid and yellow fever.
Marie and Pierre Curie of France discovered the elements radium and polonium in 1898 while studying the radioactive properties of uranium.
The Boer War broke out in South Africa in 1899. British and mainly Dutch forces fought for control of territory.
Temperance crusader Carry Nation began smashing saloons in Kansas in 1899. Her efforts helped bring about national prohibition 20 years later.
The Boxer Rebellion erupted in China in 1900. Chinese nationalists who opposed the spread of Western influence in China battled Europeans and Chinese Christians.
The first Texas oil strike occurred on Jan. 10, 1901, when oil was found at the Spindletop oil field near Beaumont.

with the rank of *brevet* (honorary) major. Later, during his political career, he was known as Major McKinley.

After the war ended in 1865, McKinley studied law. He worked for a county judge in Youngstown for about 18 months. In 1866, he entered law school in Albany, N.Y. In 1867, he began practicing law in Canton, Ohio.

Political and public activities

Entry into politics. McKinley was a gifted public speaker and a naturally popular figure in the community. He began his political career in 1869, when he was elected prosecuting attorney of Stark County, Ohio. McKinley narrowly lost reelection in 1871.

McKinley's family. On Jan. 25, 1871, McKinley married Ida Saxton (June 8, 1847-May 26, 1907), whose grandfather had founded the first newspaper in Canton. The McKinleys had two daughters. In 1873, the younger one died when she was 4 months old. That same year, Mrs. McKinley's mother died. Two years later, the McKinleys' other daughter, Katherine (1871-1875), died. The grief and shock caused by these deaths left Ida an invalid. Later, she developed epilepsy.

Congressman. McKinley won election to the U.S. House of Representatives in 1876. He served seven terms, from 1877 to 1891, except for about 9 months in 1884-1885. In 1884, the House ruled that McKinley's opponent, lawyer Jonathan H. Wallace, had actually received the most votes in the 1882 election. Wallace took McKinley's seat for the rest of the term, but McKinley returned to Congress in 1885 with a clear victory in the 1884 election.

In Congress during the late 1870's, McKinley voted for *free silver.* Free silver was a plan to increase the country's supply of money by allowing the treasury to mint silver coins in addition to gold coins. See Free silver.

McKinley also gained fame as a strong supporter in Congress of the protective tariff. The protective tariff is a policy, he said, that believes "in American work for

William McKinley's birthplace was this frame building on South Main Street in Niles, Ohio. The building was later moved and then was destroyed by fire in 1937.

American workmen, that believes in American wages for American laborers, that believes in American homes for American citizens." The McKinley Tariff Act of 1890 raised taxes on imports to a record high and supported trade agreements with Latin-American countries.

Governor. In 1890, McKinley lost his bid for an eighth term in Congress. This loss came in part because the McKinley Tariff had greatly increased consumer prices and so became unpopular. In addition, the Democrats had *gerrymandered* (unfairly redrawn the boundaries of) his district. In 1891, however, voters elected McKinley governor of Ohio. McKinley improved the state's canals, roads, and public institutions. He also established a state board to settle labor disputes.

As McKinley's national reputation grew, people began to consider him for the presidency. In addition, McKinley had become friends with Cleveland businessman and millionaire Mark Hanna. Legend describes Hanna as leading McKinley to political power and success. But in fact, McKinley used Hanna to meet his own political goals. In 1892, Hanna opened an unofficial McKinley-for-President headquarters at the Republican National Convention in Minneapolis, Minn. McKinley received a flurry of support for the nomination. In balloting at the convention, he accumulated 182 votes but lost to President Benjamin Harrison, who got 535 votes.

Crisis and triumph. In 1893, McKinley faced a personal crisis that almost sidetracked his political career. He had co-signed bank notes totaling more than $100,000 to help a friend start a business manufacturing tin plate. But the business failed, and McKinley was expected to repay the bank loans. McKinley did not have the money. His friends, led by Hanna, raised enough funds to pay the obligation. The public sympathized with McKinley and reelected him governor in 1893.

As the 1896 presidential election approached, people again supported McKinley for President. His popularity within the party and an absence of strong rivals led to his nomination at the Republican National Convention in St. Louis, Mo. The Republicans chose Garret A. Hobart of New Jersey to run as Vice President.

The Democrats nominated the great orator William Jennings Bryan of Nebraska as McKinley's opponent. Bryan chose Arthur Sewall, a wealthy Maine shipbuilder, as his running mate.

The front-porch campaign. McKinley stayed in Canton during the campaign and spoke to visiting delegations from his front porch. More than 750,000 people visited Canton to hear him speak. Newspapers nationwide reprinted his speeches. As McKinley's campaign manager, Hanna helped raise some $3½ million in campaign funds from banks and other businesses.

McKinley had wanted to stress the protective tariff as the campaign theme. But Bryan electrified the Democratic National Convention with his "cross of gold" speech in favor of free silver. Bryan's appeal for an unlimited number of silver coins made currency the main issue. McKinley no longer supported free silver as he did in Congress. Instead, he called for the United States to maintain the *gold standard,* a system in which the dollar was defined as worth a certain quantity of gold. He also proposed higher tariffs. McKinley told voters that free silver would increase consumer prices, but that high tariffs would promote national prosperity. In the November election, McKinley won with more than 7 million of the nearly 14 million votes.

McKinley's first Administration (1897-1901)

McKinley took office on March 4, 1897. His first priority was to increase the protective tariff. He called Congress into special session, and the Dingley Tariff of 1897 was passed. This act raised taxes on imports to record highs. Three years later, Congress passed the Gold Standard Act of 1900. This act made only gold—not silver—exchangeable for money in the United States.

McKinley developed new policies toward the press that laid the basis for modern techniques of informing the public about the President. McKinley's secretary, George B. Cortelyou, adopted new procedures for distributing press releases and conducting presidential travel. Also, McKinley made himself accessible to the press corps and provided space in the White House where reporters could work.

The Spanish-American War (1898). In 1895, Cubans began a rebellion against Spain, which had ruled Cuba for almost 400 years. After McKinley took office in 1897, he pressed Spain to negotiate with the rebels. The new President had wanted to remain neutral in the affair. However, McKinley said that the United States would go

to war if necessary to protect U.S. interests.

On Feb. 15, 1898, the battleship U.S.S. *Maine* exploded in Havana harbor in Cuba. Today, historians believe the explosion was an accident. But at the time, the public blamed Spain. Many politicians, newspaper publishers, and those in favor of expanding U.S. territorial control urged McKinley to help Cuba. He hoped the Spaniards would peacefully leave the island. But no Spanish politician could accept the loss of Cuba and remain in power.

Greatly pressured by public opinion, McKinley asked Congress for authority to take action. On April 25, the United States declared war on Spain. U.S. Army and Navy troops overpowered Spanish forces. Key battles took place in the Philippines and off the coast of Cuba. In July, the Spanish forces in Cuba surrendered. In August, an armistice ended the fighting. On December 10, Spain and the United States signed the Treaty of Paris. Under this agreement, Spain surrendered Guam and Puerto Rico to the United States. It also gave the United States the Philippines for $20 million. See **Spanish-American War.**

America becomes a world power. The war with Spain lasted only 113 days, but it had far-reaching effects. As a result of the conflict, the United States took over most of Spain's overseas territories, leaving it with only a few outposts in northern Africa. Also in 1898, the United States took possession of what had been the Republic of Hawaii. In 1899, the United States signed a treaty with Germany and the United Kingdom, gaining what is now part of American Samoa. Because of its new possessions in the Pacific Ocean, the United States became more involved in Asian politics.

In February 1899, a Filipino patriot named Emilio Aguinaldo led a revolt against American control of the Philippines. The rebels waged *guerrilla warfare,* which involved small-scale hit-and-run attacks, for over three years. To defeat the guerrillas, U.S. soldiers used cruel tactics, including the killing of civilians. As a result, many Americans turned against U.S. *imperialism* (controlling territories for political or economic gain).

The United States also used military force in China. In 1899, McKinley's secretary of state, John M. Hay, issued what became known as the Open-Door Policy. This policy sought to give all nations equal access to the profitable trade in China. Since the 1890's, a secret Chinese society known as the *Boxers* had opposed Western and Japanese influence in China. In 1900, the Boxers began an uprising called the Boxer Rebellion to drive out the foreigners. McKinley sent 5,000 U.S. troops to help Germany, Japan, Russia, and other nations crush the rebellion and rescue Europeans and Americans held in Beijing. By thus using his authority as commander in chief, McKinley helped strengthen the presidency. See **Boxer Rebellion; Open-Door Policy.**

Life in the White House remained simple during McKinley's two Administrations. Because of her illness, Mrs. McKinley was not socially active. Her relatives and the President's nieces often served as official hostesses. The President reserved a room to greet his many visitors. Mrs. McKinley usually sat beside the President as he stood in a receiving line.

"President of the whole people." In 1900, the Republicans again nominated McKinley for President. They selected Theodore Roosevelt, a hero of the Spanish-American War and governor of New York, to run for Vice President. Bryan again became the Democratic candidate. His running mate, Adlai E. Stevenson, was Vice President under Grover Cleveland from 1893 to 1897.

During the presidential campaign, Bryan attacked McKinley on the issues of imperialism, free silver, and the growth of big business and illegal monopolies called *trusts.* But the major campaign issue became prosperity. McKinley said, "We have prosperity at home and prestige abroad." McKinley and Roosevelt won a sweeping victory. Afterward, McKinley said: "I can no longer be called the President of a party; I am now the President of the whole people."

McKinley's second Administration (1901)

During McKinley's short second term, the United States extended the policies that he had already established. In March 1901, it enacted the Platt Amendment, which later became part of Cuba's Constitution. This amendment gave the United States the right to intervene if Cuba's affairs became unsettled. In May, the Supreme Court of the United States decided the Insular Cases, which found that the United States could control territories without granting their people citizenship. In July, McKinley set up a civilian government in the Philippines.

Revised policies. By 1901, McKinley no longer fully supported the growth of big business. He told aides that government would have to address the problem of industrial consolidation, in which companies in the same industry combined to form a single company. Business owners in the United States had formed huge trusts and other monopolies that hurt competition and kept prices high for consumers.

Also by 1901, McKinley had modified his views on tariffs. He no longer supported protective tariffs to help businesses. Instead, he favored freer commerce through *reciprocal trade agreements,* arrangements with other countries to reduce tariffs on each other's exports. McKinley introduced this policy at the Pan American Exposition in Buffalo, New York, on Sept. 5, 1901. He said, "By sensible trade relations which will not interrupt our home production, we shall extend the outlets for our increasing surplus" of products. He concluded, "The period of exclusiveness is past."

Assassination. On September 6, the day after McKinley's trade speech, the President held a reception in the exhibition's Temple of Music. Among the crowd of people attending was Leon F. Czolgosz, an *anarchist* (person who opposes regulations and government). A handkerchief covered a revolver that Czolgosz carried in his right hand. When McKinley approached him to shake hands, Czolgosz fired two bullets at the President. One bullet ricocheted off McKinley's button, but the other

pierced the President's stomach. McKinley was rushed to a hospital for surgery. He lived for eight days before gangrene and infection overwhelmed him. McKinley died the morning of Sept. 14, 1901, just over six months after beginning his second term as President. Czolgosz was later convicted of murder and electrocuted.

Roosevelt rushed from a vacation in the Adirondack Mountains when he learned McKinley was near death. But by the time Roosevelt reached Buffalo on September 14, McKinley had died. Roosevelt took the oath of office that same day and became President. Mrs. McKinley died in 1907 in Canton. She and her husband are buried there at the McKinley National Memorial.

D. "President of the whole people"

IV. **McKinley's second Administration (1901)**
A. Revised policies
B. Assassination

Questions

What was McKinley's relationship to: Mark Hanna? William Jennings Bryan? Theodore Roosevelt?
How did McKinley begin his political career in Ohio?
How did the United States change its position in world affairs during McKinley's Administrations?
What policy was McKinley famous for supporting when he was in Congress?
How did McKinley strengthen the presidency during his terms?
What was McKinley's policy toward Spain and Cuba in 1897?
What were two improvements McKinley made as governor of Ohio?
What stand did McKinley take on free silver during the 1896 campaign? Why?
Who shot McKinley? Where and when did it occur?
What two policies did McKinley no longer fully support in his second Administration?

McKissick, Floyd Bixler (1922-1991), was an African American civil rights leader. He became known for his efforts to help blacks gain political and economic control over their communities.

McKissick was born in Asheville, North Carolina. He received a law degree from North Carolina College (now North Carolina Central University) in 1951. Later, as a lawyer, he won lawsuits that allowed his children to enter previously all-white schools.

In 1960, McKissick became legal counsel for the Congress of Racial Equality (CORE), a civil rights organization. He was its national chairman from 1963 to 1966 and its national director from 1966 to 1968.

After leaving CORE, McKissick worked to help African Americans obtain positions of power in cities where they made up a large part of the population. He also formed a company to promote black business projects.

In 1974, McKissick's company began building Soul City, a new town near Henderson, North Carolina. He withdrew from the project in 1980 and returned to law. In 1990, he was appointed judge in the Ninth Judicial District in North Carolina. Alton Hornsby, Jr.

McKuen, *muh KYOON,* **Rod** (1933-), is a popular American poet and composer. Most of his poems and songs describe loneliness or love. McKuen often has performed his works in concerts and on recordings.

McKuen's most popular books of poetry include *Stanyan Street and Other Sorrows* (1966), *Lonesome*

Cities (1968), and *In Someone's Shadow* (1969). He has composed more than 1,000 songs. Many of his lyrics were published in *Listen to the Warm* (1967). McKuen also has written classical music and music for motion pictures. His book *Finding My Father* (1976) tells about his search for his father, who deserted McKuen's family.

Rod Marvin McKuen was born in Oakland, California. He ran away from home when he was 11. For several years, he did odd jobs. His first book of poems was *And Autumn Came* (1954). John S. Wilson

McLachlin, Beverley Marian (1943-), became the first woman chief justice of the Supreme Court of Canada in 2000. She has served on the Supreme Court since 1989, when she was appointed by Prime Minister Brian Mulroney. On the court, McLachlin has gained a reputation as an independent, and she has written numerous dissenting opinions.

McLachlin was born Beverley Gietz in Pincher Creek, Alberta. During the 1960's, she attended the University of Alberta, where she earned bachelor's and master's degrees in philosophy and a law degree. In 1967, she married Roderick McLachlin, a fellow student. After her graduation, Beverley McLachlin practiced law in private firms. From 1974 to 1981, she taught law at the University of British Columbia. In April 1981, she was appointed to the County Court of Vancouver. In September, she was elevated to the British Columbia Supreme Court. She was appointed to the province's Court of Appeal in 1985. In 1988, she became the first female chief justice of the British Columbia Supreme Court. Andrew D. Heard

McLaughlin, *muhk LAHK lihn,* **Audrey Marlene** (1936-), served as leader of Canada's New Democratic Party (NDP) from 1989 to 1995. She was the first woman to head an important national political party in Canada. McLaughlin succeeded Edward Broadbent as the party's leader. She became known as a moderate social democrat and supported a mixture of public and private enterprise in the Canadian economy.

McLaughlin was born in Dutton, Ontario. She earned a Bachelor of Arts degree from the University of Western Ontario in 1964. In 1970, she received a Master of Social Work degree from the University of Toronto and became a social worker. She moved to the Yukon Territory in 1979. From 1987 to 1997, she represented the Yukon in the House of Commons. Kendal Windeyer

McLoughlin, *muhk LAWF lihn,* **John** (1784-1857), a Canadian-born trader, is sometimes called the *father of Oregon.* He played a leading part in settling the Oregon Territory. He became a partner in the North West Company, a fur-trading company, in 1814 and took charge of Fort William in 1815. After the North West and Hudson's Bay companies merged in 1821, he ran their business in the Oregon country from 1824 to 1846. He developed trading posts and friendly relations with Indians, whose cultures he found interesting. He had to resign for helping new settlers at his company's expense.

McLoughlin was born at La Rivière du Loup, Quebec. Oregon placed his statue in the United States Capitol in 1953. Dan L. Flores

McLuhan, *muhk LOO ihn,* **Marshall** (1911-1980), was a Canadian professor and writer whose theories on mass communication have caused widespread debate. According to McLuhan, electronic communication—especially television—dominates the life of all Western peoples. It affects their ways of thinking as well as their institutions. McLuhan analyzed the effects of communications media on people and society in *The Mechanical Bride* (1951), *The Gutenberg Galaxy* (1962), *Understanding Media* (1964), *The Medium Is the Massage* (1967), and *War and Peace in the Global Village* (1968).

McLuhan argued that each major period in history takes its character from the medium of communication used most widely at the time. For example, he called the period from 1700 to the mid-1900's the *age of print.* At that time, printing was the chief means by which people gained and shared knowledge. McLuhan claimed that printing encouraged individualism, nationalism, democracy, the desire for privacy, specialization in work, and the separation of work and leisure.

According to McLuhan, the electronic age has replaced the age of print. Electronics speeds communication so greatly that people in all parts of the world become deeply involved in the lives of everyone else. As a result, said McLuhan, electronics leads to the end of individualism and nationalism and to the growth of new international communities.

Interest in McLuhan's work resurfaced in the 1980's. He is among the first of the *postmodernist writers,* who believe that our society has become driven by computers and electronics. They argue that electronics has revolutionized work, politics, culture, and art.

McLuhan was born in Edmonton. His full name was Herbert Marshall McLuhan. James W. Carey

M'Clure, Sir Robert John Le Mesurier. See McClure, Sir Robert John Le Mesurier.

McMurtry, Larry (1936-), is an American novelist whose fiction reflects his Southwestern heritage. McMurtry writes about dissatisfied, lonely characters living in dying Western towns. His novels move beyond traditional Western fiction through their use of black humor, their frank treatment of sex, and their theme of the rootless Texan lost in the big city. McMurtry contrasts dreams of grandeur with the harsh realities and limited options open on the contemporary frontier. There is a mournful tone to much of his fiction, in response to the fading away of traditions of simplicity and freedom usually associated with the West.

Larry Jeff McMurtry was born in Wichita Falls, Texas. His early novels, such as *Horseman, Pass By* (1961) and *The Last Picture Show* (1966), reflect cheerless life on the ranches and in the small towns of west Texas. *Terms of Endearment* (1975) and McMurtry's other novels of the 1970's explore Texas characters who have been attracted to the urban environment. His major work is a series of four novels set in the Texas frontier of the 1800's. They are, in the order of the events they describe, *Dead Man's Walk* (1995), *Comanche Moon* (1997), *Lonesome Dove* (1985), and *Streets of Laredo* (1993). *Lonesome Dove,* which describes a cattle drive of the 1800's, won the 1986 Pulitzer Prize for fiction. *Buffalo Girls* (1990) uses historical figures from Western history to portray the passing of the Wild West era. *The Evening Star* (1992) is a sequel to *Terms of Endearment. Texasville* (1987) and *Duane's Depressed* (1999) are sequels to *The Last Picture Show.* McMurtry also wrote the nonfiction work *Walter Benjamin at the Dairy Queen* (1999). Arthur M. Saltzman

McNally, Terrence (1939-), is an American playwright who writes in a variety of styles. McNally's works

include light comedies, satires, the scripts for musicals, and serious dramas about people trying to deal with the insecurities of life.

McNally first gained recognition with several short comic plays in the late 1960's. His first successful full-length play was the farce *The Ritz* (1975), about a man trapped in a Turkish bath filled with strange characters. The more serious *Frankie and Johnny in the Clair de Lune* (1988) portrays a woman who believes she is unattractive and cannot believe that a man loves her. In *The Lisbon Traviata* (1979), opera fans use their hobby as a way of avoiding real life. *Love! Valour! Compassion!* (1994) shows a group of gay men coping with life during the AIDS epidemic. *Master Class* (1994) imagines opera singer Maria Callas near the end of her career.

McNally's other plays include *It's Only a Play* (1982), *Lips Together, Teeth Apart* (1991), and *A Perfect Ganesh* (1993). He also wrote the scripts for the musicals *The Rink* (1984) and *Kiss of the Spider Woman* (1990). He was born on Nov. 3, 1939, in St. Petersburg, Florida.

Gerald M. Berkowitz

McNamara, Robert Strange (1916-), was United States secretary of defense from 1961 to 1968. He served under Presidents John F. Kennedy and Lyndon B. Johnson. As secretary, he became an important adviser to the presidents in economic and foreign affairs as well as in military matters. American military involvement in the Vietnam War became a major U.S. foreign policy issue in the 1960's. McNamara promoted increasing the involvement. Years later, in 1995, he said he and other government officials had been wrong in getting the United States deeply involved in the Vietnam War. He dealt with the issue in his book *In Retrospect: The Tragedy and Lessons of Vietnam* (1995).

McNamara was born on June 9, 1916, in San Francisco. He graduated from the University of California and the Harvard Business School, and taught at Harvard from 1940 to 1943. In 1946, after serving in the U.S. Army Air Forces in World War II, he became a Ford Motor Company executive. He was named president of Ford in November 1960, shortly before he became secretary of defense. From 1968 to 1981, after his government career, he was president of the World Bank. James I. Lengle

McNary, *muhk NAIR ih,* **Charles Linza,** *charlz LIHN zuh* (1874-1944), served as a United States senator from Oregon from 1917 until his death. He was the Republican candidate for vice president in 1940. He and presidential candidate Wendell L. Willkie lost to President Franklin D. Roosevelt and Henry A. Wallace. A liberal Republican, McNary supported federal aid to farmers during the 1920's and many New Deal programs in the 1930's (see **New Deal**). He served as Senate minority leader from 1932 until his death. Born near Salem, Oregon, on June 12, 1874, he attended Stanford University.

David E. Kyvig

McNaughton, *muhk NAW tuhn,* **Andrew George Latta,** *AN droo jawrj LAT uh* (1887-1966), was a noted Canadian soldier of World Wars I and II. He took command of the First Canadian Division at the outbreak of World War II in 1939. He commanded the Canadian Corps from 1940 to 1942 and the Canadian Army in 1942 and 1943. In 1944, he served as defense minister under Prime Minister Mackenzie King. He served as chairman of the Canadian sections of the Canada-United States Permanent Joint Board on Defense from 1945 to 1962 and of the International Joint Commission from 1950 to 1962 (see **International Joint Commission**).

McNaughton was a gunnery officer in World War I (1914-1918) and became a brigadier general in 1918. He was credited with developing techniques for locating enemy artillery so that it could be disabled. He was also the co-inventor of a cathode-ray direction finder used in airplanes. From 1935 to 1939, he served as chairman of the Canadian National Research Council. He was born on Feb. 25, 1887, in Moosomin, Saskatchewan.

Desmond Morton

McPherson, *muhk FUR suhn,* **Aimee Semple** (1890-1944), a colorful American evangelist, founded the International Church of the Foursquare Gospel. McPherson stressed salvation, divine healing, baptism by the Holy Spirit, and the Second Coming of Christ. She worked as a revivalist in the Full Gospel Assembly from 1908 to 1910 and was a missionary in China in 1910 and 1911. She built Angelus Temple in Los Angeles in 1922. McPherson was born on Oct. 9, 1890, in Salford, Ontario. See also **Faith healing**. Henry Warner Bowden

Mead, Lake. See Lake Mead.

Mead, *meed,* **Margaret** (1901-1978), was an American anthropologist known for her studies of how culture influences the development of personality. She lived among peoples of the Pacific Islands to study their ways of life. Mead described how cultures differ in what behavior they consider appropriate. She also studied how children learn to become part of their culture.

Mead's best-known book, *Coming of Age in Samoa* (1928), compares the lives of adolescents in a Samoan village and in Western societies. The accuracy of her comparisons was later challenged, making anthropologists even more aware that such field research may be interpreted in more ways than one. Her other books include *Growing Up in New Guinea* (1930), *Sex and Temperament in Three Primitive Societies* (1935), *Male and Female* (1949), and *Culture and Commitment* (1970).

Mead was born on Dec. 16, 1901, in Philadelphia. She graduated from Barnard College and received a Ph.D. degree in anthropology from Columbia University. From 1926 to 1969, she was a curator of ethnology at the American Museum of Natural History in New York City.

Judith Modell

Additional resources

Lapsley, Hilary. *Margaret Mead and Ruth Benedict.* Univ. of Mass. Pr., 1999.
Mark, Joan. *Margaret Mead.* Oxford, 1999.

Meade, *meed,* **George Gordon** (1815-1872), was a Union general in the American Civil War (1861-1865). He led the victorious Union Army at the Battle of Gettysburg in July 1863 (see **Gettysburg, Battle of**).

When the Civil War began, Meade became a brigadier general of volunteers from Pennsylvania. Beginning in 1862, he fought in most of the important battles in the East, including the peninsular campaign, the Second Battle of Bull Run (also called Manassas), and the battles of Antietam (also called Sharpsburg), Fredericksburg, and Chancellorsville. He became a major general of volunteers after Antietam and a corps commander after Fredericksburg. In June 1863, he replaced General

Joseph Hooker as commander of the Army of the Potomac. Three days later, Meade showed his skill and military judgment in defeating the Confederates at Gettysburg. Jealous subordinates and Republican politicians criticized his battlefield leadership and blamed him for the Confederate Army's escape into Virginia. But he kept his command for the rest of the war, and his major decisions and actions proved to be correct.

Meade was born in Cádiz, Spain, the son of an American naval agent. He was educated in the United States and graduated from the U.S. Military Academy in 1835. He served in the Second Seminole War (1835-1842) and in the Mexican War (1846-1848). After the Civil War, he held various military commands. James E. Sefton

Meadow saffron. See Colchicum.

Meadowlark is the common name of two similar species of North American birds that inhabit grassy fields, meadows, and prairies. The *eastern meadowlark* usually lives in moister habitats than does the *western meadowlark.* The eastern meadowlark is found from southern Ontario south to the Amazon River in South America, and it ranges westward to Arizona. The western meadowlark is found from southern British Columbia to central Mexico, and as far east as Ohio.

WORLD BOOK illustration by Trevor Boyer, Linden Artists Ltd.
Eastern meadowlark

Meadowlarks are not true larks. They belong to the same family as blackbirds and orioles. Meadowlarks are about the size of robins but have a heavier body, shorter tail, and longer bill. The back, wings, and tail of the meadowlark are brownish, streaked with black. The throat and underparts of the bird are bright yellow with a large, black, V-shaped band on the breast. White feathers on each side of the tail are flashed when the meadowlark is nervous or in flight.

The eastern meadowlark's song consists of two clear whistles, the second ending as a slurred, drawn-out note. It is one of spring's first bird songs. The western meadowlark's song has 7 to 10 flutelike, gurgling notes.

The meadowlark builds its nest on the ground, usually with a dome-shaped roof of grass hiding the eggs. Both species lay three to seven white eggs speckled with reddish-brown. Meadowlarks eat some waste grain and vast quantities of weed seeds and harmful insects. Edward H. Burtt, Jr.

Scientific classification. Meadowlarks belong to the subfamily Icterinae of the emberizid family, Emberizidae. The scientific name for the eastern meadowlark is *Sturnella magna.* The western meadowlark is *S. neglecta.*

See also **Bird** (table: State and provincial birds; pictures: Birds of grasslands; Birds' eggs).

Mean, in statistics, is the sum of a series of numbers divided by the number of cases. Suppose five boys weigh 67, 62, 68, 69, and 64 pounds. The sum of their weights is 330 pounds. Divide this sum by 5, the number of boys, or cases: 330 ÷ 5 = 66. The *mean* of this series of numbers is 66, and the *mean weight* of the boys is 66 pounds. This single weight of 66 pounds can be used to represent the differing weights of all five boys, even though none of them weighs exactly 66 pounds. The mean is often called the *arithmetic average* or *arithmetic mean.* See also **Average; Median; Mode; Statistics** (Probability). Doris F. Hertsgaard

Meany, George (1894-1980), served as the first president of the American Federation of Labor and Congress of Industrial Organizations (AFL-CIO). He held the office from 1955, when the AFL and CIO merged, until he retired in 1979. Before the merger, Meany had served as president of the AFL since 1952.

Meany made it one of his chief tasks to eliminate corruption in labor unions. He was influential in expelling the big and powerful Teamsters Union from the AFL-CIO in 1957, after its leaders were accused of unethical practices.

Meany played a major role in the AFL-CIO's international activities. He tried to strengthen anti-Communist forces in labor, and he strongly supported United States policy on the Vietnam War (1957-1975). In 1963, Meany received the Presidential Medal of Freedom.

Meany was highly critical of President Richard M. Nixon's efforts to halt inflation. However, he agreed in 1971 to serve on a Pay Board that Nixon set up to control wage increases. Several months later, Meany resigned from the Pay Board, accusing the Nixon Administration of favoring business over labor.

Meany was born in New York City. He became an apprentice plumber when he was 16 years old. Meany served as president of the New York State Federation of Labor from 1934 to 1939 and as secretary-treasurer of the AFL from 1940 to 1952. Daniel Quinn Mills

See also **Labor movement** (Reunification of the AFL and the CIO; picture).

Measles is a disease that causes a pink rash all over the body. It is extremely contagious. The disease occurs chiefly in children, but some young adults also catch it. Few people in the United States or Canada die of measles. But the disease kills many undernourished children in developing countries. The medical name for measles is *rubeola. German measles,* known medically as *rubella,* is a different disease with similar symptoms (see **Rubella**).

Before the 1960's, most children in the United States caught measles. In 1963—in a major medical advance—a team of virologists led by U.S. researcher John F. Enders developed a measles vaccine. By the early 1980's, the use of this vaccine had practically eliminated measles from the United States. But widespread outbreaks of measles among children and young adults beginning in the late 1980's have caused U.S. health officials to intensify vaccination programs against the disease.

Cause and effects. A virus causes measles. People who have the disease spread the virus by coughing and sneezing. The first symptoms appear about 10 days after the virus enters a person's body. A fever, cough, and runny nose develop, and the eyes become red and watery and sensitive to light. The fever may reach 105 °F (41 °C). Small pink spots with gray-white centers develop inside the mouth, especially on the insides of the cheeks. They are called *Koplik's spots.* A person with symptoms of measles should call a physician.

Three to five days after the first symptoms appear,

faint pink spots break out on the face near the hairline. The rash spreads all over the body within two or three days. About the time it reaches the feet, the patient's fever drops and the runny nose and cough disappear. The patient's rash begins to fade at the same time. Some people who are weakened by measles suffer various complications, including infections of the lungs and the middle ear. The virus can harm the brain, but this is not common.

No drug exists to cure measles after it develops. Patients should be kept comfortable while the disease lasts. In most cases, a person has measles only once. The body produces *antibodies* (substances that fight infection) during the disease. These antibodies normally provide lifelong *immunity* (protection) from later attacks.

Prevention. In 1954, Enders separated the measles virus from other substances and grew it in living cells in test tubes. He later developed a vaccine from the virus. Since 1963, millions of young children have received a single injection of the vaccine to prevent measles. It usually is given when the child is about 15 months old. Most American physicians recommend a second injection for older children or adolescents.

Measles vaccine contains live measles virus that has been weakened by a long period of growth in animal cells in a test tube. When injected into a person's body, this virus produces a mild form of the condition and, in most people, no symptoms appear. But the body reacts to the weakened virus just as it would to an ordinary virus. That is, it produces antibodies that fight the virus and provide immunity to measles. Scientists do not know how long the immunity lasts. In most people, it continues for many years—perhaps for life. In the United States, measles occasionally occurs in adolescents and young adults who have never received the measles vaccine or who have received it only once.

The vaccine cannot stop measles from developing in someone who already has the virus. For a very few children who have been exposed to measles and who are at risk of developing other, more severe disease, doctors may try to prevent measles by using *gamma globulin treatment.* In this treatment, a doctor injects gamma globulin, a part of the blood. The gamma globulin that is used comes from people who have had measles, and so it contains antibodies. Neil R. Blacklow

Measure. See **Music** (Rhythm; Musical notation).

Measurement. See **Weights and measures.**

Measuring worm is a moth caterpillar that moves by looping its body forward. Measuring worms are also called *inchworms, loopers,* or *spanworms.* A measuring worm crawls by pulling the back part of its body toward the front part, forming a hump in the middle. It then reaches forward with its six front legs to "measure" the distance it can reach by straightening its body. It moves in this way because it has only two or three pairs of *prolegs* (leglike structures) on the back part of its body. Most other caterpillars have five pairs of prolegs. A measuring worm can stand upright and motionless on a twig. By doing this, it resembles a branch of the twig and can escape the notice of its enemies.

© Anthony Bannister, N. H. P. A.

The measuring worm crawls by arching its body.

There are thousands of species of measuring worms. Some species, such as the *spring cankerworm* and the *fall cankerworm,* are serious pests of fruit and shade trees (see **Cankerworm**). Other species, including the *cabbage looper* and the *omnivorous looper,* damage crops. Measuring worms usually form loose cocoons to enter the pupa stage. The moths that later appear are medium-sized with broad wings that have delicate lined patterns. Charles V. Covell, Jr.

Scientific classification. Most measuring worms belong to the family Geometridae. Others are in the family Noctuidae.

Meat is animal flesh that is eaten as food. Meat consists largely of muscles, but fat and other animal tissue are also considered meat. Many commonly eaten meats come from animals that are raised for food. These animals—and the meats that come from them—are cattle (beef and veal), hogs (pork), sheep (lamb and mutton), and poultry (chicken, duck, and turkey). *Game,* which is meat from wild animals, is also frequently eaten. In addition, fish is included among meat-producing animals. This article discusses meat from cattle, hogs, and sheep, all called *red meat.* For information on poultry and fish, see **Fishing industry; Poultry; Seafood.**

Food value of meat. Most nutritionists consider meat an important part of a well-balanced diet. Meat supplies vitamins, minerals, and fat necessary for good health and growth. Meat also provides an especially good source of proteins, which the body needs to build and maintain its cells and tissues. Proteins are made up of chemical units called *amino acids.* The proteins in meat are called complete proteins because they provide all the essential amino acids—and in the proportions the body requires. See **Amino acid.**

Red meat is an excellent source of the vitamin B complex group. Thiamine (B_1) is especially abundant in pork. Thiamine helps maintain the circulatory and nervous systems and aids the body in storing and releasing energy. Riboflavin (B_2) is needed for normal growth and healthy skin. Pyridoxine (B_6) helps prevent nervous disorders and skin diseases. Vitamin B_{12} found naturally only in meat, helps maintain red blood cells. Niacin is important in preventing a disease called pellagra (see **Pellagra**). Liver, an especially nutritious meat, also provides vitamins A and C. The body needs these vitamins for normal vision and healthy gums and tissue.

Meat is rich in iron, which is needed to build and maintain red blood cells and muscle growth. Meat is also a good source of copper, phosphorus, and zinc. The fat in meat is an excellent source of energy and certain fatty acids the body cannot produce itself. However, about half of the fatty acids in meat fat are *saturated.* Saturated fats help form a fatty substance called *cholesterol.* Large amounts of cholesterol in the body significantly increase the risk of heart disease. Small children

need fat in their diets for proper development of the brain and nervous system. Nutritionists advise that adults eat only moderate amounts of fats, regardless of whether the fats are saturated or unsaturated.

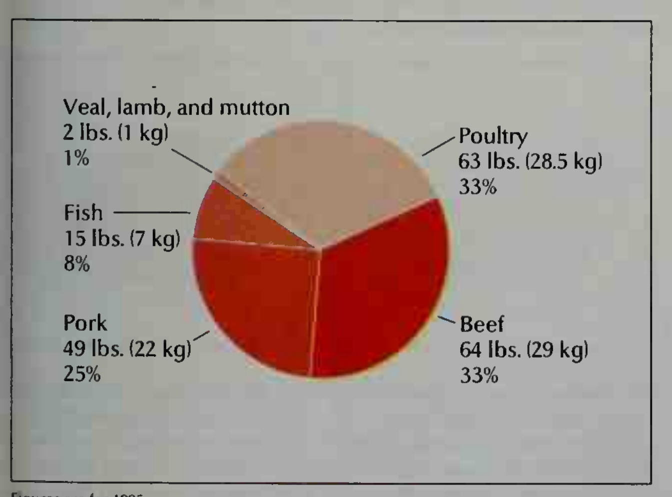
Kinds of meat. There are several different types of red meat. The names for meat from cattle and sheep tell the age of the animal from which the meat was taken.

Veal is the flesh of calves less than 14 weeks old. It is light pink and contains little fat. Veal is more tender than beef and has a milder flavor. Meat from calves over 14 weeks old is called *calf.*

Beef is the flesh of full-grown cattle. Most beef sold at stores comes from animals 1 to 2 years old. Beef is bright red and has white fat. Flecks of fat called *marbling* help make beef tasty and juicy.

Lamb is the flesh of sheep less than 1 year old. It is red and has white fat. Lamb has a milder taste than mutton.

Mutton is the flesh of sheep over 1 year old. It has a deep red to purple color. Mutton has a stronger flavor and a coarser texture than lamb.



Pork is the flesh of hogs. Most pork comes from animals from 4 to 7 months old. Pork has a light pink color, with white fat. It has a mild taste. Many cured meats, such as ham, bacon, and sausage, are made from pork.

Variety meat is the general name for various organs and glands of meat animals. Common variety meats include the brains, hearts, kidneys, livers, and tongues of animals. Some other variety meats are *chitterlings* (hog large intestines), *sweetbreads* (pancreas and thymus glands), and *tripe* (linings of first and second cattle stomachs). Most variety meats are good sources of vitamins and minerals.

Meat is available in fresh, frozen, canned, and cured forms. Fresh meat is raw meat. Fresh meat spoils quickly and must be refrigerated until it is cooked. People can keep fresh meat from spoiling by freezing it. Frozen meat is also sold in stores. It has the same food value as fresh meat and is often used by restaurants. Frozen meat should be cooked as soon as it thaws and should not be refrozen.

Average consumption of various meats

This graph shows the average amounts of various kinds of meat consumed per person in the United States in a year. The amounts are for boneless, trimmed weight, which represents the edible weight of the meat.

Figures are for 1995.
Source: U.S. Department of Agriculture.

Meat may be packaged in a variety of ways. Vacuum packing is the best method because the process removes air from the package and thus prevents the growth of many types of bacteria. Retail stores often wrap meat in clear plastic film. Such plastic film is designed for storage in a refrigerator but will not protect meat from drying out in a freezer.

Canned meat has been sealed in a metal can and then heated. The heat cooks the meat and destroys bacteria. Meat is often canned with other ingredients, such as vegetables or gravy. Cured meat, such as ham, bacon, and sausage, has been treated with salt and sodium nitrite to control bacterial growth.

How to select meat. In the United States, all meat sold in stores is inspected by the U.S. Department of Agriculture (USDA) or by a state inspection service. Meat sold in stores is often graded according to its quality. Meat may be graded on a system used by the USDA, or individual stores may do their own grading. Higher grades of meat are more tender, juicy, and flavorful than lower grades. The grade of a meat is stamped directly on the meat in purple vegetable dye or on the package label.

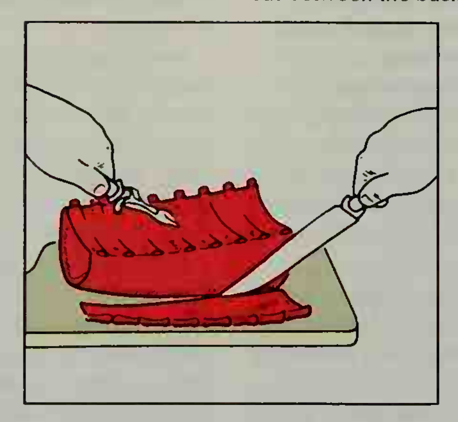
The USDA grades for beef are prime, choice, select, standard, commercial, utility, cutter, and canner. Prime, the highest and most expensive grade of beef, is mainly sold to restaurants but can sometimes be bought in stores. Choice and select meats are commonly sold in stores. The lower grades of beef are usually used to make processed meat products, such as bologna. Veal and lamb are graded on similar systems ranging from prime (the highest grade) to cull (the lowest). Pork is often not graded because the meat is uniform in quality.

Grading is based on such quality factors as age, marbling, fat, firmness and texture, and color of the meat. Because marbling makes meat more tasty and juicy, good meats will contain more marbling than poor meats. White to creamy-white firm fat is preferable to yellow fat, and a fine texture is better than a coarse one.

How meat is cooked. There are two main ways to cook meat: (1) with dry heat and (2) with moist heat. The method is determined by a meat's cut and tenderness.

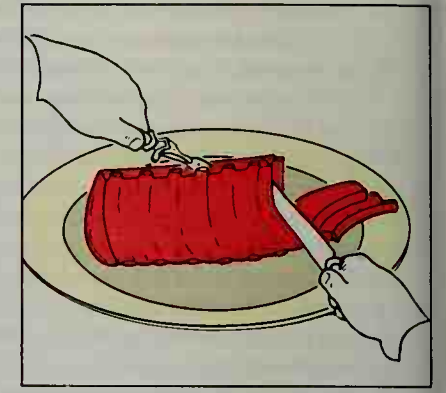
Dry heat methods include broiling, panbroiling, roasting, panfrying, and deep-fat frying. These methods are best for tender cuts of meat. Broiled (grilled) meat is cooked directly above or below a source of heat. Meat may be broiled on a grill over hot coals or under the heating element of an open oven. In panbroiling, meat is cooked in a pan or griddle over low heat. In roasting (baking), meat is cooked in a shallow pan in an oven. It is best to raise the meat on a rack in the pan so the heat can circulate around the meat. In panfrying, or sautéing, meat is cooked in a small amount of fat over low heat. In deep-fat frying, meat is covered by hot fat.

Moist heat methods, such as braising and cooking in liquid, are best for less tender meats. Moist heat tenderizes meat by softening its connective tissues. In braising, meat is placed in a tightly covered pan at a low temperature. The meat cooks in its own juices or in other liquids that may be added. Simmering and stewing are two ways to cook meat in liquid. Meat is simmered just



How to carve meat

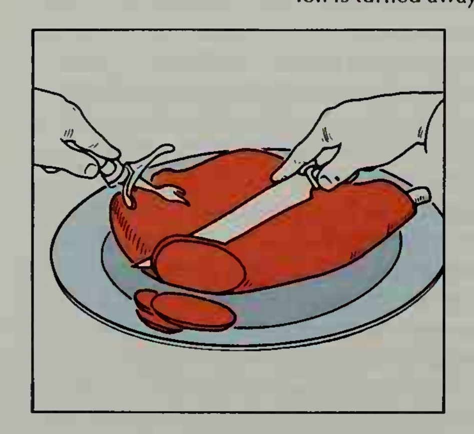
Carving will be easier if you remember a few helpful hints. Allow a large roast to stand for about 30 minutes after it has been taken out of the oven. This will make it easier to cut. Carve across the grain of the meat to prevent stringy slices. To carve neat slices, keep the knife at the same angle while cutting each slice. The directions given on this page and the following page are for right-handed carvers. Left-handed carvers should substitute *left* for *right* and *right* for *left* in the instructions.



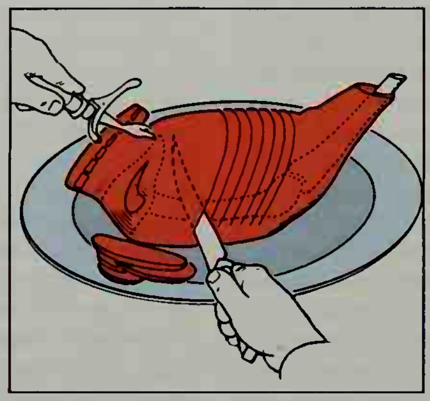
Diagrams prepared through the cooperation of the National Live Stock and Meat Board

Pork loin roast

A pork loin roast is easier to carve if you have a butcher cut between the backbone and the ends of the ribs.

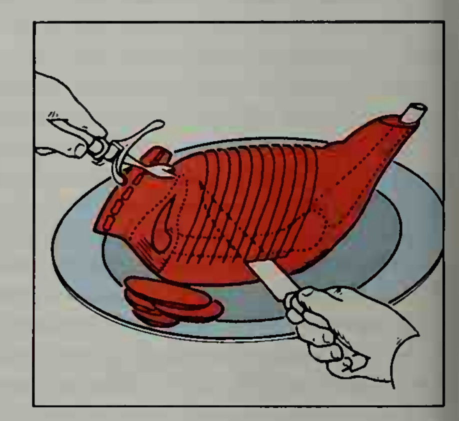


Remove the backbone before slicing the meat. Use the ribs as a guide to cut off the backbone. If a butcher has already separated the backbone from the ribs, it will be loose and easy to remove.



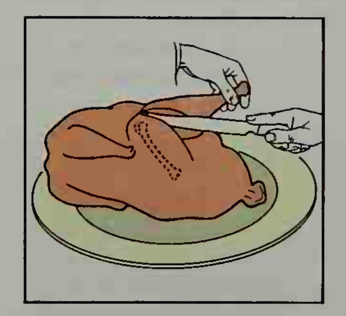
Slice the meat with the fork inserted firmly in the top of the roast. Cut close to each rib. The size of the loin will determine how many boneless slices you can cut between the ribs.

Roast leg of lamb

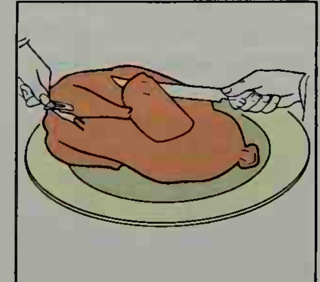


The thick, meaty section of a roast leg of lamb is called the *cushion* of the leg. When carving begins, as shown in the first diagram below, the leg should be placed on the platter so that the cushion is turned away from the carver.

Place the shankbone to your right, keeping the cushion away from you. Insert the fork firmly and carve two or three slices from the thin side of the roast opposite the cushion.

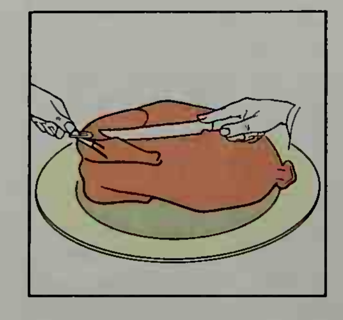


Turn the roast up, so it rests on the surface just cut. Insert the fork at the left of the roast. Starting at the shank end, opposite your fork, make parallel slices down to the bone.

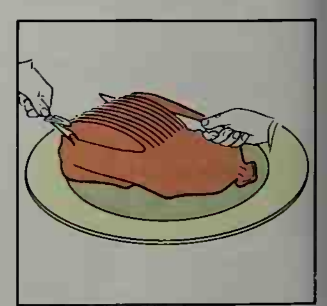


Release all the slices at the same time by running the knife along the leg bone at the bottom of the parallel cuts. The slices can then be lifted off the bone and placed on a platter for serving.

Roast turkey

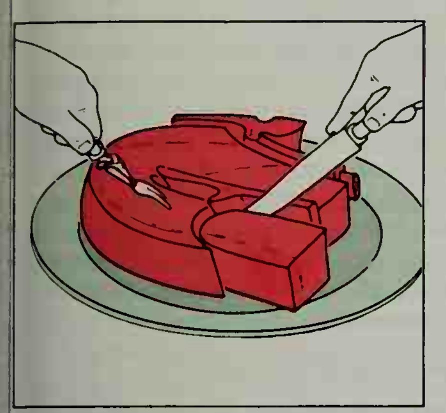


A roast turkey has both dark meat and white meat. The dark meat comes from the turkey's legs (drumsticks) and thighs. The white meat comes from the turkey's wings and breast. Roast turkey is a popular main course of many holiday meals, and is often carved at the table.

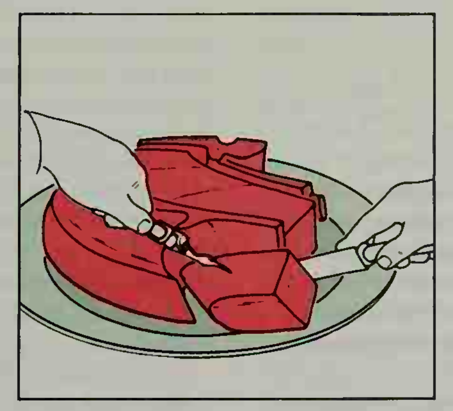


Remove the drumstick by turning the turkey on its side with its breastbone away from you. Pull the end of the drumstick away from you as you cut through the joint.

Carve the thigh next, cutting slices until the bone is exposed. Remove the thighbone by prying it loose with the tip of the knife. Then finish slicing the thigh meat.

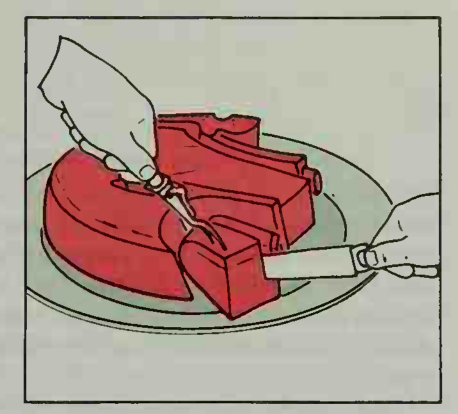


For large slices, carve the breast with the grain. Slice until you reach the wing joint. Remove the wing and then slice all the white meat from one side of the breast.



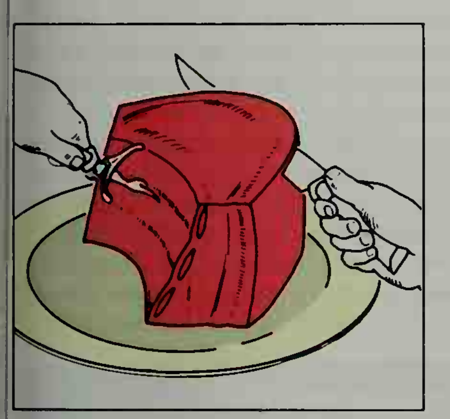
For small slices, carve the breast across the grain. Remove the wing and then cut slices reaching down to the keel bone. Cut across the bone to release the slices.

Blade pot roast

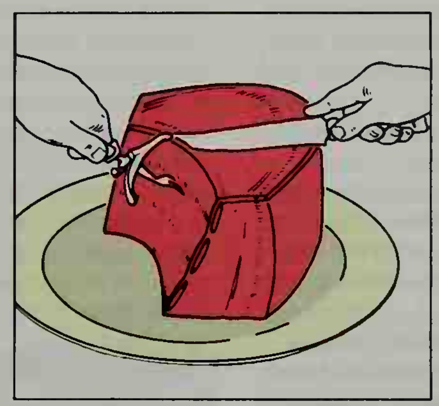


A blade pot roast contains part of the bladebone and part of a rib. The tissue around the bones softens as the meat is cooked, making it easy to remove the bones when the pot roast is carved.

Hold the roast firmly in place with the fork inserted in the top of the meat. Separate a section of the roast by running the knife between two muscles and along the bone, as shown.

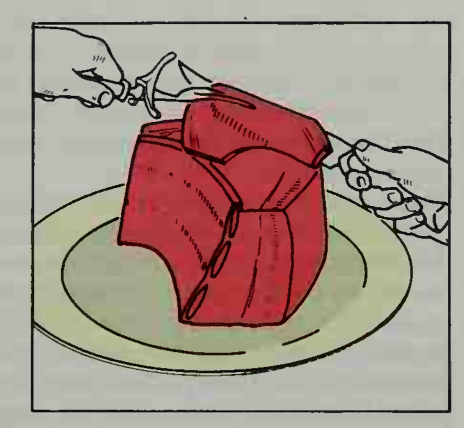


Turn the section just separated from the roast so that you can cut across the grain of the meat. Insert the fork firmly in the top of the section to hold the meat in place while it is sliced.



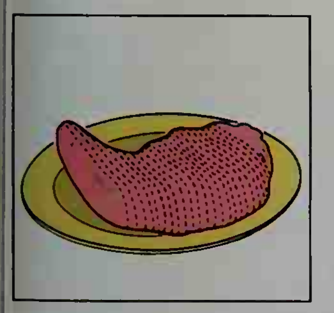
Carve the section by cutting thin slices across the grain. Cut and slice the other sections of the pot roast in the same manner. Remove the bones from the platter before serving.

Standing rib roast

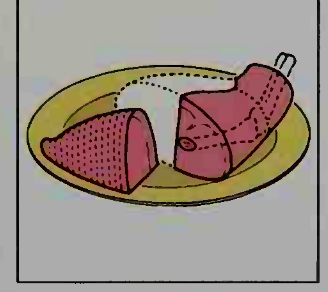


A standing rib roast has at least two and sometimes three ribs. The meat may be cut into thick or thin slices. When carving this large cut of meat, it is helpful to have a second platter nearby to hold the slices of meat you cut from the roast.

Place the roast on the platter so the small cut surface is up and the ribs are to your left. Insert the fork between the top two ribs. Starting from the outside edge, slice across the grain to the ribs.

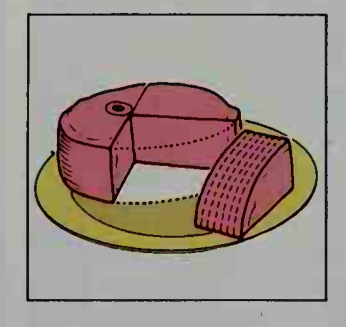


Release each slice as it is cut by running the tip of the knife along the edge of the rib. After a slice has been released, remove it from the roast so the next slice can be cut.

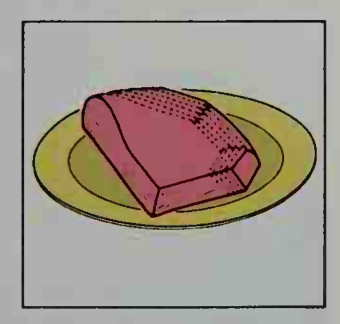


Remove each slice by lifting it off the roast with the blade of the knife. Slide the knife under the slice and hold the meat in place with the fork. Then place the slice on a platter for serving.

Other cuts of meat



Many other cuts of meat are popular foods in the United States. Such cuts include beef tongue, half ham, center-cut ham slice, and beef brisket. These cuts are shown in the diagrams below, along with instructions for carving them.



Beef tongue should be carved from the larger to the smaller end in thin, parallel slices. The larger end may have excess tissue that should be trimmed from the meat.

Half ham has a cushion section that can be easily removed and sliced. Separate the other section from the shank and remove the bone. Then slice the boned section.

Center-cut ham slice should be cut into three pieces before it is sliced. Slice each piece across the grain of the meat. Remove the bone before slicing the end piece.

Beef brisket often has excess fat that should be removed before carving. Position the rounded side of the brisket away from you and cut slices from it in rotation as shown.

below the boiling point. In stewing, the meat is slowly boiled in a covered pot or pan. C. Lynn Knipe

Cooking	Food	Meat packing

Meat extract is a paste with a highly concentrated meaty flavor. Cooks often flavor soups and sauces with meat extract. Food manufacturers use beef extract or chicken extract in making bouillon cubes. When dissolved in hot liquid, these cubes produce a fragrant broth.

Food manufacturers make meat extract by boiling fresh, lean meat in a vacuum kettle. They boil the meat until it loses nearly all its color and the water turns brown. Then they remove the meat and boil the juice again until most of the liquid has evaporated. As the remaining extract cools, it forms a paste. Meat extract has a yellowish-brown color, and a pleasant, meaty odor and flavor.

Meat extract has little food value, though it does contain some protein and minerals. The meat left after boiling, even though flavorless, usually contains more food value than the extract. To add to the extract's food value, sometimes the boiled meat is ground or powdered and put back in the broth. Donald H. Beermann

Meat Inspection Act. See **Roosevelt, Theodore** (Domestic problems).

Meat packing is the business of slaughtering cattle, hogs, and sheep, and preparing the meat for transportation and sale. The term *meat packing* comes from the once-common practice of packing highly salted meat in wooden barrels. The American colonists used this technique to preserve meat for storage or for shipment overseas. Today, meat packers use refrigeration as well as smoking, curing, and canning to preserve meat.

Oscar Mayer Foods Corporation

Meat cutters use special knives to carve portions of livestock carcasses into smaller wholesale or retail cuts.

Meat packing is a major industry in many countries. China produces the most *red meat* (meat of cattle, hogs, and sheep). Other leading producers of red meat include Brazil, France, Germany, and the United States.

In the United States alone, the meat-packing industry produces more than 39 billion pounds (17.7 billion kilograms) of meat annually. About 140 million farm animals must be slaughtered yearly to produce this amount of meat. Raising and slaughtering these animals and processing the meat provide jobs for thousands of farmers, ranchers, butchers, and meat packers. About 5,000 meat-packing and processing plants in the United States employ about 225,000 workers.

Marketing of livestock

Kinds of markets. Each weekday, farmers and ranchers in the United States sell about 500,000 meat animals. More than two-thirds of the cattle, hogs, and sheep are sold directly to meat packers, a practice called *direct marketing.* Some livestock owners sell their animals through large trading centers called *terminal markets.* There are about 50 terminal markets in the United States. Stockyards at these markets provide pens, weight scales, and other facilities for handling and selling large numbers of livestock. Farmers and ranchers also sell animals through smaller markets called *auction markets* or *sale barns,* which operate throughout the farming areas of the United States. Animals are shipped to packers or to market by train or truck.

Many meat packers operate slaughterhouses in terminal-market cities. But not all animals shipped to terminal markets are sold and processed in those areas. Some are shipped on to other markets and then sold. Others are bought and shipped on to meat-packing plants in other cities. The nation's largest terminal markets include those in Sioux Falls, South Dakota; and South St. Paul, Minnesota.

Selling livestock. In the direct-marketing process, livestock owners obtain bids from meat packers. The owners get bids by telephone or from a packing company buyer who visits their feedlot or farm. To make sure that the price is satisfactory, owners may listen to market reports on the radio or get price quotations from other meat packers. After a price has been agreed upon, the animals are shipped to the packer's slaughterhouse.

At terminal markets, livestock owners usually sell their animals through a *commission firm.* This firm acts as an agent for the owner. It sells the livestock to a meat packer or other buyer at the highest possible price. The commission firm receives a commission from the livestock owner for this service. The stockyard also charges the owner for the feed and facilities used by the animals.

Livestock buyers determine a price per 100 pounds (45 kilograms), on the basis of live weight. Factors such as age, sex, weight, grade of the animal, and degree of fatness help buyers determine the price they pay. Expert livestock buyers can accurately estimate the meat yield of a live animal. Their estimate seldom varies more than 1 percent from the actual meat yield after slaughtering and *dressing* (preparing meat for sale).

Packing processes

Meat goes through more than 25 operations before it hangs dressed in packing-house coolers. Skilled work-

ers perform these operations with great speed. Many packing plants slaughter and dress as many as 150 head of cattle or 600 to 1,200 hogs in an hour.

Slaughtering and dressing. Workers use mechanical stunners to make the cattle unconscious, after which the animals are killed and dressed. The carcasses are suspended from an overhead rail for the dressing operation, in which the hide and *viscera* (internal organs) are removed. Workers cut the dressed carcasses into halves, wash them, and move them along the rail to refrigerated rooms. There the carcasses chill to about 35 °F (2 °C) for 12 to 24 hours. Then workers may cut the halves into forequarters and hindquarters.

At wholesale or retail establishments, butchers divide the hindquarter cuts into flank, short loin, sirloin, and round. These cuts make up about half of a dressed beef carcass. The forequarter cuts, the other half, are divided into brisket, chuck, foreshank, rib, and short plate. A choice grade steer that weighs 1,000 pounds (450 kilograms) when alive will yield a carcass of about 600 pounds (270 kilograms).

Calves and lambs are made unconscious by an electric shock. Then workers slaughter and dress them in much the same way as cattle. Packers ship most calves and lambs to wholesalers and retailers as whole carcasses.

Hogs are made unconscious by electricity or gas before they are killed. The carcasses are then scalded and dehaired. The viscera are removed and the carcasses are washed before being cooled overnight in a hog-chill cooler at a temperature of about 35 °F (2 °C). The next day, butchers cut the carcasses into wholesale cuts—hams, shoulders, loins, bellies, spareribs, and other cuts. The cuts are then sent to the shipping room, where they are graded by weight, boxed, and marked for shipment to markets or for further processing.

Oscar Mayer Foods Corporation

A frankfurter machine stuffs meat into long tubes and shapes the tubes into links at a rate of 36,000 links per hour.

Lard makes up about 10 per cent of the weight of a dressed hog. Grinding and heating operations *render* (separate) the lard from the protein in the raw fat. The fat around the kidneys may be made into leaf lard, the best grade.

Curing and smoking processes were once used primarily to preserve meat. Today, meat is preserved mainly by refrigeration, though curing and smoking are still important for long-term preservation. Curing and smoking also produce the special flavor of bacon, ham, and other cuts.

Packers cure most meat by pumping a curing solution into the arteries of the meat, or by injecting the solution directly into the meat. The curing solution is made up largely of salt and water, but sugar may be included. Other ingredients, such as sodium nitrate and sodium ascorbate, are usually added to help develop the cherry-red color of cured meat and to preserve the flavor.

Smoking produces the distinctive smoked-meat flavor which consumers demand in certain meats. Modern smokehouses consist of air-conditioned, stainless-steel rooms. Controlled amounts of smoke from special hardwood sawdust are drawn into the rooms. The warm, fragrant smoke gives the meat a unique flavor and color.

Tenderizing. Consumers want tenderness, as well as flavor, in the meat they buy. Less-tender cuts of meat may be ground to tenderize them. For example, ground beef makes up about 30 per cent of all fresh beef consumed in the United States.

In recent years, chemical tenderizers that are enzymes taken from fruits such as pineapple, papaya, and figs have been used by both packers and consumers. When meat is cooked, the heat activates these tenderizers. Consumers buy tenderizers in liquid or powder form.

Sausage making. Packers make more than 200 varieties of sausage, but they use the same basic process to make most varieties. Meat is chopped or ground and mixed with seasonings and curing ingredients. Generally, this mixture is forced into *casings* (long tubes usually made from cellulose or from an animal protein called *collagen*). The casings are tied or twisted at regular intervals to form sausage links. Then the sausage may be smoked, cooked, or dried, depending on the type of sausage being made.

Some sausages are ready to eat. Others require cooking. The most popular is the frankfurter, also called the hot dog or wiener.

By-products

Modern production methods make it possible for meat packers to use much material that was once considered waste. In fact, packers are sometimes credited with using "every part of the pig but the squeal." Livestock producers would get less money for the animals they sell if meat packers depended only upon the sale of meat from the carcass to make a profit.

Manufacturers divide by-products into two classes: (1) edible by-products or variety meats and (2) by-products, such as animal hides, that are not eaten.

The variety meats of cattle include the heart, liver, kidney, tongue, brains, *sweetbreads* (thymus), and *tripe* (first and second stomachs). In addition to variety meats,

hogs yield edible by-products such as ears, feet, *chitterlings* (small intestines), and lard.

U.S. government inspection

The Wholesome Meat Act of 1967 requires each state to provide inspection equal to federal standards for packers who sell in and have plants in that state. The U.S. Department of Agriculture must impose federal inspection standards on all plants in a state if that state's inspection standards do not equal federal standards. The law also requires that all meat produced in one state and sold in another must be inspected by the U.S. Department of Agriculture.

The inspection process extends through each stage of preparation of meat for sale. Labels used on federally inspected meat products must be approved, and they must give complete and accurate information.

The Department of Agriculture inspects about 90 percent of all meat produced in the United States. It administers federal laws that control the slaughtering and dressing of animals, and the preparation of meat for sale. The Department of Agriculture also inspects meat and meat products brought into the United States from abroad and inspects the wholesomeness of meat exported to other countries.

Government inspectors, many of them veterinarians, examine each animal to be certain it is produced under sanitary conditions. They make sure that meat products are wholesome and *unadulterated* (have no improper substances added). Inspectors check the construction, equipment, and sanitation in slaughtering and processing plants. They also inspect plants that make prepared meats such as luncheon meats; frozen meat pies and dinners; and canned and dehydrated soups.

History

Meat packing in the American Colonies began to develop as an industry during the 1640's. Packing houses packed pork in salt for shipment to plantations in the West Indies. The number of packing houses grew as communities developed that did not produce their own meat animals. In most cases, a packing house then served only one small community. When that community's farms failed to produce enough livestock, animals were herded in from other communities.

Before 1850, packing plants operated only during the winter. Many meat-packing plants were connected with icehouses. Workers cut ice from rivers and lakes in winter, and stored it in icehouses for use in warm weather. Meat packing became a year-round business after artificial refrigeration was developed.

However, until the industry developed refrigerated railway cars, packing plants had trouble keeping meat fresh during the time needed to ship it to big Eastern cities. By the 1880's, meat packers had perfected refrigerated railway cars. In the early 1900's, inventor Frederick McKinley Jones developed a refrigeration process that could be used in trucks.

Modern meat packing also began during this period, when packers perfected assembly line production methods. In 1890, Congress passed a meat inspection law for meats to be exported. In 1906, a law was passed providing for federal inspection of meats shipped in interstate commerce.

Since 1945, several hundred meat-packing plants have been built in towns and cities close to the farms and ranches where livestock are raised. Companies have lowered their transportation costs by building packing plants where livestock are raised. Many plants which make prepared foods have been built in and near big cities. These plants supply the processed meats that are sold in neighborhood supermarkets, butcher shops, and grocery stores.

Since the 1950's, the increased use of machinery has helped speed up meat-packing operations. Mechanical developments include continuous-process, frankfurter-making machines; semiautomatic slicing and weighing systems for packaged bacon; and mechanical knives and saws. Mechanically refrigerated trucks and railroad cars have eliminated the need for ice and salt to preserve meat that is shipped long distances. Most meat packers now use computers in their production operations.

Trends in new product development include more prepackaging of retail meat items containing recipes and detailed cooking instructions, and more precooked meat products. Many meat packers offer the consumer canned meats—hams, luncheon meats, sandwich spreads, and combination dishes that consumers can store easily and serve quickly. Nearly all meat is sold in prepackaged form. Much of the meat is boned, shaped, and ready for cooking. New methods of breeding and feeding have produced younger animals of the desired market weight and quality. As a result, meat is leaner and more tender.

Mecca, *MEHK uh* (pop. 965,697), is the holiest city of Islam, the religion of the Muslims. It lies in western Saudi Arabia in a dry, barren valley that is surrounded by desolate hills and mountains (see **Saudi Arabia** [political map]). The city is the birthplace of Muhammad, the prophet of Islam. Mecca is also the site of the *Kaaba,* the shrine that Muslims face when they pray.

Only Muslims may enter Mecca, which Islam considers to be a sacred city. Islam requires every Muslim to make the *hajj* (a pilgrimage to Mecca) at least once if he or she is able to do so (see **Hajj**).

The city. The Great Mosque, the center of worship for all Muslims, stands in the heart of Mecca. The outside of the mosque consists of an *arcade,* a series of arches supported by pillars. The arcade encloses a courtyard that is about 600 by 800 feet (180 by 240 meters). The Kaaba, a cube-shaped stone building, is in this area. The Kaaba contains the Black Stone, which Muslims believe was sent from heaven by Allah (God).

In the 1950's, the Saudi government began a program to modernize Mecca. This program included the construction of tall, modern hotels for pilgrims. The government also added lighting and other facilities, built better roads, and increased the health and security services of the community. Modern houses replaced numerous traditional dwellings. New suburbs were also built, and

Keystone

The Great Mosque in Mecca is the center of worship for all Muslims. The Kaaba, Islam's most sacred shrine, stands in the mosque's courtyard. More than a million Muslims make a pilgrimage to the Great Mosque annually.

many wealthy Meccans moved to those areas. Mecca is the home of the Saudi Arabian Institute for Higher Education and of one of Saudi Arabia's royal palaces.

People. In the past, many Muslims who came to Mecca on the hajj settled there later. The city's population became a mixture of various nationalities. But since the 1930's, the government has strongly discouraged immigration to Mecca because it wants to preserve jobs in the area for people of Saudi Arabia.

Economy of Mecca depends on money spent by pilgrims. A hajj must be made between the 8th and 13th day of the last month of the Muslim year. About $1\frac{1}{4}$ million pilgrims crowd into Mecca within those few days. About half of them come from other countries. The city takes in more than $100 million during the annual great pilgrimage. The Saudi government spends almost $50 million yearly to provide health care, security, and other services for pilgrims.

Mecca has some minor industries. For example, a factory makes products from clay. But the city no longer plays a major part in Saudi Arabia's economy, which has been based on oil exports since the late 1940's.

History. Mecca became a trading center about A.D. 400. The people of Mecca worshiped many gods, whose idols stood at the Kaaba. Muhammad was born in the city about 570.

The Meccans rejected Muhammad's religious teachings, and he and his disciples fled from the city in 622. Eight years later, Muhammad and his followers captured Mecca and destroyed the idols. They spared the Kaaba, which has remained as the Muslim shrine.

Mecca became the heart of the first Arab-Islamic empire. The city's political importance declined during the mid-600's, when Muslim conquests spread through distant lands. But Mecca kept its importance as the religious center of Islam.

A series of *sharifs* (descendants of Muhammad) ruled Mecca from 960 until 1924. That year, Abd al-Aziz ibn Saud, an Arab leader, conquered the city. Mecca became part of his kingdom, which he named Saudi Arabia in 1932. Beginning in the 1950's, the Saudi government has worked to modernize Mecca and to ensure the comfort and safety of pilgrims to the city. During the 1970's and 1980's, Mecca experienced major population growth as many rural people moved there.

Malcolm C. Peck

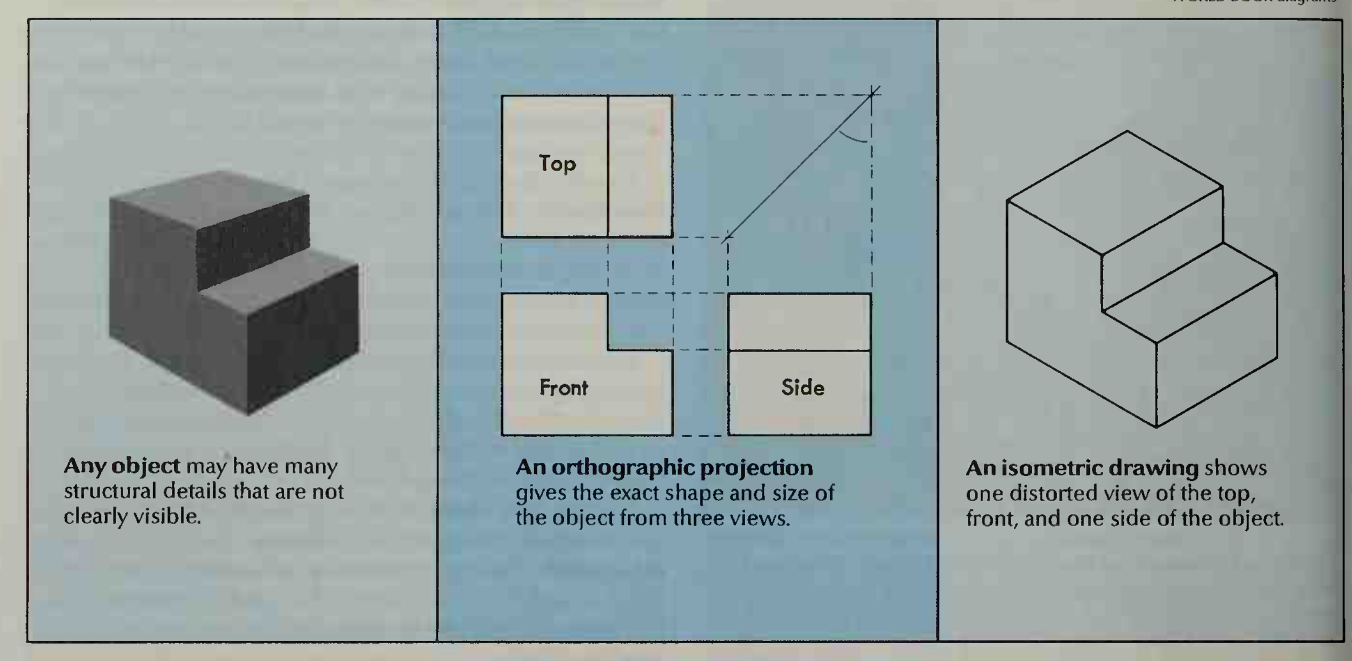
Mechanical drawing is a drawing that provides the exact information needed to produce an architectural structure or a manufactured object. Every building, bridge, and dam requires mechanical drawings, as does every automobile, refrigerator, and lathe.

Information in the drawing. Like a sketch, a mechanical drawing shows how an object should look. However, the drawing is made precisely to scale, and specifications of dimensions, angles, and other measurements are written on it.

The drawing also provides instructions for producing the object. For example, a mechanical drawing of a gear may specify how precise the dimensions must be, the material and heat treatment to be used, the surface finish, and settings for the machines that are to fashion the gear from metal.

Mechanical drawings represent the appearance of an object in different *views.* A view, also known as an *orthographic projection,* is made by drawing the various sides of a three-dimensional object on a flat plane such as the surface of a sheet of paper or a computer screen. In the United States, designers and *drafters* (specialists who prepare mechanical drawings) commonly use



SoftSource

Computer-aided drafting enables a designer to enter into a computer all the information needed to produce a mechanical drawing. The drawing may be printed out on a laser printer or a *digital plotter,* shown above behind the computer.

Mechanical drawing

Drafters prepare mechanical drawings to provide technical information. Unlike a photograph or a perspective drawing, a mechanical drawing presents various views of an object to define its dimensions. Common drafting methods include *orthographic projection* and *isometric drawing*.

WORLD BOOK diagrams

Any object may have many structural details that are not clearly visible.

An orthographic projection gives the exact shape and size of the object from three views.

An isometric drawing shows one distorted view of the top, front, and one side of the object.

third-angle projections, which consist of the top, front, and side views of an object.

Creating a drawing. A designer often begins the design process by sketching ideas on paper. The designer then develops these ideas on paper or on a computer. Today, most designers or drafters create the final mechanical drawing on a computer. But some still use traditional tools—such as compasses, curves, dividers, protractors, and T squares—to produce the drawing manually on paper, *Mylar* (a plastic film), or *vellum* (a high-quality paper). Some drafters use a *drafting machine,* a device that helps them draw precise vertical, horizontal, and angled lines.

The production of mechanical drawings on computers is called *computer-aided design and drafting* (CADD). A drafter using a CADD system selects commands from graphics software and other programs. The drawing appears on the monitor and is stored in the computer's memory. At some design firms, a networked computer system enables several different people to work on different parts of a single drawing. Drafters use a laser printer or a small *inkjet printer* (a device that squirts tiny drops of ink onto paper) to print most drawings. For large drawings, they may use a *pen plotter,* which inks a roll of paper with a number of precisely controlled pens; an *electrostatic plotter,* which works somewhat like an electrostatic copying machine; or an *inkjet plotter,* which is basically a large inkjet printer. The drawing can also be printed on photographic film.

In many cases, CADD makes it unnecessary to print a drawing. Workers who are going to produce a part can call up the drawings from computer memory and display them on their own monitors. In some instances, workers transmit the drawing electronically to a *computer-aided manufacturing* (CAM) *system.* This computerized device controls machines that produce the part.

Designers often use CADD software in the design process. They do this by producing a *three-dimensional model*—a photographlike drawing of the object on the monitor—then manipulating it in various ways. For example, they can change the object's dimensions. Or they can move the model about as if the object were rotating in space, thereby obtaining various views. The process of designing and creating mechanical devices on a computer is known as *computer-aided design* (CAD).

CAD provides additional advantages. For example, an architect can use CAD to "walk through" a model of a building before construction begins. Tin-Man Lau

See also **Blueprint; Computer graphics** (In engineering); **Industrial design.**

Mechanics is a science that studies the effects of forces on solids, liquids, and gases at rest or in motion. Engineers use mechanics to determine stresses and deformations in machine parts, such as gear teeth, and in structural elements, such as support columns. The principles of mechanics are used by engineers to design products that range in size from tiny computer parts to huge dams; by astronomers to predict the motion of stars, planets, and other celestial bodies; and by physicists to study the motion of atomic particles.

Mechanics can be divided into two branches—statics and dynamics. *Statics* studies bodies at rest, or in motion at a constant speed and in a constant direction. *Dynamics* is the study of bodies that undergo a change of speed or direction, or both, when forces act upon them.

Solid mechanics is the study of the motions of rigid bodies and deformable solid bodies, and of the forces that cause such motions. *Continuum mechanics* deals with deformable bodies. Deformable bodies are gases, liquids, and deformable solids. Areas of specialization in continuum mechanics include *theory of elasticity,* the study of the reversible deformation of solids; *theory of plasticity,* the study of the permanent deformation of solids; *fluid dynamics,* the study of fluids in motion;

aerodynamics, the study of gases in motion around a body; and *hydraulics,* the study of liquids at rest or in motion. James D. Chalupnik

See also **Aerodynamics; Dynamics; Fluid mechanics; Hydraulics; Statics.**

Mechanic's lien. See Lien.

Mechanist philosophy, *MEHK uh nihst,* states that physical phenomena must be explained in terms of laws of cause and effect that describe the motion of matter. Mechanist philosophers believe that all of nature can be understood by describing the size, shape, arrangement, and motion of small particles of matter called *atoms* or *corpuscles.* Many mechanists characterize their philosophy as the claim that the world is like a gigantic machine. Just as the interaction of cogs, springs, and wheels makes a machine work, so the interaction of tiny corpuscles or atoms ultimately causes all the different phenomena in nature.

Mechanism is opposed to the philosophical doctrine of *teleology.* Teleology comes from the Greek word *teleos,* meaning *goal* or *end.* A teleological theory seeks to understand physical phenomena in terms of purposes. For example, these two philosophies would give different answers to the question, "Why does fire travel upward?" A mechanist would explain that the atoms or corpuscles making up the fire collide, bouncing one another upward according to the laws of impact. The teleological answer would be that it is the nature of fire to blaze upward in search of its natural place above the earth.

During the 1600's, Thomas Hobbes and John Locke in England and René Descartes in France developed influential mechanistic philosophies as a reaction against teleology. During this time, mechanistic philosophy became an important part of the Scientific Revolution. But in the 1800's, physicists began to realize that mechanism was inadequate to explain such phenomena as electricity and magnetism. Thus, the original mechanistic goal of explaining all of nature in terms of matter and motion had to be abandoned. Douglas M. Jesseph

Mecoptera. See Insect (table).

Medals, decorations, and orders are honors that are awarded to people for bravery or merit. These honors are generally given by a monarch or head of state. People granted such honors receive a badge that may be worn or displayed. In most cases, the badges are suspended from a ribbon. The designs and colors of the ribbon usually symbolize the national colors of a country or such characteristics as virtue or bravery.

Medals are usually round and bear the likeness of a head of state or other symbol surrounded by an inscription. Most medals are made of gold, silver, or bronze. Medals generally hang from a ribbon. Medals are usually presented for participation in a campaign, long service, or good conduct. An example of a medal is the United States Navy Civil War campaign medal.

Decorations are usually in the shape of a cross or star, suspended from a ribbon. They are usually given in wartime for a single act of outstanding gallantry. In the military, decorations are generally more important than medals. The Victoria Cross of Great Britain is an example of a decoration.

Orders have a variety of shapes, but stars and crosses are used most frequently. The most common type of cross is the *Maltese cross.* Its four arms have V-shaped ends. Traditionally, orders have been exclusive societies with a limited membership determined by the head of state. In countries where orders exist, membership is generally considered the highest possible degree of honor. The United States and Switzerland are among the few countries that do not have orders. The French Legion of Honor is an example of an order.

United States medals and decorations

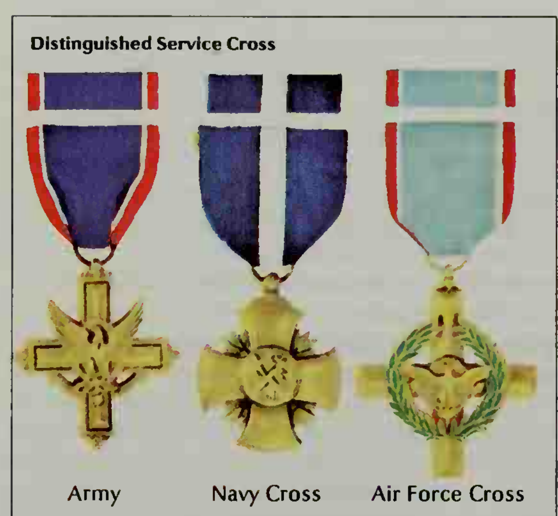
Military awards. During the late 1700's and early 1800's, the idea of medals and decorations was unpopular in the United States because it was associated with customs of the European upper classes. As a result, no general system of military medals or decorations was organized until the Civil War. However, a few individual awards were granted during the Revolutionary War. George Washington received the first American medal. In 1776, Congress gave him a gold medal for forcing the British to abandon Boston.

In 1782, Washington established the Purple Heart, formally called the Badge of Military Merit. This badge, which consisted of a heart made of purple cloth, was awarded to Revolutionary War soldiers for unusual bravery. The modern Purple Heart, established in 1932, is given to members of the armed forces who have been wounded or killed in action.

During the Civil War, Congress authorized the first permanent U.S. military medal or decoration—the Medal of Honor. Today this award, often called the Congressional Medal of Honor, is the highest military decoration that the United States grants to members of its armed forces. Congress approved the Navy Medal of Honor in 1861, and the Army Medal of Honor in 1862. Originally, the Army Medal of Honor was awarded only to noncommissioned officers and privates. Beginning in 1863, this honor was also given to officers. The Air Force Medal of Honor was approved by Congress in 1963. Before then, Air Force personnel received the Army Medal of Honor because the Air Force was originally part of the Army.

Campaign medals, also known as war service medals, have been awarded to all ranks of the military for service in every war fought by the United States from the Civil War to the present. The first campaign medal approved by Congress was the Manila Bay Medal, also called the Dewey Medal. This medal was awarded in 1898 to members of the Navy and Marine Corps who took part in the battle of Manila Bay during the Spanish-American War. The U.S. War Department authorized the Army Civil War Campaign Medal in 1907—42 years after the conflict ended.

Civilian awards. Congress established the gold and silver Treasury Department Lifesaving Medals in 1874. They are awarded by the Coast Guard for extreme and heroic daring in rescue at sea.



In 1904, Andrew Carnegie established the Carnegie Hero Fund Commission. The commission provides awards in North America and Western Europe for saving or attempting to save lives. Carnegie Medals have been awarded in gold, silver, and bronze.

United States civilian medals and decorations

Presidential Medal of Freedom	1963	U.S. citizens	Nation's highest civilian honor for exceptional merit toward national security, world peace, culture, or other public service
Presidential Citizens Medal	1969	U.S. citizens	Exemplary deeds of service
Gold and Silver Lifesaving Medals	1874	Any person	Lifesaving in maritime waters at personal risk of life
National Security Medal	1953	Any person	Distinguished contribution to the U.S. national intelligence effort
President's Award for Distinguished Federal Civilian Service	1957	Federal employees	Outstanding service
Young American Medal for Bravery	1950	U.S. citizens under 19	Exceptional courage in lifesaving
Young American Medal for Service	1950	U.S. citizens under 19	Outstanding service
Congressional Space Medal of Honor	1969	Astronauts	Exceptional meritorious contribution to national welfare
National Aeronautics and Space Administration Distinguished Service Medal	1959	Federal employees	Contributions to aeronautical or space exploration

awarded to distinguished U.S. citizens. Recipients have included composer Irving Berlin and comedian Bob Hope. The Defense of Freedom medal primarily honors civilian Department of Defense employees injured or killed in the line of duty. Another medal, the Presidential Medal of Freedom, is the nation's highest civilian honor. It is awarded by the president for outstanding service.

Foreign orders and decorations

Medals and decorations are awarded by nearly every country in the world. Most nations have national orders of merit. The highest awards for valor or service in some countries are the grand orders of knighthood. New systems of awards have developed as kingdoms have been replaced by other forms of government. Many former colonies that are now independent also have set up their own systems of awards.

The Americas. Mexico awards the Order of the Aztec Eagle to foreigners who have given distinguished service to Mexico. Bolivia's highest award is the National Order of the Condor of the Andes. It is given to foreigners and Bolivian citizens for exceptional civil or military merit. Peru awards the Order of the Sun of Peru to Peruvians and foreigners for distinguished service in civilian or military affairs.

Europe. The Victoria Cross is the highest honor in the United Kingdom. Queen Victoria instituted this award in 1856. It is usually given to members of the military for a single act of extreme heroism. The United Kingdom's Royal Humane Society is probably the world's best-known lifesaving society. Each year, this society grants over 50 medals for lifesaving. France's highest award is the Legion of Honor. This award was instituted by Emperor Napoleon I in 1802. It is given to foreigners and French citizens for gallantry or civil achievement. The Legion of Honor was the first order based solely on merit and was open to all citizens. One of the oldest European awards is Denmark's Order of the Dannebrog. It was established in 1219 and revived in 1671. It is given to Danes and foreigners for distinguished service in civilian and military affairs.

Middle East. Lebanon gives the National Order of the Cedar to foreigners and to Lebanese for exceptional service or for acts of extreme courage. Egypt's highest award is the Order of the Nile. This award is given to Egyptian citizens and foreigners for distinguished military or civilian service. Israel gives the Medal for Valour to members of the Israeli military who have performed acts of supreme heroism.

Africa. Gabon awards the Order of the Equatorial Star for acts of courage or devotion to duty and for contributions to the work of the country. Kenya awards the Order of the Golden Heart of Kenya to citizens of Kenya and foreigners who have performed exceptional service

to the country. Morocco's highest award is the Order of Muhammad. This award is given to members of the royal family, foreign heads of state, and civil and military leaders for exceptional service to Morocco. Malawi gives the Order of the Lion of Malawi to foreigners and citizens of Malawi who have performed distinguished and outstanding service to Malawi. The Order of the Pioneers of Liberia is Liberia's award for exceptional service to Liberia in the arts, science, or government, as well as for heroism.

Australia and Asia. Australia's highest award, the Order of Australia, is given to Australians and foreigners for outstanding civil or military merit. India awards the Bharat Ratna (Jewel of India) to Indian citizens who have done exceptional work in art, literature, science, or public service. Thailand's greatest honor is the Most Illustrious Order of the Royal House of Chakri. Membership is limited to 43 people who have done outstanding service to Thailand. The Supreme Order of the Chrysanthemum, Japan's highest award, is given to Japanese royalty, nobility, and foreign heads of state (male only).

History

Since the beginning of history, monarchs and heads of state have rewarded individuals for bravery and merit. The ancient Greeks rewarded military and athletic heroes with wreaths made of laurel leaves. The tradition of the wreath has had a lasting influence. Today, many medals have an image of a laurel wreath around an inscription or the *bust* (sculpted head) of a head of state.

The ancient Romans crowned their heroes with gold laurel wreaths. Gold collars, chains, medallions, and arm rings were also awarded for outstanding bravery. The most significant award was the *phalera,* a gold or silver disk formed into the head of a god, man, or animal. These awards were given for bravery in battle and represented an early stage in the development of breast stars and chest decorations.

Knights of the Middle Ages formed orders. Each order had a distinctive badge showing the order's symbol. A knight wore the badge on a chain around his neck. Knights also received medals of gold, silver, or bronze. These round medals were meant for display on a table.

Medals, decorations, and orders of some other countries

Country	Name of award	Year established	People eligible	Awarded for
Belgium	**Order of Leopold**	1832	Belgians and citizens of other countries	General civilian and military merit
Brazil	**National Order of the Southern Cross**	1822	Citizens of other countries	Civil or military merit
Canada	**Order of Canada**	1967	Canadian citizens	Outstanding achievement in any field

Syria	**Order of the Omayyad**	1924	All people	Outstanding civil or military merit
Turkey	**Independence Medal**	1924	Turkish citizens	Outstanding contribution to the formation of the Turkish Republic
United Kingdom	**Order of the Garter**	1348	Sovereign and 26 knights	Service to the British monarch
	Victoria Cross	1856	All ranks of the armed forces	Conspicuous bravery in action
Vatican	**Order of Pius**	1847	Distinguished Roman Catholics	Personal service to the pope

The first ribboned medals, similar to today's medals, appeared in Austria and Russia in the 1600's. Most of these medals celebrated participation in famous battles and were generally awarded only to military officers.

By the mid-1800's, almost every country in Europe had at least one order for merit. Orders were created to reward merit in many fields, including the arts, science, and agriculture, as well as military and civil merit. During the late 1800's, trade and the expansion of colonial empires led many countries to adopt awards systems based on those of Western Europe. James Robert Elliott, II

Medea, *mih DEE uh,* a woman in Greek mythology, had magical powers. She helped the hero Jason capture the Golden Fleece, the golden wool of a flying ram.

Medea was the daughter of Aites, the king of Colchis. The Golden Fleece hung in a grove of trees there, guarded by a dragon that never slept. Medea fell in love with Jason when he and his companions, the Argonauts, came to Colchis to capture the fleece. She put a spell on the dragon so Jason could take the fleece.

Medea and her brother, Apsyrtos, sailed from Colchis with Jason and the Argonauts. When Aites tried to overtake them, Medea killed Apsyrtos and cut him into little pieces, which she threw into the water. The king stopped to recover the pieces of his son's body, and Jason and Medea escaped. The expedition traveled to Iolkos, the Greek city where Jason had been born. There, Medea plotted against King Pelias, who had seized the throne of Iolkos from Jason's father. She told the king's daughters that she had a magic charm to make the king young again. However, Medea withheld the correct ingredients. The daughters tried the magic on the king, and he died. The king's son forced Jason and Medea to flee, and they settled in the city of Corinth.

Jason and Medea had two children and lived happily in Corinth for 10 years. But then Jason fell in love with Glauke, also called Creusa, the daughter of the king of Corinth. He left Medea and prepared to marry Glauke. Medea gave her rival a magic robe that burned Glauke to death when she put it on. Medea then killed the two sons she had by Jason and fled to Athens.

Medea lived with Aegeus, the king of Athens, and they had a son named Medus. When the king's first son, Theseus, came to Athens, Medea feared he would replace Medus as the heir to the Athenian throne. She tried to poison Theseus, but Aegeus learned about the plot and banished Medea. Medea returned to Colchis, where she lived the rest of her life.

Medea is the central character in tragedies by the ancient Greek playwright Euripides and the Roman author Seneca. Her story is also told in *Médée* (1635) by Pierre Corneille of France and in *Medea* (1946) by the American poet Robinson Jeffers. John Hamilton

Medeiros, *may DAY rohs,* **Humberto S. Cardinal** (1915-1983), was appointed a cardinal of the Roman Catholic Church by Pope Paul VI in 1973. Medeiros was born on São Miguel Island in the Azores on Oct. 6, 1915. He immigrated to the United States in 1931 and became a U.S. citizen in 1940. Medeiros was ordained a priest in 1946. In 1966, he became bishop of Brownsville, Texas. He supported Mexican American farmworkers who were campaigning for higher wages. Medeiros was named archbishop of Boston in 1970. Kenneth Guentert

Medellín, *meh deh YEEN* (pop. 1,834,881), is the second largest city of Colombia. Only Bogotá has more people. Medellín is in northwestern Colombia, nearly 5,000 feet (1,500 meters) above sea level in a lovely valley east of the Cauca River. For location, see **Colombia** (map). Medellín is a center of Colombia's industrial activity. Factories there produce most of the country's textiles, as well as clothing, processed food, agricultural machinery, glass and china, paints, and chemicals. Medellín has four universities. Residential neighborhoods and modern industrial parks surround the city.

Medellín was founded in 1675 near gold fields. Later, the area became noted for its coffee production. Medellín is a chief center for illegal drug trade in Colombia. Beginning in the 1980's, fighting between drug dealers and police took place there. For more information, see **Colombia** (Colombia today). William J. Smole

Media, *MEE dee uh,* was an ancient country that flourished in the 500's B.C. in what is now northern Iran. Media was inhabited by the Medes, an Indo-European people who had come to the region from the north about 1000 B.C. Assyria, a powerful country to the west, invaded Media in 836 B.C. Many other Assyrian invasions of Media followed. The Medes formed a unified state about 700 B.C. and established their capital at Ecbatana (now Hamadan, Iran). They reached the peak of their

WORLD BOOK map

Location of Media

power under Cyaxares, who reigned from 625 to 585 B.C. Cyaxares defeated Assyria and built an empire that included parts of what are now Afghanistan, Iran, Pakistan, and Turkey. Astyages, the son of Cyaxares, was the last Median king. He was defeated by Cyrus the Great of Persia about 550 B.C. Cyrus incorporated Median lands into the Persian Empire and made Media a Persian province. Norman Yoffee

Median, *MEE dee uhn,* in statistics, is the middle value in a group of numbers arranged in numerical order. Suppose five students receive test scores of 62, 84, 99, 77, and 88. To find the median of these scores, arrange them in numerical order: 62, 77, 84, 88, and 99. The number in the middle is now 84. The *median* of this group is 84, and the *median score* is 84. The *arithmetic average* or

mean score is 82. If the number of cases is even, there will be no number in the middle. In such instances, the median is the average of the two middle values. If the median mark on a test is 84, we know that just as many students received marks above 84 as marks below 84.

Doris F. Hertsgaard

Medic Alert is a metal emblem that identifies its wearer as someone who has a certain medical problem. Such a problem may be a drug allergy, diabetes, heart disease, or some other condition that a doctor should know about before giving medical treatment. For example, people with severe allergies may become seriously ill or die if they take certain drugs. Such people might someday require emergency care while unconscious. If they wear a Medic Alert emblem that identifies their problem, the doctor will not give them the drugs. The emblems are provided in the form of necklaces or bracelets by the Medic Alert Foundation International, a nonprofit organization.

Critically reviewed by the Medic Alert Foundation International

Medicaid is a United States government program that works in cooperation with state governments to partly finance medical assistance to needy people. Individual state governments administer their own state Medicaid programs, and the federal government pays a portion of the states' costs. Within broad federal guidelines, states have considerable freedom to define who is eligible and what categories of medical services are covered. However, all state programs must meet certain basic standards in order to receive federal funding.

Federal law requires that states extend Medicaid eligibility to some *categorically needy* groups. These groups include elderly and disabled people who receive support from certain other federal assistance programs, as well as certain low-income families, children, and pregnant women. In addition, states have the option to provide coverage for other groups, including those considered *medically needy.* Medically needy groups may include people with incomes above the usual eligibility levels who need assistance with large medical expenses.

Services generally covered by Medicaid include basic hospital services, nursing home care, home health care, vaccines for children, laboratory and X-ray services, and *prenatal care* (medical treatment during pregnancy). States may also fund additional services, such as optometrist care, physical therapy, and prescription drugs.

State Medicaid programs set payment rates for health care services. Many state programs pay for services through managed care health insurance plans such as health maintenance organizations (HMO's). Federal law does not require that health care providers participate in Medicaid, but, if they do, they must accept Medicaid payment rates. States may require some Medicaid recipients to pay a small share of the costs of certain services.

Congress established Medicaid in 1965 as an amendment to the Social Security Act of 1935. The Health Care Financing Administration (HCFA) oversees the program on the federal level. The HCFA is a division of the U.S. Department of Health and Human Services.

Medical ethics is the field of study concerned with moral problems created by the practice of modern medicine. Medical ethics is divided into three branches: (1) public policy medical ethics, (2) biomedical ethics, and (3) clinical ethics.

Public policy medical ethics deals with issues related to the regulation of medical practice by governments and by the governing boards of such institutions as hospitals and nursing homes. For example, federal and state governments establish spending limits for public health care. These limits raise ethical questions about the type and extent of medical services available to people who depend on public funds to pay medical bills. Other problems involving public policy include the control of medical research, the question of whether all citizens have a right to health care, and the availability of drugs for severe illnesses, such as AIDS.

Biomedical ethics addresses moral questions that arise from the use of medical technology to begin or maintain a life. Many ethical questions focus on medical procedures that affect human reproduction. These include *in vitro fertilization* (starting human life in a test tube), the *cloning* (duplication) of human embryos, abortion, and procedures that alter the genes of a fetus. Another important issue is *euthanasia,* the practice of painlessly putting to death people who are hopelessly injured or terminally ill.

Clinical ethics evaluates the morality of decisions about medical care made by or with patients and their families. Problems of clinical ethics include deciding whether or not to remove life-sustaining treatment, making medical decisions for a newborn with severe mental retardation or an unconscious person, and dealing with requests for euthanasia from patients or their families.

All three branches of medical ethics relate to one another. For example, patients with AIDS are concerned with the availability of newly developed medications (public policy medical ethics), participate in arguments about whether or not physicians are obligated to treat them (biomedical ethics), and make decisions about their care and death with loved ones and physicians (clinical ethics). David C. Thomasma

Medical examiner is a public official who investigates suspicious or unnatural deaths. He or she determines the cause of death and whether the death may have resulted from a crime. Medical examiners are physicians appointed by the state or local government.

In some states and local districts of the United States, the public official who investigates suspicious or unnatural deaths is called a *coroner.* Most coroners are elected. In a case of suspicious death, the coroner conducts an inquiry called an *inquest.* A coroner's jury may hear the evidence and decide whether the death resulted from a crime. The jury's verdict is not conclusive but may become the basis of a murder indictment. In areas with medical examiner systems, public prosecutors handle the legal aspects of homicide investigations.

Since the 1960's, the medical examiner system has replaced the coroner system in many states. Many people

question the reliability of the coroner system because elected officials may lack the needed medical and legal training for the job. Edmund R. Donoghue

See also **Autopsy; Inquest; Jury** (Coroner's juries).

Medicare is a United States government health insurance program that covers nearly all people age 65 or older. It also covers certain people with kidney disease and people who have received Social Security disability benefits or Railroad Retirement Board disability benefits for at least two years. The Railroad Retirement Board is a federal agency that administers a pension system for railroad employees.

Medicare consists of two types of insurance—hospital insurance and medical insurance. Hospital insurance helps pay the cost of hospital care, certain skilled nursing facility care after leaving the hospital, and home health services. Medicare also has an optional *hospice* benefit that is available for terminally ill patients. Hospice is a type of home-centered health care for people dying of an incurable illness. Medicare hospital insurance is financed by a tax paid by workers and their employers and by self-employed people.

Medicare medical insurance helps pay for physicians' services and certain other costs not covered by hospital insurance. Medical insurance is financed by the federal government and by monthly payments from members.

Eligible people can get Medicare coverage by signing up at a Social Security Administration office or, if appropriate, a Railroad Retirement Board office. Medicare beneficiaries normally must pay premiums and some of their own medical expenses. But for certain low-income people, a welfare program called Medicaid pays part or all of these premiums and expenses. Medicare is managed by the Health Care Financing Administration of the U.S. Department of Health and Human Services.

Medici, *MEHD ih chee,* was the name of a ruling family of Florence, Italy. Members of the family played important parts in the history of Italy and France from the 1400's to the 1700's. Their great wealth and influence as bankers gave them control of Florence.

Except for brief periods, the Medici ruled Florence from the early 1400's to 1737. Their cultural interests led them to become patrons of the arts, and Florence became an art center under their rule. Michelangelo and Raphael were among the artists the Medici helped.

Giovanni de' Medici is considered the first great Medici. He made a fortune in banking and commerce in the late 1300's. His son Cosimo de' Medici became the first Medici to win wide fame. He ruled Florence from 1434 to 1464 and gave large sums of money for the arts. Cosimo's grandson Lorenzo de' Medici was the most famous Medici. Called "Lorenzo the Magnificent," he ruled Florence from 1469 to 1492. Under him, Florence achieved its greatest splendor and was one of Italy's most powerful cities.

The Medici influence extended to Rome when three members of the family became popes. Leo X reigned from 1513 to 1521 and Clement VII from 1523 to 1534. Leo XI was pope for only 27 days in 1605. Two women of the Medici family became queens of France. They adopted the French spelling of the name, *de Médicis.* Catherine de Médicis, the wife of Henry II and mother of three French kings, was a powerful force in France from 1559 until her death in 1589. Marie de Médicis married Henry IV. After his death in 1610, Marie ruled until her son Louis XIII took over. Paul F. Grendler

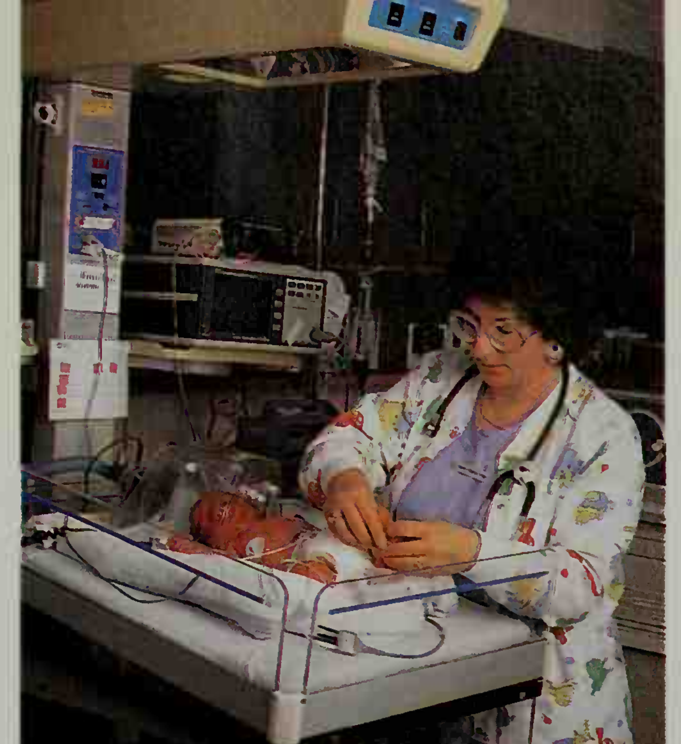
Medici, *MEHD ih chee,* **Cosimo de',** *KAW zee maw day* (1389-1464), was a wealthy banker who ruled Florence, Italy. He was an important patron of artists and writers during the Renaissance, a revival of interest in classical culture that began in the 1300's.

Cosimo was born in Florence. Like his father, Giovanni de' Medici, he was a banker and merchant. Cosimo built up his father's fortune, and his banks spread all over Europe. Many Florentines looked to him for leadership in government affairs. Others feared his ambition. In 1433, the city's ruling group drove him from Florence. But this group later lost power, and Cosimo returned in triumph in 1434. He ruled Florence from then until his death, though he rarely held an official title. People recognized his authority because he gave good advice and had many supporters in the city.

Cosimo loved good art and literature and was a shrewd judge of talent in painters and writers. He founded libraries and built a magnificent palace. The palace, the libraries, and the art that he supported helped beautify Florence. Paul F. Grendler

Medici, *MEHD ih chee,* **Lorenzo de',** *law REHN tsaw day* (1449-1492), ruled Florence, Italy, from 1469 until his death. He was a leading statesman of the Renaissance, a period of great cultural achievement in Europe. Lorenzo also wrote poetry and helped and encouraged other artists. During his rule, Florence achieved great splendor as a center for the arts.



Lorenzo was born in Florence. Like his father, Piero de' Medici, and his grandfather Cosimo de' Medici, he ruled Florence without holding an official title. In 1479, the pope and the city of Naples began a war against Florence. Later that year, Lorenzo arranged a treaty that stopped the war. After that, he pursued a policy of peace in Italy. At home, Lorenzo did not tolerate opposition. In 1472, he brutally put down a minor revolt in Volterra, a town ruled by Florence.

Lorenzo was well educated and an excellent poet. He surrounded himself with scholars and artists. For these reasons, he is sometimes called "the Magnificent." But he neglected the bank that had earned his family's fortune. Soon after his death, the bank ran out of money and closed. Paul F. Grendler

Advanced medical care enables patients to recover from many illnesses that once caused death. In this picture, a nurse cares for an infant in a special hospital unit for critically ill babies.

Medicine

Medicine is the science and art of preserving health and treating illness. Medicine is a science because it is based on knowledge gained through careful study and experimentation. It is an art because its success depends on how skillfully medical professionals apply their knowledge in dealing with patients.

The goals of medicine include saving lives, relieving suffering, and maintaining the dignity of sick people. These goals have made medicine one of the most respected professions. Thousands of men and women who work in medicine spend their lives caring for the sick. When disaster strikes, health workers rush emergency aid to the injured. When epidemics threaten, doctors and nurses work to prevent the spread of illness. Medical researchers search continually for better ways to prevent and treat disease.

Illness has existed since human beings and their ancestors first appeared on earth. Through most of human existence, people knew little about how the body works or what causes disease. Treatment was based largely on superstition and guesswork. People slowly gained their first accurate ideas about health and illness as the great ancient civilizations arose in the Middle East, India, China, Greece, and Rome.

In the last few centuries, medicine has progressed greatly. Medical workers have improved health care for adults and children and brought many infectious diseases under control. Thousands of new drugs and procedures have been developed. These advances, combined with better nutrition, sanitation, and living conditions, have given people a longer life expectancy. In the mid-1900's, most people did not live past the age of 50. Today, the worldwide average life span is about 65 years, according to the World Health Organization.

Medical care is often considered part of the larger field of health care. In addition to medical care, health care includes the services provided by dentists, clinical psychologists, social workers, physical and occupational therapists, and many other professionals. This article deals chiefly with the kind of health care provided by doctors and by people who work with doctors.

Marc B. Garnick, the contributor of this article, is Professor of Medicine at the Beth Israel Deaconess Medical Center of Harvard Medical School and Executive Vice President at Praecis Pharmaceuticals, Inc., a biotechnology firm.

Medicine protects public health with such broad measures as vaccination campaigns and tests to screen for illness. This Indian child receives an inoculation to prevent measles.

Elements of medical care

Medical care has three main elements: (1) prevention, (2) diagnosis, and (3) treatment.

Prevention of disease is a broad social goal that requires the cooperation of governments, medical workers, and patients. Preventing illness avoids suffering and costs less than treating many ailments. Some wide-ranging preventive measures, such as purifying drinking water, are most effectively carried out by governments. Doctors provide many treatments that help patients avoid illness. For example, they vaccinate people against polio, measles, and other diseases. Another way that doctors prevent disease is by educating patients and explaining medical issues. Physicians also encourage patients to make healthy choices, such as eating a nutritious, low-fat diet and avoiding smoking. Most doctors recommend that patients have regular checkups. These examinations may prevent serious illness by enabling doctors to diagnose and treat disease in its earliest stages.

WORLD BOOK photo by Ralph J. Brunke

Basic tools of medicine include these devices used in office examinations. These tools help health care professionals evaluate a patient's condition and determine if more tests are needed.

Diagnosis is the process of identifying the condition or illness that causes a patient's distress. In many cases, a variety of ailments could account for particular symptoms. For example, chest pain might be due to indigestion, muscle strain, or blockage of one of the heart's main blood vessels. To make a diagnosis, doctors first gather information about a patient by taking a medical history and performing an examination. They may obtain more information with medical tests. Doctors then use their skill, experience, and judgment to arrive at the diagnosis that best accounts for all the facts.

Doctors obtain a medical history by questioning patients. They ask about the symptoms that brought the patient to the doctor, past illnesses, and the health of family members. They also ask about habits and practices that affect health, such as whether a patient smokes.

A physical examination provides more information about a patient's condition. In a routine office examination, doctors can observe skin tone and evaluate the general condition of muscles and nerves. They can press and probe the body to check internal organs for unusual texture, size, or shape. Certain instruments can be used routinely to reveal conditions inside the body. For example, a stethoscope enables doctors to listen to a patient's chest and hear abnormalities in heartbeat or breathing.

When the history and routine examination do not provide enough information to make a diagnosis, a doctor may order more advanced tests. For example, such technologies as *magnetic resonance imaging* (MRI) can provide extremely detailed views of internal organs. Laboratory tests also aid diagnosis with chemical analysis or microscopic examination of blood, other body fluids, and tissues. If a diagnosis is difficult, a doctor may seek opinions from other doctors.

Treatment. Correct diagnosis provides the basis for successful treatment. Sometimes no treatment is required, and a doctor simply reassures a patient that the body will heal itself. At other times, prompt and accurate treatment prevents suffering and deadly complications.

A doctor studies X rays of a patient's breasts for evidence of lumps or others signs that may indicate cancer. This kind of special X-ray image is called a *mammogram.* X-ray machines and other devices help doctors diagnose and treat illnesses and injuries.

For example, early appendicitis usually causes a somewhat vague symptom—stomach pain near the navel that may stop, then start again. But delay in diagnosing and removing a diseased appendix may lead to widespread infection or, in extreme cases, death.

The number of treatments available grows constantly as medical knowledge advances. Some of the dozens of common treatments are listed under the *Treatment* section in the *Related articles* list at the end of this article.

When doctors make an incorrect diagnosis or provide improper treatment, patients may sometimes sue them for *malpractice*. A successful malpractice suit proves that a doctor is guilty of an extremely serious medical mistake that qualifies as *negligence*. Negligence is treatment that falls below the level of care that patients should reasonably expect from a skilled, competent doctor.

Medical professionals

In the United States, Canada, the United Kingdom, and other developed countries, medicine has become more complicated as it has progressed. In most cases, a doctor makes the major decisions regarding care of patients. Traditionally, all doctors received general medical training and treated all types of patients. Sick people received most care in their homes from one doctor who treated the whole family. Then, during the late 1800's and early 1900's, hospitals began to provide a better environment than homes for seriously ill patients. Family doctors began to admit patients to hospitals to take advantage of such features as skilled nursing care and operating rooms. But family doctors continued to oversee care of their hospitalized patients single-handedly.

Specialty care physicians. As medical knowledge progressed, physicians found it increasingly difficult to keep up with important advances in the whole field of medicine. Doctors began to spend their final years of training concentrating on a limited area of treatment. This narrow focus is called *specialization*. The area on which doctors focus is called their *specialty*. For example, *cardiology* is the specialty that deals with diseases of the heart and circulatory system. Specialization en-

Home care workers bring medical services to people at home. Home care enables older adults, such as this woman, to avoid some costly, physically difficult trips to doctors' offices.

Skilled technicians play a key role in modern medicine. Some help perform complicated procedures and operate sophisticated hospital equipment. In this picture, technicians assist in a diagnostic procedure that produces images of blood vessels.

ables doctors to become experts in a limited area and keep up with advances in that area throughout their professional lives. The table *Major medical specialties* in this article lists some important fields of medical concentration.

Many patients now receive care from a doctor who is an expert in their illness or from teams of health professionals. For example, many cancer patients receive treatment from several doctors. Cancer specialists include *medical oncologists* who prescribe cancer drugs, *radiation oncologists* who shrink tumors with radiation, and *surgical oncologists* who have special skill in cancer surgery. Cancer care teams may also include such additional members as specially trained nurses, social workers, and rehabilitation counselors.

Primary care physicians. Specialties that focus on providing basic medical treatment are called *primary care specialties.* Like yesterday's family doctors, primary care specialists treat a wide range of ailments. But today's primary care doctors receive more extensive training than did yesterday's family doctors. Part of today's training teaches primary care doctors to recognize cases that require the additional skills of a specialist. In the United States, primary care specialties include *internal medicine,* in which doctors focus on the general medical needs of adults; *pediatrics,* in which doctors specialize in treating children; and *family practice,* in which doctors care for all members of a family. In Canada, family practice is the only primary care specialty. In the United Kingdom, primary care doctors are called *general practitioners.*

Other health care professionals in addition to doctors help provide medical care. Registered nurses work closely with doctors in clinics, hospitals, and offices. A growing number of nurses also work independently to provide many services formerly provided only by doctors. For example, *nurse-practitioners* are registered nurses with additional training and certification. Their additional qualifications enable them to provide many types of basic primary and specialty care. When doctors prescribe drugs, *pharmacists* fill the prescriptions and may give advice on the drugs prescribed. The section *Other careers in medicine* discusses various nonphysician medical workers.

Providing medical care

Providing health care for citizens is a major social goal in most countries. Governments concern themselves with medical care because healthy citizens are happier and more productive than sick people are. People who are ill may not be able to work, attend school, or perform other tasks important to national well-being. But as worldwide life expectancy increases, health care grows more expensive. More people become ill with ailments that tend to strike as people age, such as arthritis, cancer, and heart disease. Researchers constantly develop new drugs and procedures to treat these conditions. But many such treatments involve costly, long-term care.

Paying for medical care challenges societies in two important ways. First, countries must find a means to limit the total cost of health care to a reasonable portion of their national wealth. Societies must pay for health care and still have enough money for education, military defense, transportation, and other social needs.

Second, countries must protect individual citizens from severe financial hardship caused by the cost of serious illness. Providing such protection requires spreading the cost of medical care among large groups that include both sick and healthy people. Some nations pay for medical care with general taxes. General tax funding spreads medical costs among all of a nation's taxpaying citizens. In other countries, citizens are protected with various types of public or private insurance. Insurance collects payments called *premiums* to spread costs among all the individuals in a particular insured group.

This section discusses the different ways that the United Kingdom, Canada, and the United States provide and pay for health care. A brief discussion of health care in other countries concludes the section.

The United Kingdom has a health care system called the National Health Service (NHS) that provides medical care free to all citizens. The NHS is funded mainly by

general taxes. Employed people make an additional contribution through a national insurance plan.

Everyone in the United Kingdom registers with a primary care doctor called a *general practitioner.* People can register with any general practitioner (GP) of their choice. Most GP's work in small groups and see patients in offices called *surgeries.* People consult their GP's whenever they need medical care. When a GP determines that a patient requires specialized care or treatment in a hospital, the GP refers the patient to a specialist. Patients cannot consult specialists without a referral from a GP except in an emergency. All specialists in the United Kingdom work in hospitals. When a specialist has completed a patient's treatment, the specialist sends the patient back to the GP.

Both GP's and specialists are paid by the National Health Service. In addition, the NHS provides many community support services, including nurses, ambulances, and certain types of home care.

The NHS holds down the cost of health care by emphasizing primary care and by limiting the number of hospitals. The number of doctors is also controlled by budget constraints and other factors that limit the number of admissions to medical schools. Specialists must go through additional training, then compete for a hospital post in their specialty when a position opens. The NHS controls where GP's can practice to ensure that medical care is available in all geographic areas.

Canada has a national medical care program that is commonly called *medicare.* (The United States also has a public health care program whose formal name is Medicare. The U.S. Medicare program is discussed in the *United States* section that follows.) Canadian medicare provides free care to all citizens through the joint efforts of the federal and provincial governments. The federal government gives general tax dollars to the provinces to finance medical care and certain other programs. The amount of this federal funding declined greatly in the 1990's. Each province decides how to obtain the rest of the money needed to pay for its medicare program. Some provinces collect additional taxes. Others create required insurance programs for people who can afford to pay something.

Each province negotiates with doctors to determine the fees that medicare will pay for different services and procedures. Patients may see any doctor whenever they feel that they need medical care. The province then pays the doctor the fee agreed upon for the care given.

In Canada, family practice physicians are the only primary care doctors. Internal medicine and pediatrics are grouped with other specialties. Both family practitioners and specialists see patients in offices and hospitals. Patients may consult specialists directly, without a referral from a family practitioner.

Canada's federal government and the provinces cooperate to coordinate training and placement of doctors. Medical schools in all the provinces have limits on the number of students they can accept each year. A national committee coordinates education after medical school to ensure that about half of Canada's doctors are trained as family physicians. All of Canada's hospitals are controlled by the provincial governments.

The provinces use various means to discourage doctors from flocking to large cities. City practice appeals to most doctors because cities have large, well-staffed hospitals and many other doctors to offer personal and professional support. But concentration of doctors in cities tends to leave rural areas without enough medical care.

The United States has no comprehensive national system for providing medical care. United States citizens receive medical care under many different private and public arrangements. The U.S. government plays a smaller role in providing health care than do the governments of most other developed countries.

The two principal government-operated health care programs in the United States are Medicare and Medicaid. Medicare is a national two-part program chiefly for adults over 65 years old. Medicare Part A, which pays for hospital care, is funded with a form of general taxes. Medicare Part B, which pays for doctors' services, charges participants a monthly fee.

Medicaid is a program that pays doctor and hospital bills for people who receive public income assistance. Medicaid is funded with federal and state tax dollars and is administered by the states.

The most widespread U.S. health care plan is private health insurance. In some cases, individuals buy private insurance. But most people with private health insurance purchase it as members of a group. The most common groups are based in places of employment. Such groups include all the people employed by a particular company or all the workers in a government office.

Private health insurance became the dominant U.S. health care program about the time of World War II (1939-1945). During the war, the U.S. government enacted wage and price controls that prevented employers from giving workers raises. To attract workers, employers began to offer indirect forms of pay called *benefits.* Paying for employee health insurance quickly became one of the most attractive benefits that employers could provide. Because of its popularity, the practice continued after the government lifted wage and price controls. Most employers still pay all or part of the cost of health insurance for their workers.

Public and private health care programs in the United States use two main methods of paying for health care: (1) fee-for-service plans and (2) managed care systems. In addition, U.S. citizens pay personally—also called *out-of-pocket payment*—for much of their medical care.

Fee-for-service plans pay doctors and hospitals for individual medical procedures. Fee-for-service payment was the most common system of paying for care from the end of World War II to the 1990's. People with fee-for-service insurance freely consult any primary care doctor or specialist of their choice. The chosen doctors decide what care the patient needs, provide treatment, and submit bills for each medical service. Hospitals submit similar itemized bills. The health care plan then pays doctors and hospitals based on the amounts charged. Most fee-for-service plans do not pay for some services and pay only a portion of the cost of others.

Medicare and Medicaid have traditionally somewhat resembled fee-for-service programs. Medicare and Medicaid patients are free to choose their own doctors. But both programs pay doctors according to fee schedules decided by the government. Medicare pays hospitals by classifying ailments into a system of hundreds of categories called *diagnosis-related groups* (DRG's).

© Jeremy Hartley, Panos Pictures

In less developed countries, many medical efforts focus on meeting citizens' basic health needs. Here, medical workers in the African country of Sierra Leone teach mothers how to make a nutritious food supplement for their babies.

Medicare pays a fixed amount for each DRG by calculating the average cost of treating that ailment.

Many Medicaid fees fall considerably below doctors' usual charges. Because of these lower fees, some doctors and hospitals will not accept Medicaid patients.

Fee-for-service medicine offers patients great personal choice and doctors great independence. But choice and independence also make the system expensive. As in other countries, an aging population and advancing medical technology are increasing the cost of medical care. The fee-for-service system tends to encourage unrestricted use of medical services. The United States spends a higher percentage of its national wealth on medical care than does any other country. Efforts to reduce the percentage of U.S. wealth spent on medical care have centered on a system called *managed care.*

Managed care tries to reduce costs by coordinating care and controlling patients' ability to use doctors and services. One important type of managed care plan is a *health maintenance organization* (HMO). An HMO controls costs by requiring patients to choose approved doctors and hospitals. These doctors and hospitals have agreed to see HMO patients for reduced rates. In return, the doctors and hospitals receive a steady flow of patients sent by the HMO.

In addition, patients in many managed care programs must first see a primary care doctor for a referral to a specialist. Primary care doctors who control referrals to specialists are commonly called *gatekeepers.* HMO's also require both primary care doctors and specialists to seek approval for most treatments, and some treatments are not approved. The organizations usually set limits on the drugs doctors can prescribe and impose other restrictions. Many HMO plans cost less than fee-for-service plans and cover more types of care.

Another common managed care plan is called a *preferred provider organization* (PPO). A PPO is a loose network of doctors and hospitals who have agreed to care for PPO members at reduced rates. The doctors and hospitals who participate in the network are called *preferred providers.* Patients in a PPO can choose their doctors. But they must select one from among the preferred providers or pay a higher fee.

Many employers prefer to offer employees managed care insurance because it costs less than fee-for-service insurance. Both Medicare and Medicaid have begun experimenting with managed care to control costs. Some managed care patients also appreciate the lower costs and wider range of covered services. But other patients object to the limited choice imposed by such plans. In addition, many doctors are concerned about HMO review of their decisions and restrictions on treatment.

United States citizens pay directly—in other words, pay *out-of-pocket*—for much of the health care that they receive. Many insurance programs do not cover certain services, and many require patients to pay a portion of covered charges. A patient's portion of charges is called a *copayment.* In addition, the United States is the only developed country in which large numbers of people have no medical coverage of any kind. Part-time workers form one large group of uninsured citizens. Many employers do not offer health insurance to part-time employees because of its cost. Many of these workers earn too much to qualify for Medicaid. But they do not make enough to be able to afford a costly individual insurance policy. How to solve the problem of lack of insurance is a topic of active debate in the United States.

Other countries. Most industrialized countries have some type of comprehensive system that provides medical care for most citizens. Some nations pay for these systems with taxes. Others fund health insurance by requiring citizens to participate in national health insurance programs.

Developing countries face a particularly severe challenge in providing medical care. These nations struggle with serious shortages of money, medical facilities, and doctors and other health care workers. Neither the governments nor the citizens have the resources to pay for adequate levels of care. As in industrialized countries, life expectancy has increased. As people age, many fall ill with the age-related illnesses common elsewhere in the world—cancer, heart disease, and arthritis. In addi-

tion, many people, especially in Africa and Latin America, suffer from infections and parasites that are well controlled in richer countries.

Improving the quality of medical care

Two of the chief groups that work to improve the quality of care are (1) medical researchers and (2) medical organizations. In addition, computers and other technology enable medical professionals to learn about the latest approaches to medical care.

Medical researchers experiment and observe to gain new knowledge about health and disease. Discoveries made through research make important contributions to medical progress. Governments, major universities, private foundations, and drug companies provide funds to support research. Many medical researchers are physicians. Others have advanced degrees in biology, chemistry, or other sciences. Three main types of research include (1) basic laboratory research, (2) translational research, and (3) clinical research.

Basic laboratory research investigates fundamental biological questions. One extremely active area of basic research explores *genes* (the hereditary material in cells). Genes control all the life processes in living things, including how cells grow, divide, and communicate with other cells. Scientists worldwide are working to understand how genes function.

Knowledge gained through basic laboratory research may not apply immediately to medical practice. But basic researchers hope that their discoveries will lead eventually to improvements in treating or preventing disease.

Translational research aims at *translating* (transferring) discoveries from the laboratory to patient care. Translational research tries to find medical uses for knowledge gained through basic research. For example, basic researchers studying breast tissue might discover that many breast cancers have a particular abnormal gene. Translational research would then focus on finding ways that this discovery could help patients. Researchers might try to develop a blood test that would show whether people have the damaged gene. Identifying the damaged gene before individuals developed

Major medical specialty fields

Adolescent medicine deals with the special health care needs of teen-agers.
Allergy and immunology, *IHM yuh NAHL uh jee,* deals with disorders of the immune system, including allergies, autoimmune diseases, and immune deficiencies.
Anesthesiology, *AN uhs THEE zee AHL uh jee,* deals with the administration of anesthesia and anesthetics during operations or other procedures.
Cardiology, *KAHR dee AHL uh jee,* is the diagnosis and treatment of disorders of the heart or blood vessels.
Colon and rectal surgery is the surgical treatment of disorders of the lower digestive tract.
Dermatology diagnoses and treats diseases of the skin, nails, and hair.
Emergency medicine deals with the immediate diagnosis and treatment of acute injuries, illnesses, and emotional crises.
Family practice is the supervision of the total health care of patients and their families, regardless of age.
Internal medicine is the diagnosis and nonsurgical treatment of diseases of adults. There are several subspecialties of internal medicine.
Medical genetics deals with the genetic basis of disease.
Neurological surgery, also called *neurosurgery,* is the surgical treatment of disorders of the nervous system.
Nuclear medicine is the use of radioactive isotopes to diagnose and treat disease.
Obstetrics and gynecology, *ahb STEHT rihks, GY nuh KAHL uh jee,* provide the special medical care required by women. *Obstetricians* provide care for women during pregnancy and during and immediately after childbirth. *Gynecologists* diagnose and treat diseases of the female reproductive organs.
Oncology, *ahng KAHL uh jee,* deals with cancer. There are several subspecialties of oncology.
Ophthalmology, *AHF thal MAHL uh jee,* is the diagnosis, treatment, and prevention of eye diseases.
Orthopedics is the diagnosis and treatment of disorders of the skeletal and muscular systems.
Otolaryngology, *OH tuh LAR ihng GAHL uh jee,* diagnoses and treats ear, nose, and throat diseases.
Pathology, *puh THAHL uh jee,* is the study of changes in the body that cause disease or are caused by disease.
Pediatrics, *PEE dee AT rihks,* is the diagnosis, treatment, and prevention of children's diseases.
Physical medicine and rehabilitation, also called *physiatrics,* treats diseases and disabilities by such physical means as light, heat, and water therapy.
Plastic surgery restores or rebuilds certain parts of the body that are imperfect or have been damaged.
Preventive medicine deals with the relation between environment and health. Specialists may limit their practice to such fields as *public health* or *aviation medicine.*
Psychiatry and neurology deal with the mind and nervous system. *Psychiatrists* diagnose and treat mental disorders. *Neurologists* provide nonsurgical treatment of diseases of the nervous system.
Radiology is the use of X rays and radium to diagnose and treat disease.
Surgery treats diseases by operations. There are a number of surgical subspecialties.
Thoracic surgery, *thaw RAS ihk,* is the surgical treatment of diseases of the heart, lungs, or large blood vessels in the chest.
Urology, *yu RAHL uh jee,* deals with diseases of organs that pass urine and of the male reproductive organs.

cancer might lead to new ways to prevent the disease or treat its earliest stages.

Clinical research tests the safety and effectiveness of treatments in living organisms. Investigators conduct clinical research after preliminary research strongly indicates that a treatment may help patients. For example, basic research might identify a chemical that prevented cell division in tissue samples. Translational research would then try to develop a form of the chemical that could be used as a cancer drug. Cancer cells divide rapidly, and many cancer drugs work by interfering with this rapid multiplication. If a promising drug were developed, clinical researchers would conduct tests to ensure that the drug was safe. After its safety was established, more clinical research would determine if the new drug could actually help shrink tumors in cancer patients.

Medical organizations. Many national and international organizations work to improve the quality of medical care. National medical associations include the American Medical Association, the British Medical Association, and the Canadian Medical Association. Most national associations focus their efforts on education and professional development. They also represent medical interests before governments and other policy-making bodies. Many national associations participate in the World Medical Association. This international federation is dedicated to medical education, science, ethics, and health care for people worldwide.

One of the most prominent international associations is the World Health Organization (WHO), the health agency of the United Nations. WHO believes that health is a fundamental human right for all people. The agency operates many programs dedicated to obtaining the best possible health care for everyone, especially citizens of developing countries.

Medical organizations at all levels work to encourage professional development and the exchange of medical information. They publish journals that describe the latest research. They sponsor professional conferences where participants meet and share information. Organizations for individual medical specialties play a particularly strong role in providing information and professional support for their members. For example, the American College of Cardiology is a professional society for physicians and scientists who specialize in diseases of the heart and circulatory system.

Computers and electronic communication offer important ways to share information and advance medical knowledge. Like other scientists, doctors benefit tremendously from the Internet. The Internet is a vast worldwide computer network that connects governments, universities, businesses, and individuals. The Internet eliminates geographic barriers and makes information available in remote locations throughout the world. Many medical publications are available over the Internet. For example, computer users can electronically search and read thousands of medical journals in the U.S. National Library of Medicine.

The National Library of Medicine also makes available an electronic library of human anatomy on the Internet. This library, called the Visible Human Project, is a collection of thousands of images of two dead human bodies, one male and one female. The images were created using magnetic resonance imaging (MRI), computed tomography (CT), and extremely thin cross sections.

Doctors can also use the Internet to communicate and exchange information with one another. Electronic mail (e-mail) enables medical workers to send and receive messages instantly. X rays, lab results, and other aids in diagnosis can also be shared electronically. Some doctors even use e-mail to communicate with patients.

Careers in medicine

The profession of physician is perhaps the best-known medical career. Many other kinds of workers, however, help provide medical care.

A career as a doctor. Becoming a physician can provide a personally satisfying, highly respected career. In many developed countries, medicine is a well-paid profession. But becoming a doctor requires many years of challenging study in classrooms, in laboratories, and with patients. This section discusses physician training in the United States, Canada, and the United Kingdom.

In the United States, Canada, and the United Kingdom, doctors receive their professional education in medical school. In all three countries, most medical schools grant the doctor of medicine (M.D.) degree. In the United States and the United Kingdom, some schools grant the doctor of osteopathy (D.O.) degree. Osteopathy is a system of medical care founded in the late 1800's to emphasize the importance of the body's bones, muscles, ligaments, and tendons. Osteopathic medicine now includes all the treatments of modern medicine. D.O.'s are considered to have the same professional skills and responsibilities as M.D.'s.

In Canada and the United States, most students prepare for medical school by earning a college degree. The college work that comes before medical school is called *premedical training* or simply *premed.* Premedical training includes biology, chemistry, physics, and mathematics to equip students to understand the scientific and technical aspects of medicine. Most premed students also study languages, literature, history, and other subjects that help them understand human experience and appreciate patients as people. Doctors must be able to communicate clearly and kindly about complicated medical topics and matters of life and death.

Medical school in the United States and Canada lasts four years. In the United Kingdom, medical school begins directly after secondary school and lasts five years. In all three countries, students spend their first years in medical school studying sciences that form the foundation of medicine. These sciences include *biochemistry* (the chemistry of living things), *anatomy* (study of the body's structure), and *physiology* (the science of how cells, organs, and the body function). In later years of medical school, students receive their first *clinical training.* In clinical training, students learn by caring for patients under the supervision of experienced doctors.

After medical school, doctors-in-training enter advanced clinical programs to increase their skill and experience in treating patients. Students in the United Kingdom spend a sixth year after medical school gaining additional basic clinical skills before they enter advanced training. Depending on the medical field they want to enter, students may spend up to six or seven years in higher clinical training.

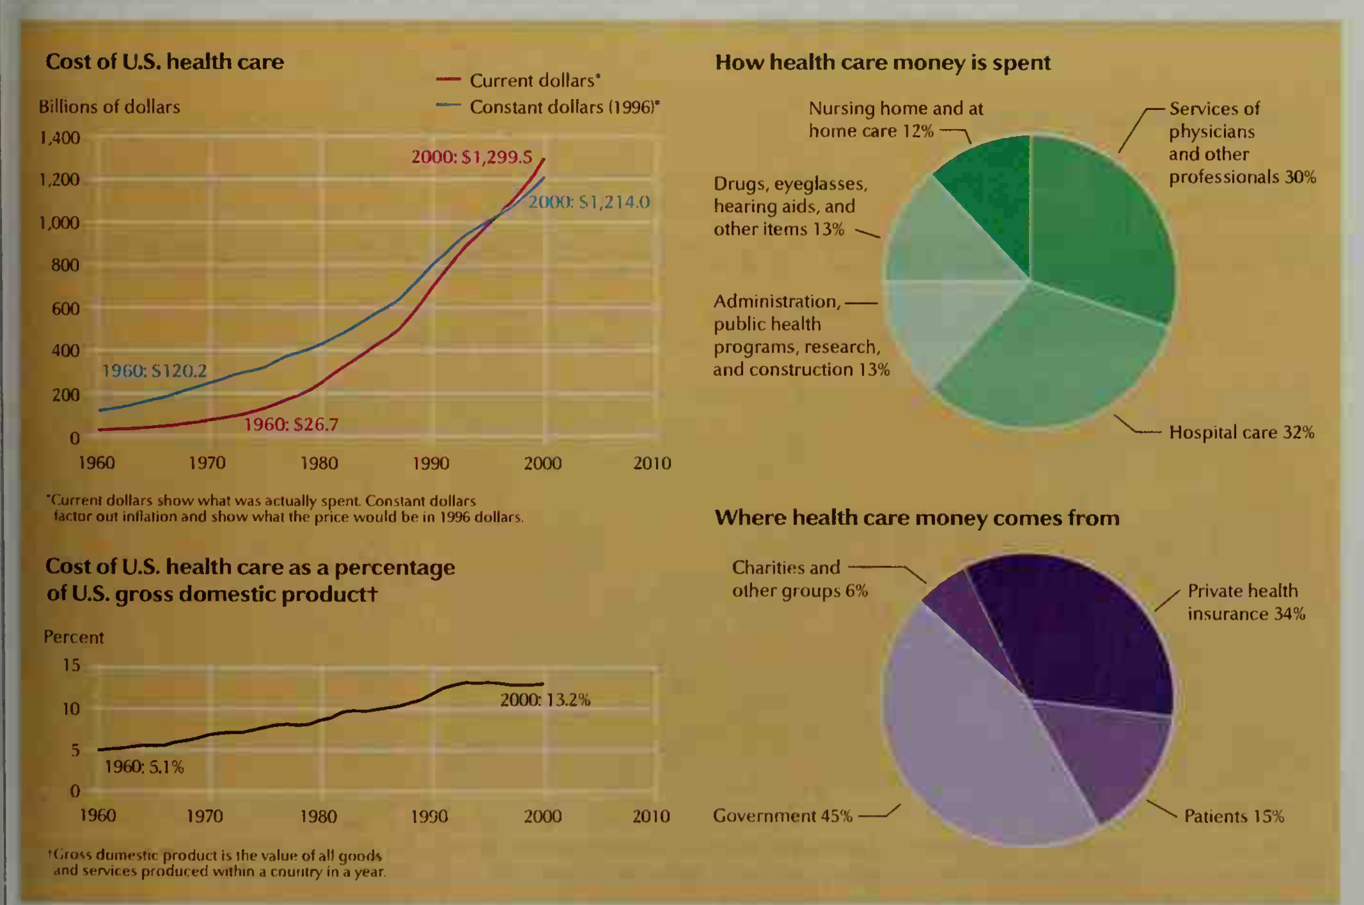
Doctors gain certification to practice medicine by passing national examinations that demonstrate their basic medical knowledge and skill in specialty areas. All the states of the United States and provinces of Canada grant licenses to practice medicine. In the United Kingdom, an agency called the General Medical Council admits qualified doctors to a national registry.

Other careers in medicine. Many people, in addition to physicians, play key roles in providing medical care. In many cases, successful care of patients depends on the efforts of a wide range of medical workers. See the articles on **Nursing** and **Pharmacy** for detailed information about these important medical occupations.

Physician assistants, also called PA's, are trained to provide basic medical care under the supervision of doctors. They take medical histories, perform routine examinations, order and interpret tests, and make a preliminary diagnosis. Many PA's work in primary care. Others assist in such specialties as surgery and emergency medicine. Physician assistants are not registered nurses. Most receive their training in a program that leads to a college degree. Others earn a degree in another field, then enter a physician assistant program after college.

Physical therapists and other specialty therapists. Several kinds of therapists provide specialized care or activities that form an important part of many treatment plans. *Physical therapists* use such physical means as light, heat, and exercise to improve patients' ability to move or function normally. *Occupational therapists* help people with illnesses or disabilities develop, recover, or maintain skills necessary for work or daily living. *Recreational therapists* guide patients in games, dance, arts and crafts, or other enjoyable activities to maintain physical and emotional well-being. *Respiratory therapists* provide evaluations and treatments for patients with breathing disorders.

Medical social workers help patients and their families cope with the social and emotional aspects of illness. They provide counseling and support and help patients arrange for care after leaving the hospital.



Technicians and technologists. A wide variety of medical occupations require high levels of particular technical skills. For example, *medical technologists* perform difficult and highly specialized laboratory tests. They also supervise *laboratory technicians,* who perform more routine laboratory tasks. *Radiologic technologists* prepare patients for X rays and other imaging procedures, such as ultrasound, computed tomography (CT), and magnetic resonance imaging (MRI). *Emergency medical technicians* (EMT's), also called *paramedics,* drive specially equipped vehicles to the scenes of emergencies. They administer urgent care, then transport patients to medical facilities.

History

In prehistoric times, people believed that angry gods or evil spirits caused disease. Curing the sick required calming the gods or driving the evil spirits from the

Expenditures for health care in the United States

The line graphs show how health care costs have risen since 1960. The pie charts show how health care money is spent and where it comes from.

Source: U.S. Department of Health and Human Services. Pie graph figures are for 2000.

body. The priests who tried to soothe the gods or drive out the evil spirits became the first professional healers of the sick.

The first known surgical treatment was an operation called *trephining* (pronounced *trih FY nihng).* Trephining involved using a stone instrument to cut a hole in a patient's skull. Scientists have found fossils of trephined skulls as much as 10,000 years old. Early people may have performed the operation to release spirits believed responsible for headaches, mental illness, or epilepsy. Trephining may actually have brought relief in some cases by releasing pressure in the head. Surgeons still use a similar procedure to relieve some types of pressure on the brain.

Prehistoric people probably also discovered that many plants can be used as drugs. For example, the use of willow bark to relieve pain likely dates back thousands of years. Today, scientists know that willow bark contains *salicin,* a substance related to the active ingredient in aspirin.

The ancient Middle East. By about 3000 B.C., the Egyptians, who had developed one of the world's first great civilizations, began making important medical progress. The world's first physician known by name was the Egyptian Imhotep, who lived about 2650 B.C. The Egyptians later worshiped him as the god of healing. About 2500 B.C., Egyptian surgeons produced a textbook that told how to treat dislocated or fractured bones and external abscesses, tumors, and wounds.

Other ancient Middle Eastern civilizations also contributed to medical progress. The ancient Israelites, for example, made advances in preventive medicine from about 1200 to 600 B.C. The Israelites required strict isolation of individuals with gonorrhea, leprosy, and other contagious diseases. They also prohibited the contamination of public wells and the eating of pork and other foods that might carry disease.

China and India. The ancient Chinese developed many medical practices that continue almost unchanged to the present day. Much of this traditional medicine is based on the belief that two principal forces of nature, called *yin* and *yang,* flow through the human body. Disease results when the two forces become out of balance. One technique that the Chinese developed to restore this balance was *acupuncture.* Practitioners of acupuncture insert needles into parts of the body thought to control the flow of yin and yang. Chinese doctors still practice acupuncture. The practice has gained popularity in Western countries, where it is used to treat nausea and some types of pain.

Traditional herbal cures and dietary practices in China also arouse interest today for their possible value in preventing disease. For example, breast cancer and colon cancer are rare in China and many other Asian countries. Many doctors think that one reason these cancers may be rare is that the typical Asian diet contains little fat.

In ancient India, the practice of medicine became known as *ayurveda.* It stressed prevention as well as the treatment of illness. By 600 to 500 B.C., practitioners of ayurveda had developed impressive knowledge of drugs to treat illness and of surgery. Indian surgeons successfully performed many kinds of operations, including amputations and a form of plastic surgery to reconstruct injured noses and ears.

Greece and Rome. The civilization of ancient Greece reached its height during the 400's B.C. During this peak, sick people seeking cures flocked to temples dedicated to Asclepius, the Greek god of healing. At the same

Highlights in medical history

- **c. 8000 B.C.** Prehistoric people practiced *trephining*—the first known surgical treatment.
- **c. 2500 B.C.** Egyptian physicians developed the first systematic methods of treating diseases.
- **400's B.C.** Hippocrates showed that diseases have only natural, not supernatural, causes.
- **A.D. 100's** Galen formulated the first medical theories based on scientific experimentations.
- **1100's** The first university medical schools developed in Europe.

International College of Surgeons Museum, Chicago (WORLD BOOK photo)

Trephining involved cutting a hole in the skull, perhaps to release evil spirits. The ancient trephined skull and cutting tools shown here were found in Peru.

Relief sculpture (A.D. 100's) by an unknown Greek sculptor; British Museum, London (Michael Holford)

Doctors in ancient Greece, such as the one shown here examining a young patient, developed the idea that disease has natural rather than supernatural causes.

Detail of a manuscript (about 1300); International College of Surgeons Museum, Chicago (WORLD BOOK photo)

During the Middle Ages, doctors had little scientific knowledge. This doctor is using all his strength to ineffectively bandage a broken jaw as tightly as possible.

time, the great Greek physician Hippocrates began showing that disease has natural rather than divine causes. He thus became the first known physician to consider medicine a science and art separate from the practice of religion. Hippocrates's high ideals are reflected in the Hippocratic oath, an expression of early medical ethics. But the oath was probably composed from a number of sources rather than written by Hippocrates himself. For the text of the oath, see the article **Hippocrates.**

After 300 B.C., the city of Rome gradually conquered Egypt, Greece, and much of the rest of the civilized world. The Romans borrowed most of their medical knowledge from Egypt and Greece. The Romans' own medical achievements occurred largely in public health. For example, they built large water channels called *aqueducts* to carry fresh water to Rome. They also built an excellent sewer system.

The Greek physician Galen, who practiced medicine in Rome during the A.D. 100's, made the most important contributions to medicine in Roman times. Galen performed experiments on animals and used his findings to develop the first medical theories based on scientific observations. He is considered the founder of experimental medicine. Galen wrote numerous books about medicine, anatomy, and physiology. As time passed, many of Galen's many theories were proved false. But some of his ideas continued to influence doctors into the 1500's.

During the Middle Ages, which lasted from the A.D. 400's to the 1500's, the Islamic empire of southwest and central Asia contributed greatly to medicine. Rhazes, a Persian-born physician of the late 800's and early 900's, wrote the first accurate descriptions of measles and smallpox. Avicenna, an Arab physician of the late 900's and early 1000's, produced a vast medical encyclopedia called *Canon of Medicine.* It summed up medical knowledge of the time and accurately described meningitis, tetanus, and many other diseases. The work became popular in Europe, where it influenced medical education for more than 600 years.

A series of epidemics swept across Europe during the Middle Ages. Outbreaks of leprosy began in the 500's and reached their peak in the 1200's. In the mid-1300's, a terrible outbreak of plague, now known as the Black Death, killed about one-fourth of Europe's people. Throughout the medieval period, smallpox and other diseases struck hundreds of thousands of people.

The chief medical advances in Europe during the Middle Ages were the founding of many hospitals and the first university medical schools. Christian religious groups established hundreds of charitable hospitals for people with leprosy. In the 900's, a medical school was established in Salerno, Italy. It became the main center of medical learning in Europe during the 1000's and 1100's. Other medical schools became part of newly developing universities during the 1100's and 1200's, such as the University of Bologna in Italy and the University of Paris in France.

The Renaissance. A new scientific spirit developed during the Renaissance, the great cultural movement that swept across Western Europe from about 1300 to the 1600's. Before the Renaissance, people thought the study of religion was the most important branch of learning. During the Renaissance, the study of medicine and other sciences, art, literature, and history gained new significance. Before this time, most societies had strictly limited the practice of *dissecting* (cutting up) human corpses for scientific study. But laws against dissec-

1543 Vesalius published the first scientific study of human anatomy.

Mid-1500's Paré, the "father of modern surgery," introduced advanced surgical techniques.

1628 Harvey started modern physiology with his book on blood circulation.

1670's Leeuwenhoek discovered bacteria, which helped lead to the germ theory of disease.

1796 Jenner gave the first officially recognized vaccination, against smallpox.

International College of Surgeons Museum, Chicago (WORLD BOOK photo)

Scientific study of anatomy began with Andreas Vesalius's book *On the Structure of the Human Body.* This drawing from the book shows spinal nerves.

Wood engraving (1594) by an unknown artist (Corbis-Bettmann)

Surgical advances by Ambroise Paré in the 1500's included sewing through pieces of cloth glued to the patient's skin instead of stitching through the skin itself.

Detail of an engraving after a painting (late 1800's?) by Georges Gaston; Théodore Mélingue (Granger Collection)

Edward Jenner vaccinates a child. Jenner's discovery of a smallpox vaccine in 1796 led to the development of vaccines to prevent many other diseases as well.

tion were relaxed during the Renaissance. As a result, the first truly scientific studies of the human body began.

During the late 1400's and early 1500's, Italian artist Leonardo da Vinci performed many dissections to learn about human anatomy. He recorded his observations in a series of more than 750 drawings. Andreas Vesalius, a physician and professor of medicine at the University of Padua in Italy, also performed numerous dissections. Vesalius used his findings to write the first scientific textbook on human anatomy, a work called *On the Structure of the Human Body* (1543). This book gradually replaced the texts of Galen and Avicenna.

Other physicians also made outstanding contributions to medical science in the 1500's. A French army doctor named Ambroise Paré is considered the father of modern surgery for his improvements in surgical technique. For example, Paré opposed the common practice of *cauterizing* (burning) wounds with boiling oil to prevent infection. Instead, he developed the much more effective method of applying a mild ointment and then allowing the wound to heal naturally. Philippus Paracelsus, a Swiss physician, stressed the importance of chemistry in the preparation of drugs. He pointed out that in many drugs, one ingredient canceled the effect of another.

The beginnings of modern research. English physician William Harvey performed many experiments in the early 1600's to learn how blood circulates through the body. Before Harvey, Galen and other scientists had studied circulation. But they had observed only parts of the process and invented theories to fill the gaps in their observations. Harvey studied the entire process. He observed the human pulse and heartbeat and performed dissections on human beings and other animals. Harvey concluded that the heart pumps blood through the arteries to all parts of the body. He further realized that the blood returns to the heart through the veins.

Harvey described his findings in *An Anatomical Study of the Motion of the Heart and of the Blood in Animals* (1628). His discovery of how blood circulates marked a turning point in medical history. After Harvey, scientists realized that understanding how the body works depends on knowledge of the body's structure.

In the mid-1600's, an amateur Dutch scientist named Anton van Leeuwenhoek *(LAY vuhn hook)* saw tiny objects moving under his microscopes. He concluded correctly that these tiny objects were actually animals invisible to the naked eye. Today, such organisms are called *microorganisms.* They are also known as *microbes* or *germs.* Leeuwenhoek did not understand the role of microbes in nature. But his research led to later discoveries that certain microbes cause disease.

The development of immunology. *Immunology* is the study of the body's ability to resist disease. Developing ways to increase the body's natural resistance has become one of the most important areas of modern medicine. A milestone in immunology occurred in the prevention of smallpox, one of the most feared and highly contagious diseases of the 1700's. Smallpox killed many people and scarred others for life.

Doctors had known for hundreds of years that a person who recovered from smallpox developed lifelong *immunity* (resistance) to it. To provide this immunity, doctors sometimes inoculated people with matter from a smallpox sore. The doctors hoped that the inoculation would cause only a mild case. But some people developed a severe case of smallpox instead of a mild one. Other inoculated persons spread the disease.

In 1796, English physician Edward Jenner discovered a

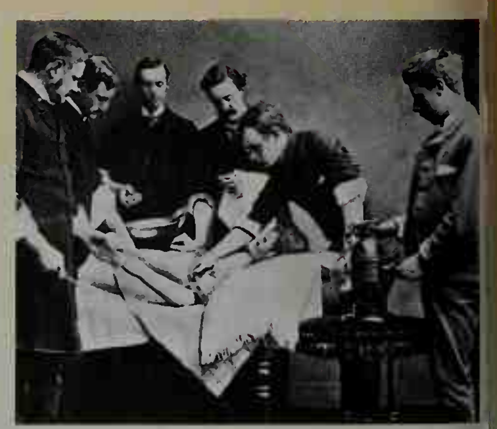
1842-1846 — Long and Morton introduced the use of ether, the first practical anesthetic.

Mid-1800's — Nightingale founded the modern nursing profession.

1850's — Virchow pioneered in *pathology,* the scientific study of disease.

Mid- to late 1800's — Pasteur and Koch proved that certain bacteria cause certain diseases.

1865 — Lister introduced antiseptic methods to surgery.



Detail of a mural (1893) by Robert Hinckley; Boston Medical Library

Ether anesthesia was first demonstrated publicly at Massachusetts General Hospital in 1846. William Morton, shown holding the flask, administered the drug.

Detail of a pencil drawing (1847) by George Scharf (Granger Collection)

Florence Nightingale introduced modern nursing methods while caring for wounded soldiers during the Crimean War (1853-1856).

Detail of photograph taken about 1870 in Edinburgh, Scotland; Corbis-Bettmann

The first antiseptic surgery involved spraying surgical wounds with carbolic acid to prevent infection. Joseph Lister developed this procedure in 1865.

safe method of making people immune to smallpox. He inoculated a young boy with matter from a cowpox sore. The boy developed cowpox, a relatively harmless disease related to smallpox. But when Jenner later injected the boy with matter from a smallpox sore, the boy did not come down with that disease. His bout with cowpox had helped his body build up an immunity to smallpox. Jenner's classic experiment was the first officially recorded vaccination.

The first anesthetic. For thousands of years, physicians tried to dull pain during surgery by administering alcoholic drinks, opium, and various other drugs. But no drug had proved really effective in reducing the pain and shock of operations. Then in the 1840's, two Americans—Crawford Long and William T. G. Morton—discovered that ether gas could safely put patients to sleep during surgery. Long, a physician, and Morton, a dentist, appear to have made the discovery independently. With an anesthetic, doctors could perform many operations that they could not attempt on conscious patients.

Scientific study of the effects of disease, called *pathology,* developed during the 1800's. Rudolf Virchow, a German physician and scientist, led the field. Virchow believed that understanding a disease required understanding its effects on body cells. Virchow did important research in leukemia, tuberculosis, and other illnesses. Development of greatly improved microscopes in the early 1800's made his studies possible.

Scientists of the 1800's made dramatic progress in learning the causes of infectious disease. As early as the 1500's, scholars had suggested that tiny invisible "seeds" caused some diseases. The microbes discovered by Leeuwenhoek in the 1600's fit this description. In the late 1800's, the research of Louis Pasteur and Robert Koch firmly established the idea called the *microbial theory* of disease. This idea is also called the *germ theory.*

Pasteur, a French chemist, proved that microbes are living organisms and that certain microbes cause disease. He also proved that killing specific microbes stops the spread of specific diseases. Koch, a German physician, invented a method for determining which bacteria cause particular diseases. This method enabled him to identify the bacterium that causes *anthrax,* a severe disease of people and animals. Anthrax bacteria became the first germs definitely linked to a particular disease. Koch also discovered the cause of tuberculosis.

Other research scientists followed the lead of these two pioneers. By the end of the 1800's, researchers had discovered the kinds of bacteria and other microbes responsible for many infectious diseases. These illnesses included plague, cholera, diphtheria, dysentery, gonorrhea, leprosy, malaria, pneumonia, and tetanus.

Antiseptic surgery. Hospitals paid little attention to cleanliness before the mid-1800's. Operating rooms were often dirty, and surgeons operated in street clothes. Up to half of all surgical patients died of infections. In 1847, a Hungarian doctor, Ignaz Semmelweis, stressed the need for cleanliness in childbirth. But Semmelweis knew little about the germ theory of disease.

Pasteur's early work on bacteria convinced an English surgeon named Joseph Lister that germs caused many deaths of surgical patients. In 1865, Lister began using carbolic acid, a powerful disinfectant, to sterilize surgical wounds. But this method was later replaced by a more efficient technique known as *aseptic surgery.* This technique involved keeping germs away from surgical wounds in the first place instead of trying to kill germs already there. Surgeons began to wash thoroughly be-

1895 — Roentgen discovered X rays, used in diagnosing diseases and treating cancer.

1898 — The Curies discovered radium, used in treating cancer.

c. 1900 — Freud developed the psychoanalytic method of treating mental illness.

Early 1900's — Eijkman and Hopkins demonstrated the existence of vitamins.

Detail of sketch by Robert Koch (1876); Aldus Archives

Anthrax germs were the first microorganisms identified as a cause of illness. Robert Koch made the discovery and did this sketch of the microbes.

Wellcome Historical Medical Museum, London

Marie and Pierre Curie, the discoverers of radium, are shown at work in their laboratory. Until the mid-1950's, radium was widely used for treating cancer.

fore an operation and to wear sterilized surgical gowns, gloves, and masks.

Professional organizations and medical reform. During the 1800's and early 1900's, doctors founded groups in the United States, Canada, and the United Kingdom to organize and reform the medical profession. In 1847, U.S. doctors founded the American Medical Association to help raise the nation's medical standards. Partly as a result of the AMA's efforts, the first state licensing boards were set up in the late 1800's. The British Medical Association was founded in 1855, and the Canadian Medical Association in 1867. The National Medical Association was started in 1895 by African American doctors who felt discriminated against by the AMA. Osteopathic physicians founded the American Osteopathic Association in 1897.

In 1910, the Carnegie Foundation for the Advancement of Teaching issued a report called *Medical Education in the United States and Canada.* American educator Abraham Flexner wrote the report, which he based on detailed evaluations of all 155 medical schools in the two countries. The study, known informally as the Flexner Report, found that many schools failed to prepare students for the rapidly developing age of scientific medicine.

Flexner recommended improving the quality of medical schools by requiring entering students to have college-level preparation in basic sciences and humanities. He further urged that medical schools should provide advanced scientific study, well-equipped laboratories, and broad clinical experience with patients. Finally, medical schools should have strong relationships with universities and teaching hospitals. Flexner's report helped bring far-reaching reforms to medical schools in the United States and Canada.

The medical revolution. Advances in many fields of science and engineering created a medical revolution that began around 1900. German physicist Wilhelm Roentgen discovered X rays in 1895. X rays became the first of many technologies that enable doctors to "see" inside the human body to diagnose illnesses and injuries. Discovery of radium by the French physicists Pierre and Marie Curie in 1898 eventually provided a powerful weapon against cancer.

In the early 1900's, Christiaan Eijkman of the Netherlands, Sir Frederick Hopkins of England, and a number of other physician-scientists showed the importance of vitamins. Their achievements helped conquer such nutritional diseases as beriberi, rickets, and scurvy. About 1910, the German physician and chemist Paul Ehrlich introduced a method of treatment called *chemotherapy.* Chemotherapy administers chemicals that have a more toxic effect on diseased cells than on healthy ones.

Ehrlich's work greatly advanced drug research. In 1935, German doctor Gerhard Domagk discovered that a type of dye could cure infections in animals. His discovery led to development of bacteria-fighting compounds called *sulfa drugs* to treat diseases in human beings. In 1928, English bacteriologist Sir Alexander Fleming discovered the germ-killing power of a mold called *Penicillium.* In the early 1940's, a group of English scientists headed by Howard Florey isolated penicillin, a product of this mold. Penicillin thus became the first antibiotic.

Since Domagk and Fleming made their historic discoveries, scientists have developed hundreds of antibiotics. These drugs have helped control the bacteria that cause many serious infectious diseases. Other drugs have been developed to treat such disorders as diabetes, high blood pressure, arthritis, heart disease, and cancer.

- **1928** Fleming discovered penicillin, the first antibiotic drug.
- **Early 1950's** Salk developed the first successful polio vaccine.
- **1954** American surgeons transplanted a kidney—the first successful organ transplant.
- **Early 1970's** A British engineer developed the first computed tomography (CT) scanner.
- **1980** The World Health Organization (WHO) announced that smallpox had been eliminated.
- **1990** The Human Genome Project, an international effort to analyze all human genes, began.

Abbott Laboratories

National Library of Medicine

The Visible Human Project is an electronic library of anatomy. The U.S. National Library of Medicine sponsored creation of the images in the mid-1990's.

The development of new vaccines has helped control the spread of polio, hepatitis, measles, and other infectious diseases. During the 1960's and 1970's, the World Health Organization conducted a vaccination program that eliminated smallpox from the world.

During the 1980's and 1990's, scientists began to make significant progress in understanding *genes* (the hereditary material in cells). Researchers successfully identified the genetic defects involved in some diseases. The first tests were developed to enable doctors to determine if individual patients have a damaged gene in all their body cells. Doctors are hopeful that understanding genes will lead to new ways to treat or prevent disease.

Much progress in modern medicine has resulted from engineering advances. Engineers have developed a variety of instruments and devices to aid doctors in the diagnosis, treatment, and prevention of diseases (see **Biomedical engineering**). In many cases, doctors can now perform microsurgery through tiny incisions using small precision instruments. This technique reduces the trauma of surgery and shortens or avoids hospitalization. See **Surgery** (Technique). Engineers have made great progress in creating highly advanced replacements for worn or damaged body parts. These replacements include artificial limbs, joints, and heart valves. Imaging techniques, such as MRI, CT, and positron emission tomography (PET), produce amazingly detailed views of internal body structures.

The Nobel Prizes, first awarded in 1901, recognize important medical achievements with a prize for physiology or medicine. The table in the **Nobel Prize** article lists the scientists who have received the physiology or medicine prize and describes each achievement that earned the honor.

Current issues in medicine

Major issues in medicine today include the distribution of medical care, the financing of advanced medical care, and the growing role of genetics in medicine.

Unequal distribution of medical care. The level of medical care varies tremendously throughout the world. In the richest countries, many people receive the most advanced treatment available. In poorer nations, citizens may lack even basic care. Many people are troubled that medical care can differ according to where people live and how much money they have. These people agree with the World Health Organization that medical care is a basic human right. But no one has found a way to pay for medical care for all of the world's citizens.

Treatment of AIDS serves as a good example of how sharply medical care can vary from one country to another. In the United States and other developed countries, preventing and treating AIDS has become a major medical focus. Educational programs alert people about the danger of AIDS. These programs explain how to avoid infection by using *condoms* (a type of birth control) and taking other steps. Scientists have developed drugs that dramatically lower the amount of HIV, the virus that causes AIDS, in the body. Other drugs greatly decrease the risk that mothers will transmit HIV to their newborns during birth. Governments, private foundations, universities, and drug companies spend huge amounts of money to find even better methods of prevention and treatment.

In the poor countries of Africa, however, AIDS remains an unchecked epidemic. There is little money to educate people about avoiding AIDS, and many people cannot afford condoms. Poor African countries have difficulty paying for AIDS drugs, which can cost thousands of dollars per year for each patient. There is no money for research.

Availability of doctors and medical facilities is another area in which rich and poor countries differ greatly. In many rich countries, experts believe that there is an oversupply of doctors and that too many of them are specialists. By contrast, many poor countries have a serious shortage of doctors of any kind.

Financing advanced medical care. In developed countries, doctors, citizens, insurers, and policymakers struggle to continue funding high levels of health care. Canada, the United Kingdom, and other countries with national health care try to maintain the quality of their systems and keep them fair. People are growing older and developing age-related ailments that are expensive to treat. At the same time, researchers are gaining new insights into genes and other basic biological processes. These insights may lead to treatments that are more effective but cost even more than current care. Experts are debating how national health systems can continue to pay for advanced health care for everyone.

The United States faces particularly difficult health care choices. Because there is no national U.S. health

system, different groups of citizens already receive different levels of care. American policy experts are debating ways to eliminate health care gaps among citizens or keep the gaps from widening.

Private insurance is the most common U.S. health care plan and thus controls huge amounts of health care money. Because of its importance, private insurance heavily influences U.S. health care policy. Many insurance companies and managed care plans operate as businesses. Their chief goal is to make money for their owners and investors, who may not be doctors or medical workers. Some people wonder if such business principles as competition and profit making now play too large a role in U.S. medicine.

Education of doctors is one area in which business principles have a growing influence. Because many insurance plans control costs by emphasizing primary care, there is reduced need for medical specialists. Many specialty training programs have been cut back, merged with similar programs, or eliminated.

Increased focus on saving money also affects how hospitals pay for educating doctors. Hospitals in which doctors receive their higher clinical training are called *teaching hospitals.* These hospitals traditionally made up for the cost of training doctors by charging more for care than did hospitals without training responsibilities. Insurance plans paid the higher fees because such hospitals provided the most advanced care available. But many managed care systems are unwilling to pay teaching hospitals' higher fees. Many experts worry about the effect that this refusal will have on doctor training.

Another factor affecting the cost of U.S. health care is malpractice. American patients are among the most likely in the world to sue their doctors or hospitals. Most people agree that patients need protection against negligent health care. But most experts feel that the high likelihood of malpractice suits drives up the cost of medical care. Doctors and hospitals must buy expensive malpractice insurance, and the cost is passed along to patients as higher fees. Experts are debating ways to reduce the effect of malpractice on medical costs.

Managed care further complicates malpractice. Managed care systems conduct reviews of doctors' treatment plans, and the system may refuse to approve treatment. In many cases, however, the individual doctor rather than the managed care organization remains legally responsible for the treatment decision.

The challenge of genetics. During the 1980's and 1990's, knowledge about genes and how they work began to play an important role in medicine. Scientists identified particular genes that increase risk of many diseases, including breast cancer, colon cancer, and certain brain disorders. In 2001, the Human Genome Project, an international scientific effort, and a private company called Celera Genomics Corporation announced that together they had essentially identified all genes in the human genome. Scientists hope to use this information to determine how genes in the human body function in health and disease.

The age of genetic medicine holds great promise for new ways of preventing and treating illness. But genetic medicine also creates many challenges for doctors, patients, and societies. Identifying an abnormal gene alerts doctors and patients to watch closely for signs of the disease associated with that gene. But in most cases, testing offers little other medical benefit because few treatments yet exist for damaged genes. As a result, doctors are uncertain about when genetic tests should be used and who should be tested.

Many patients question whether the benefits of knowing their genetic flaws are sufficient to outweigh the anxiety this knowledge will bring. In addition, patients worry about their ability to keep information about their genetic abnormalities private. Policymakers share these fears. They worry that insurers may not want to provide insurance for people with genetic abnormalities. Another concern is that employers may try to avoid hiring these people. Societies must try to find ways to protect people from misuse of genetic information. At the same time, they want to encourage continued progress in this important new area of human knowledge.

Outline

I. Elements of medical care
A. Prevention
B. Diagnosis
C. Treatment
II. Medical professionals
A. Specialty care physicians
B. Primary care physicians
C. Other health care professionals
III. Providing medical care
A. The United Kingdom
B. Canada
C. The United States
D. Other countries
IV. Improving the quality of medical care
A. Medical researchers
B. Medical organizations
C. Computers and electronic communication
V. Careers in medicine
A. A career as a doctor
B. Other careers in medicine
VI. History
VII. Current issues in medicine
A. Unequal distribution of medical care
B. Financing advanced medical care
C. The challenge of genetics

Questions

Why is medicine both a science and an art?
What is primary care? Who provides it?
What are the three main elements of medical care?
Who proved that certain microbes cause disease?
What are *physician assistants? Medical technologists?*
How do computers help improve medical care?
What subjects do U.S. and Canadian doctors-in-training study during their *premedical education?*
What is the World Health Organization? What does it do?
Who was the first physician known to consider medicine a science and art separate from religion?

Medill, *muh DIHL,* **Joseph** (1823-1899), a crusading American editor and publisher, made the *Chicago Tribune* one of the world's most successful newspapers. He served as managing editor from 1855 to 1863, as editor in chief from 1863 to 1866, and as publisher from 1874 until his death. Many of his editorials concerned government reforms. Medill worked hard to build the Republican Party. Some authorities believe he named the party. He helped sponsor Abraham Lincoln as a candidate for the presidency. Medill served at the Illinois Constitutional Convention of 1869, on the Civil Service Commission under President Ulysses S. Grant, and as mayor of Chicago from 1872 to 1874. He was born on April 6, 1823, near Saint John, New Brunswick, Canada. Robert K. Stewart
Medina, *muh DEE nuh* (pop. 608,295), is a city in western Saudi Arabia. It lies on a fertile plain about 200 miles (320 kilometers) north of Mecca (see **Saudi Arabia** [political map]). Medina and Mecca are the holiest cities in Islam, the Muslim religion, and only Muslims may enter them. The Holy Mosque of the Islamic prophet Muhammad is in Medina. This mosque holds Muhammad's tomb. Islam requires every Muslim to make at least one pilgrimage to Mecca if possible. Most pilgrims who visit Mecca also go to Medina.

Farmers grow fruits and vegetables in the area around Medina. Agriculture and money spent by pilgrims form the basis of Medina's economy. The city is the home of the Islamic University. Medina has kept much of its traditional appearance. As Medina has grown, however, the walls of the old city have disappeared. New suburbs have grown up, and wealthy residents live in these areas.

No one knows when Medina was founded. It was originally called *Yathrib,* and farmers settled there before 200 B.C. Medina received its present name, which means *town* or *city,* in the early 600's. Muhammad and his disciples found safety in Medina after they were forced to flee from Mecca in 622. Medina became the center of the Muslim community, but its political importance fell as the Islamic empire grew. Malcolm C. Peck

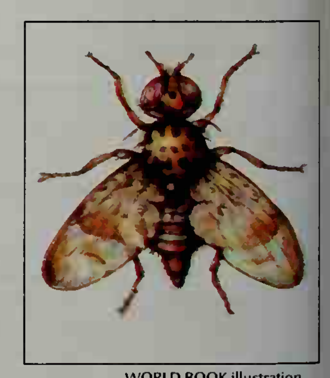
See also **Muhammad** (His teachings; The Hijra).
Medina, *muh DEE nuh,* **Harold Raymond** (1888-1990), an American judge, won international fame for his fair conduct of the trial of 11 American Communist Party leaders in 1949. These leaders were convicted of conspiring to teach and advocate the overthrow of the U.S. government by force. Medina urged the jury to be calm and cautioned that "justice does not flourish amidst emotional excitement and stress."

Medina was born on Feb. 16, 1888, in Brooklyn, New York. He graduated from Princeton University. He received his law degree from Columbia University in 1912 and taught there from 1915 to 1947. He practiced law in New York City until he was appointed a federal judge in 1947. He retired from that post in 1958. David M. O'Brien
Meditation is the act of thinking deeply and at length. Most meditation consists of exercises intended to create a state of peace and relaxation, heightened awareness or spiritual purification. Much meditation is part of religious practice, and most major religions have systems of meditation.

In some religions, the individual meditates through the repetition of a specific sound, word, or text. For example, Hindus and Buddhists meditate by repeating a sound or verse called a *mantra.* Mantra texts may be enclosed in a metal cylinder called a *prayer wheel.* Each turn of the wheel symbolically releases a mantra.

Some meditation involves focusing on a certain visual image. In Tantric Buddhism, the individual concentrates on a sacred diagram of the universe called a *mandala.*

Objects or physical actions may enhance meditation. Roman Catholics may meditate while reciting and counting prayers on a string of beads called a *rosary.* A Hindu system of meditation called *yoga* involves special sitting positions breath control and other physical disciplines.



Meditation resembles a spiritual activity called *contemplation.* However, contemplation seeks a mystical experience rather than relaxation or awareness. Jill Raitt

Mediterranean fruit fly is an insect that destroys fruits, nuts, and vegetables. It attacks more than 200 kinds of plants, especially tropical species.

Scientists believe that the Mediterranean fruit fly, popularly called the *Medfly,* originated in tropical west Africa. Long ago it made its way to northern and southern Africa, southern Europe, and Asia. It had spread throughout the Mediterranean region by 1850. The fly was found in Australia in the late 1800's, and it appeared in Brazil and Hawaii in the early 1900's.

In 1929, the Medfly was discovered in Florida. A quarantine was quickly ordered in the infested area to prevent the fly from spreading. By mid-1930, all of these flies in the United States had apparently been destroyed. Since that time, several other invasions of the fly in California, Florida, and Texas have also been stopped.

The Medfly is slightly smaller than a common housefly. Its wings have yellowish-orange spots. The female fruit fly can lay as many as 1,000 eggs in her lifetime and up to 40 per day. She typically lays eggs in a ripe fruit that is still on the tree. She drills tiny holes into the skin or rind of the fruit, and lays from two to six eggs in each hole. The eggs hatch into larvae, which eat their way through the fruit, causing it to drop to the ground. The larvae later burrow into the ground for the *pupal stage* of development. They come out of the ground as adult Medflies.

WORLD BOOK illustration by Oxford Illustrators Limited
Mediterranean fruit fly

The Mediterranean fruit fly thrives in a warm climate. Extremely hot or cold weather can kill it. There are also several insect parasites that destroy the larvae and pupae of the Medfly. These parasites can help control the fly, but they cannot eliminate it. A person who suspects that fruit is infested with Medfly larvae should have the fruit examined by an expert. Donald L. Dahlsten
Mediterranean Sea, *MEHD uh tuh RAY nee uhn,* has been one of the world's chief trade routes since ancient times. Many early civilizations, such as those of Egypt,

Greece, Phoenicia, and Rome, developed along its shores. Today, the sea's islands and coastal areas rank among the world's most popular tourist attractions.

Location and size. The Latin word *mediterranean* means *in the middle of land,* and land almost surrounds the Mediterranean Sea. Europe lies to the north, Asia to the east, and Africa to the south.

On the west, the Strait of Gibraltar connects the Mediterranean with the Atlantic Ocean. Another strait, the Dardanelles, links the Mediterranean on the east with the Sea of Marmara, the Bosporus, and the Black Sea. On the southeast, the Isthmus of Suez separates the Mediterranean and Red seas. The Suez Canal, an artificial waterway, crosses this thin strip of land.

The Mediterranean covers about 969,100 square miles (2,510,000 square kilometers). The Black Sea, which many people consider part of the Mediterranean, has an area of about 173,000 square miles (448,000 square kilometers). Several other arms of the Mediterranean are large enough to be called seas. They include the Adriatic, Aegean, Ionian, and Tyrrhenian seas.

Excluding the Black Sea, the Mediterranean is more than twice as long as it is wide. It has a maximum length of about 2,200 miles (3,540 kilometers), between the Strait of Gibraltar and Iskenderun, Turkey. The widest part of the sea lies between Libya and Croatia, a distance of about 1,000 miles (1,600 kilometers).

The seabed. An underwater ridge between Sicily and Tunisia divides the Mediterranean into two basins. The eastern basin is deeper than the western one. The sea has an average depth of 4,926 feet (1,501 meters). It reaches its greatest depth—16,302 feet (5,093 meters)—in a depression called the Hellenic Trough that lies between Greece and Italy.

Earthquakes occur frequently throughout the Mediterranean region, especially in Greece and western Turkey. Volcanic action formed many of the islands in the Mediterranean Sea. A few volcanoes still erupt in the area, such as Mount Etna, Stromboli, and Vesuvius.

Earth scientists explain the earthquakes and volcanic activity by the theory of *plate tectonics.* According to this theory, the earth's outer shell consists of about 30 rigid plates that are in slow, continuous motion. Movements of plates that carry the European and African continents and the Mediterranean seabed squeeze and stretch the earth's crust in the Mediterranean region, causing earthquakes and volcanoes.

Coastline and islands. Many bays and inlets indent the coastline of the Mediterranean. Several large peninsulas, including Italy and the Balkan Peninsula, jut out into the sea. Along most of the coast, rugged hills rise sharply from the water. Egypt and Libya have flatter coastal areas, with plains lying next to the sea.

Sicily, the largest island in the Mediterranean, covers 9,926 square miles (25,708 square kilometers). Other large islands include, in order of size, Sardinia, Cyprus, Corsica, and Crete.

Climate. The temperature at the surface of the Mediterranean averages about 61 °F (16 °C). In summer, the temperature may reach 80 °F (27 °C). It seldom drops below 40 °F (4 °C). The water varies little in temperature in the middle depths and near the bottom. It stays between 54 ° and 59 °F (12 ° and 15 °C) throughout the year.

The tremendous volume of warm water helps give the land surrounding it a warm, subtropical climate. Most Mediterranean countries have hot, dry summers and mild, rainy winters. These conditions provide what has become known as a "Mediterranean climate," even when they occur elsewhere. Two Mediterranean countries, Egypt and Libya, have tropical climates, hotter and dryer than the typical Mediterranean type.

A hot wind known as the *sirocco* blows across the

Mediterranean from Africa toward southern Europe. A cold, dry wind called the *mistral* blows the other way, from France out over the sea. See **Sirocco**.

The water of the Mediterranean comes mostly from the Atlantic Ocean and the Black Sea and from rainfall. Several large rivers also empty into the Mediterranean. The largest include the Ebro of Spain, the Nile of Egypt, the Po of Italy, and the Rhône of France.

The warm, dry climate gives the sea a high rate of evaporation. As a result, the water of the Mediterranean is saltier than that of the Atlantic.

Most parts of the Mediterranean have a *semidiurnal* tide—that is, it has two high tides and two low tides about every 24 hours. But the average difference between a high tide and a low tide in the Mediterranean is only about 1 foot (0.3 meters). A strong current flows into the Mediterranean from the Black Sea. Another flows in from the Atlantic through the Strait of Gibraltar. Beneath the surface current, a deeper current of dense salty water flows from the Mediterranean to the Atlantic.

Economic importance. The warm climate, beautiful scenery, and historical importance of the Mediterranean region attract millions of tourists yearly. Popular resort areas include the Greek islands and the French and Italian rivieras. The Mediterranean has little large-scale commercial fishing, but it is an important source of food for the people of the region. The chief seafoods include anchovies, sardines, shrimp, and tuna. Other products harvested from the sea include coral and sponges. The Mediterranean serves as an important waterway that links Europe, the Middle East, and Asia. Ships use the Suez Canal as a route between the Mediterranean and Red seas. Deposits of petroleum and natural gas have been discovered in the seabed beneath the Mediterranean. But most of these resources remain unused.

Formation of the sea can be explained by the theory of plate tectonics. About 250 million years ago, the continents formed a single land mass called Pangaea. The Tethys Sea, a huge bay that developed into the Mediterranean, indented the east coast of Pangaea. Through the centuries, Pangaea broke up into continents that began to drift slowly toward their present location. As they drifted, Africa turned counterclockwise, and Eurasia turned clockwise. Their movement opened a waterway at the western end of the sea, linking it with the ocean. By about 65 million years ago, the rotation of these two continents had almost closed the eastern end of the Tethys Sea. The sea thus acquired its present shape.

Some earth scientists believe the sea dried up about a dozen times between 7 $\frac{1}{2}$ million and 5 $\frac{1}{2}$ million years ago. During this period, the movement of the European and African continents repeatedly closed and reopened the Strait of Gibraltar. Each time the strait closed, the Mediterranean began to dry up. Also, glaciers may have lowered the Atlantic Ocean's water level, helping to prevent Atlantic water from passing through the strait to the Mediterranean. After about 1,000 years of drying up, only a large desert remained. A few salty lakes dotted this desert. When the strait reopened, water from the Atlantic rushed in, forming a huge waterfall. The waterfall refilled the Mediterranean in about 100 years.

In 1970, scientists found evidence that supported the desert theory. That year, geologists aboard a research vessel called the *Glomar Challenger* drilled cores of rock from the Mediterranean floor. The cores contained deposits of salt and other minerals, known as *evaporites,* that are formed by the evaporation of salty water. However, some researchers now believe the deposits could have resulted from a drastic lowering of the Mediterranean's water level without it completely drying up.

History of the Mediterranean. Many historians believe Western civilization was born in the Mediterranean region. Ancient cultures grew up on the banks of the sea, where conditions favored their development. The mild climate encouraged human settlement. The sea's calm waters and steady winds most of the year made seafaring relatively easy. The sea also had natural harbors and many islands that sailors could use as ports.

Probably the first great civilization to develop in the Mediterranean region was that of ancient Egypt. The Egyptians had a unified national government by about 3100 B.C. and had begun using a writing system by 3000 B.C. The first important European civilization, the Minoan culture, arose on the island of Crete about 3000 B.C. Another culture, the Helladic civilization, grew up on the Greek mainland. One city, Mycenae, became so powerful that some historians call the later Helladic civilization *Mycenaean.* By about 1450 B.C., Mycenaean ships controlled the Mediterranean. They traded with cities as far away as what are now Lebanon and Syria.

After about 1200 B.C., the Phoenicians began to win control of the Mediterranean. From their homes on the eastern shore, they sailed to all parts of the sea. Phoenician sailors even traveled through the Strait of Gibraltar into the Atlantic. Carthage, a colony founded by the Phoenicians, became another great sea power after about 600 B.C. By the A.D. 100's, the Roman Empire ruled all the lands that bordered the sea. The Romans called the Mediterranean *Mare Nostrum* (Our Sea).

From the 1100's to the 1400's, such Mediterranean trading centers as Barcelona, Constantinople, Genoa, and Venice linked Europe and Asia. The ships of these cities brought goods from India and China across the sea to Europe. The Portuguese explorer Vasco da Gama sailed around Africa in 1497, reaching India in 1498. Trading ships then began to use this easier, all-water route to the East. Thus, the sea's importance as a trade route declined until the 1800's.

The opening of the Suez Canal in 1869 made the Mediterranean a part of the shortest water route between Europe and Asia. The sea became one of the world's busiest shipping lanes.

Pollution of the Mediterranean became a serious problem. The major sources of pollution were oil, sewage, agricultural fertilizers and pesticides, and industrial pollutants, including tar, plastic bags, and waste from ships and planes. Most of the pollutants came from coastal settlements or were carried from inland sources by rivers. The pollution posed a threat to sea life. The polluted water also threatened people by spreading typhoid, infectious hepatitis, and other diseases.

In 1976, the United Nations Environment Programme (UNEP) sponsored a treaty called the Convention for the Protection of the Mediterranean Sea Against Pollution. The convention is also known as the Barcelona Convention for the city in Spain where it was signed. All the nations that border the Mediterranean have ratified the

treaty. UNEP conducts programs to develop plans to stop Mediterranean pollution and to study the trends of pollution in the sea. Warren E. Yasso

Medusa, *muh DOO suh,* was one of the three Gorgons, and the only mortal Gorgon (see **Gorgons**). Medusa and her two sisters had writhing snakes for hair, staring eyes, hideous grins, and protruding fangs. They were so ugly that anyone who saw them turned to stone.

Unlike her sisters, Medusa had been beautiful in her youth, and was still proud of her hair. She boasted of her beauty to Athena, who became jealous and changed her into a hideous person.

Perseus killed Medusa by looking into his mirrorlike shield as he cut off her head (see **Perseus**). At that time, Medusa had been made pregnant by the sea god Poseidon. The winged horse Pegasus sprang from her beheaded body, and poisonous snakes arose from the blood that dripped from her head. Athena saved blood from Medusa's body and gave it to Asclepius, the god of healing (see **Asclepius**). The blood from Medusa's left side was a fatal poison, but that from her right side had the power to revive the dead. Justin M. Glenn

Meech Lake accord. See **Quebec** (Recent developments).

Meeker, Ezra (1830-1928), was an American pioneer and author. In 1852, he took a five-month journey by oxcart along the Oregon Trail from Iowa to Portland, Oregon, with his wife and infant son. He returned to Iowa by the same route in 1906, painting inscriptions on landmarks along the way as part of a memorial observance. He made a similar trip by car in 1915. He spent much of his time after the age of 75 promoting the memory of the Oregon Trail. Meeker founded the Oregon Trail Association. His books include *Ox-Team Days on the Oregon Trail* (1922) and *Kate Mulhall* (1926). Meeker was born in Huntsville, Ohio. Dan L. Flores

Meerkat is a small burrowing animal of Africa. It lives from southwestern Angola to South Africa. The meerkat, also called *suricate,* is found in open, dry country where the ground is hard and stony.

Adult meerkats measure about 20 inches (51 centimeters) long, including a tail of about 8 inches (20 centimeters). They weigh about 2 pounds (900 grams). Meerkats have front feet with strong, curved claws for digging, and stocky hind legs. They have broad, rounded heads and sharply pointed noses. Most meerkats are silvery-brown, with dark bands across their backs.

Meerkats live in underground colonies of up to 30 individuals. Their burrows have many tunnels and entrances. Meerkats leave their burrows only during the day. They often stand upright, exposing their chests and bellies to the sun. They also stand upright to search for

© Charles G. Summers, Jr., Tom Stack & Assoc.

Meerkats often stand upright to search for birds that may attack them. These burrowing animals live in southern Africa.

large birds that hunt them. Meerkats eat mostly spiders and insects, including beetles and grasshoppers.

Duane A. Schlitter

Scientific classification. The meerkat belongs to the family Herpestidae. Its scientific name is *Suricata suricatta.*

Meerschaum, *MIHR shuhm,* is a soft, whitish fibrous or flaky clay. Manufacturers use it to make tobacco pipes. Meerschaum is also called *sepiolite.* It is so light that it will float in water. In German, the word *meerschaum* means *sea foam.* The mineral gets its name because it floats and has the look of foam. Large quantities of meerschaum are found in Asia Minor. Lumps of it are found in masses of other types of clay. Meerschaum is a compound of magnesium, silicon, oxygen, and water. It is a water-bearing magnesium silicate.

Many smokers prefer meerschaum tobacco pipes. The bowls of these pipes are white when new. With careful use, the bowl slowly colors a rich brown. Meerschaum pipes break easily. Ray E. Ferrell, Jr.

Megalithic monuments, MEHG *uh LIHTH ihk,* are structures built of large stones by prehistoric people for burial or religious purposes. The word *megalith* means *large stone.* The stones may weigh from 25 to 100 short tons (23 to 91 metric tons) each. Megalithic monuments can be found in various parts of the world. The best-known ones are in western Europe and were built between 4000 and 1500 B.C. Many megalithic structures served as tombs. Some of these tombs had passages. Other tombs, called *dolmens,* consisted of a small, simple chamber. Such tombs have been discovered in many parts of western and southern Europe.

Single, erect stones are called *menhirs.* A monument composed of menhirs arranged in a circle and surrounded by a bank of earth and a ditch is called a *henge.* The most famous henge, Stonehenge, stands near Salisbury, England (see **Stonehenge**). Menhirs were also arranged in parallel rows called *alignments.* Elaborate alignments near Carnac in northwestern France extend over 2 miles (3 kilometers). Bruce Kraig

Megalopolis, *mehg uh LAHP uh lihs,* is a region of two or more metropolitan areas. A metropolitan area consists of a central city that has a population of at least 50,000 and the city's suburbs. Metropolitan areas form a megalopolis if they attract enough people and industry and then expand and begin to grow together.

Megalopolis

This map shows in light red the largest developing *megalopolis* (continuous metropolitan area) in the United States. Built-up areas are shown in dark red.

WORLD BOOK map

The largest United States megalopolis includes the metropolitan areas of Boston, New York City, Philadelphia, Baltimore, and Washington, D.C. It extends about 600 miles (960 kilometers) from southern New Hampshire into northern Virginia and has about 42 million people. Other developing U.S. megalopolises include (1) the area from San Francisco, through Los Angeles, to San Diego; (2) the area from Milwaukee, through Chicago and Cleveland, to Pittsburgh; and (3) the area from Dallas and Fort Worth to Houston.

The French geographer Jean Gottmann introduced the term *megalopolis* in 1961 to describe the urban development in the northeastern United States. The term comes from the Greek words *megalo* and *polis,* meaning *great city.* Megalopolises developing outside the United States include the Tokyo-Yokohama-Osaka area in Japan and the Ruhr Industrial Basin in Germany, the Netherlands, and Belgium. Louis H. Masotti

See also **Metropolitan area**.

Mehmet II, *meh HEHM eht* (1432-1481), was the seventh sultan (ruler) of the Ottoman Empire. He is sometimes called The Conqueror because he conquered Constantinople (now Istanbul), capital of the Byzantine Empire, in 1453. His victory ended that empire, which once ruled much of Africa, Europe, and the Middle East.

Mehmet became sultan in 1444 but was deposed in 1446. He regained power in 1451 and ruled until 1481 as one of the greatest Ottoman sultans. Mehmet extended Ottoman rule in the Balkans, Asia Minor, and the Crimea. He also reorganized the empire's administrative system and rebuilt Istanbul, which had badly deteriorated in the last days of the Byzantine Empire.

Mehmet was born on March 30, 1432, in Adrianople (now in Turkey). He was well educated. He knew several languages and used ideas from other cultures to his empire's advantage. Justin McCarthy

Mehta, *MAY tuh,* **Zubin,** *ZOO bihn* (1936-), is a symphony orchestra conductor. He won fame for forceful interpretations of such large-scale romantic compositions as the works of French composer Hector Berlioz.

Mehta was born on April 29, 1936, in Bombay (now Mumbai), India. He studied conducting in Vienna, Austria, under conductor Hans Swarowsky. Mehta became music director of the Montreal Symphony Orchestra in 1960. In 1962, he took the same position with the Los Angeles Philharmonic, becoming the youngest conductor of a major United States symphony orchestra. He served as director of both orchestras until 1967, when he resigned from the Montreal post. In 1978, Mehta left the Los Angeles Philharmonic to become music director of the New York Philharmonic, a position he held until 1991. He has also served as music director of the Israel Philharmonic Orchestra since 1968. Mehta became music director of the Munich Opera in 1998. Charles H. Webb

Christine Steiner, New York Philharmonic

Zubin Mehta

Meier, Richard (1934-), is an American architect who is famous for his design of geometric buildings. His style draws from the purism of Modernists, especially Le Corbusier and Mies ven der Rohe. It includes simple geometric masses, many of them pure white in color.

Tom Bonner © The J. Paul Getty Trust

Richard Meier's design for the Getty Center in Los Angeles reflects the architect's undecorated geometric style.

Richard Alan Meier was born on Oct. 12, 1934, in Newark, New Jersey. He received a bachelor's degree in architecture from Cornell University. He later worked with Marcel Breuer, a Hungarian-born architect and furniture designer. In 1963, Meier opened his own firm. Meier's first major public building was the Atheneum (1979) in New Harmony, Indiana. It incorporates his mature style of ordered geometric white boxes off-set by a few carefully composed curved elements. Meier also designed the Museum for the Decorative Arts (1985) in Frankfurt, Germany; the Museum of Contemporary Art (1995) in Barcelona, Spain; the Getty Center (1997) in Los Angeles; and federal courthouses in Islip, New York, and Phoenix, Arizona (both 2000). King
1926-1930

Meighen, *MEE uhn,* **Arthur** (1874-1960), served as prime minister of Canada two times during the 1920's. He first took office as prime minister in July 1920, succeeding Sir Robert L. Borden. Meighen served as prime minister until December 1921. He held the office again from June to September in 1926. Meighen led the Conservative Party from 1921 to 1926 and in 1941 and 1942.

Meighen accomplished little as prime minister. But he was noted for his bitter and unsuccessful power struggle with Liberal Party chief W. L. Mackenzie King. Meighen failed to lead his party to a parliamentary majority in the elections of 1921, 1925, and 1926. Each time, King became—or remained—prime minister.

Meighen, a lawyer, had a remarkable memory and a gift for eloquent expression. He especially liked to argue and became the most skilled debater in Parliament. A newspaper paid tribute to Meighen's sharpness with words by calling him "The First Swordsman of Parliament." Meighen became one of Borden's chief aides during World War I (1914-1918). During this period, Meighen either developed or defended almost all the government's most controversial policies.

Some Canadians viewed Meighen as a brilliant, honest, and courageous statesman. But many others regarded him as quarrelsome and unwilling to compromise, and still others disliked his critical comments about King. Meighen himself felt that the public often misunderstood him.

Early life

Arthur Meighen was born on June 16, 1874, on a farm near St. Mary's, Ont. He was the second of the six children of Joseph Meighen and Mary Bell Meighen. His parents placed a high value on education, and Arthur became a bright and eager student. He was a serious youth and made it clear to the family that he preferred to be called Arthur rather than Art. In 1896, he graduated from the University of Toronto with honors in mathematics.

Soon afterward, Meighen became a high-school teacher in Caledonia, Ont. But he did not like teaching and quit after a year. In 1898, Meighen moved to Winnipeg. He began to study law there as a clerk in a law firm. He was admitted to the bar in 1903 and established a law practice in Portage la Prairie, Man.

In June 1904, Meighen married Isabel Cox (1883-1985), a schoolteacher from Birtle, Man. They had two sons, Theodore and Maxwell, and a daughter, Lillian.

Entry into public life

Meighen began his political career in 1908, when he won election to the Canadian House of Commons as a Conservative from Portage la Prairie. He was reelected in 1911. In 1913, Meighen was appointed solicitor general after working out a method to cut off a bitter debate over a naval bill that Prime Minister Borden had introduced in the House of Commons. In 1917, Borden named Meighen secretary of state and minister of mines and, later that year, minister of the interior.

During World War I, Meighen played a key role in the development of several controversial measures. One such bill enabled the government to take possession of some important railroads that had gone into debt. Another established a military draft. These bills made

Meighen unpopular in Quebec, where Montreal business executives disliked the railroad take-over and French-speaking Canadians bitterly opposed the draft.

In October 1917, Borden formed a government almost entirely of English-speaking Conservative and Liberal supporters of the draft. This administration became known as the Union Government. Two months later, Borden led the Unionists to victory in a general election. In 1920, he retired because of poor health. Borden's followers in Parliament chose Meighen to succeed him as their leader and prime minister.

Prime minister

First term. When Meighen took office as prime minister on July 10, 1920, his government faced serious political problems. Many of its supporters in the West and in rural Ontario had begun to favor the new Progressive Party, organized by dissatisfied farmers, who wanted lower tariffs. Meighen also had little support in Quebec.

Meighen's most notable achievement as prime minister occurred at a conference of British Empire prime ministers in London in 1921. The conference had been called to consider renewal of the Anglo-Japanese Alliance of 1902. Meighen knew the United States disliked the treaty, and he believed Canada and the United Kingdom would be served best if it expired. Largely because of Meighen's arguments, the conference postponed a decision on renewal. This move helped lead to the Washington Naval Conference of 1921-1922. At this conference, the United Kingdom, Japan, France, Italy, and the United States reached an agreement on arms limitation (see **Arms control**).

By 1921, the wartime union of Conservatives and Liberals had fallen apart. Many Liberals had returned to their old party. Meighen led the Conservatives in the general election that year. But they suffered the worst defeat of any Canadian governing party up to that time. They won only 50 of the 235 seats in the House of Commons and placed third behind the Liberals and the Progressives. Meighen himself lost his seat from Portage la Prairie. W. L. Mackenzie King, the Liberal Party leader, replaced Meighen as prime minister on Dec. 29, 1921.

Opposition leader. Meighen set out to rebuild the Conservative Party. In 1922, he won election to the House of Commons from Grenville, Ontario, and became leader of the opposition in the House. In the 1925 election, Meighen regained his seat from Portage la Prairie. The Conservatives emerged as the largest group in the House of Commons. But they fell seven seats short of a majority, and King won enough support from the Progressives to remain prime minister.

In 1926, a scandal in the customs department disgraced the King administration. King asked Lord Byng, Canada's governor general, to dissolve Parliament so a new election could be held. But Byng refused to do so, and King resigned. Byng believed that Meighen, as leader of the largest party in the House of Commons, should have a chance to form a government.

Second term. On June 29, 1926, Meighen again became prime minister. But his government soon met defeat in the House of Commons on a motion charging that its ministers were serving illegally. This time Byng dissolved Parliament at Meighen's request. The Liberals won the election that followed, and King succeeded Meighen as prime minister on September 25.

Meighen, who had also lost his seat, resigned as Conservative leader and retired from public service. By the end of 1926, he was an investment banker in Toronto.

Later years

Meighen began a political comeback in 1932, when Prime Minister Richard B. Bennett appointed him to the Canadian Senate. Bennett had succeeded Meighen as leader of the Conservative Party and had led the party to victory in the 1930 general election. Meighen became government leader in the Senate, and then leader of the opposition in the Senate after King led the Liberals back to power in 1935.

In 1941, the Conservative Party again chose Meighen as its leader. But his political career lasted only a short time longer. Meighen sought election to the House of Commons from York South, in Toronto. However, he was defeated in February 1942 by a socialist who called for social welfare policies. World War II (1939-1945) was underway, and Meighen again came out in favor of the draft. In December, Meighen retired from politics a second time. But before retiring, he arranged for Premier John Bracken of Manitoba to be selected as leader of the newly renamed Progressive Conservative Party. Meighen devoted the rest of his life chiefly to business activities. J. L. Granatstein

Meiji, *MAY jee,* **Emperor** (1852-1912), reigned in Japan from 1867 to 1912. *Meiji* means *enlightened rule,* and the period of the emperor's reign was known as the Meiji era. During the Meiji era, Japan began to develop as an international industrial and military power.

The emperor gained the throne as the result of a revolution known as the Meiji Restoration. Nobles, military lords called *daimyo,* and hereditary warriors called *samurai* forced the *shogun* (warrior ruler) out of power. Shoguns had ruled Japan for hundreds of years. The leaders of the revolution and their successors were the real rulers during the Meiji era. In the emperor's name, they carried out many reforms. They organized a modern army and navy, created a system of public education, promoted industrial development, and built modern systems of transportation and communication.

Under Emperor Meiji, Japan began to expand its influence. It won wars against China in 1895 and Russia in 1905. In 1910, Japan made Korea a colony. After forming an alliance with the United Kingdom in 1902, Japan gained international recognition as an equal of the Western powers.

The emperor, whose given name was Mutsuhito, was born on Nov. 3, 1852, in Kyoto. In keeping with the practices of Japan's Shinto religion, he was enshrined as a god after his death. Gary D. Allinson

Mein Kampf is a book by Adolf Hitler. Published in two parts in 1925 and 1926, before Hitler became dictator of Germany, the book became a "bible" for the Nazis. The title is German for *My Struggle.* In the book, Hitler wrote that Germans were superior because of their "racial purity." Therefore, they had the "moral right" to conquer and displace the "lesser" races of Eastern Europe and Russia. He wrote that the Jews were the main threat to "racial purity." The ideas in *Mein Kampf* formed the basis of German policies that helped lead to World

War II (1939-1945) and the systematic murder of millions of Jews and other Europeans. See also Hitler, Adolf (*Mein Kampf*). Donald M. McKale

Meir, Golda, *may EER,* (1898-1978), served as prime minister of Israel from 1969 to 1974. During her political career, she supported large-scale immigration to Israel and major housing and construction programs. Her main problem as prime minister was the territorial conflict between Israel and several Arab nations. Meir followed a firm but open policy toward the Arabs.

Wide World
Golda Meir

In October 1973, war broke out for the fourth time between Israel and the Arabs. Israel suffered heavy early losses, and Meir's government was severely criticized. As a result, she resigned in June 1974, even though she had led the Labor Party to victory in the December 1973 elections.

Golda Meir was born Golda Mabovitz on May 3, 1898, in Kiev, Ukraine. Her family moved to Milwaukee in 1906, and she later taught school there. In 1921, she went to Palestine and joined a collective farm village.

In 1948, part of Palestine became the new nation of Israel. Meir served as Israel's minister of labor from 1949 to 1956 and as minister of foreign affairs from 1956 to 1966. She was secretary-general of the Labor Party from 1966 to 1969. Ellis Rivkin

Meistersinger was one of a group of German poet-musicians who treated literary art as a sort of craft or trade. The name *meistersinger* means *mastersinger.*

The tradition of the meistersingers began in the late Middle Ages when middle-class poets tried to revive the declining art of wandering poet-musicians called *minnesingers* (see Minnesinger). Sometime between the late 1200's and the late 1400's, the meistersingers developed rules for song composition and organized song schools modeled after medieval guilds. Members took examinations for admission and promotion. Competitions were held, and prizes were awarded. Most meistersingers were business people or craftworkers. The meistersingers reached their peak in the early 1500's, though the tradition continued into the 1800's.

In the early period, the *Tabulatur* (rulebook) permitted composition only to prescribed melodies. But by the 1500's, original compositions were required to gain the title of *meister.* Poetic themes were usually instructive stories. Meistersingers did not produce great literature but achieved lasting fame through Richard Wagner's opera *Die Meistersinger.* James F. Poag

Meitner, *MYT nuhr,* Lise, *LEE zuh* (1878-1968), was an Austrian-born physicist who played an essential role in the discovery of *nuclear fission* (the splitting of the nucleus of an atom). From 1934 to 1938, Meitner and German chemists Otto Hahn and Fritz Strassmann worked on the reactions that occur when neutrons bombard uranium nuclei. In December 1938, Hahn and Strassmann discovered that such bombardment produces nuclei of *barium,* a chemical element much lighter than uranium. In January 1939, Meitner and her nephew Otto Frisch gave the first explanation of that discovery. They described how neutron bombardment causes uranium nuclei to split into nuclei of barium and other elements, and they calculated the enormous energy released. The work of Meitner, Hahn, Strassmann, and Frisch led to the development of the atomic bomb and other uses of nuclear energy.

Meitner was born in Vienna on Nov. 7, 1878. She earned a doctorate in physics from the University of Vienna in 1906. In 1907, she began working with Hahn in Berlin. She and Hahn were among the first to isolate the element protactinium in 1917. A pioneer for women in physics, she became the first head of the physics department at the Kaiser-Wilhelm Institute of Chemistry (now the Max Planck Institute of Chemistry) in 1917.

In 1938, Meitner fled Nazi Germany because she was of Jewish descent. She then worked at the Nobel Institute for Physics in Stockholm, Sweden. She was a visiting professor at the Catholic University of America in 1946. In 1966, she shared the Enrico Fermi Award with Hahn and Strassmann. Ruth Lewin Sime

See also Nuclear energy (Artificial fission).

Meitnerium is an artificially produced radioactive element with 109 protons—that is, with an *atomic number* of 109. Scientists have discovered two *isotopes* of meitnerium, forms of the element with the same number of protons but different numbers of neutrons. The *atomic mass numbers* (total numbers of protons and neutrons) of these isotopes are 266 and 268. The more stable isotope has a mass number of 268. This isotope has a *half-life* of 0.070 second—that is, due to radioactive decay, only half the atoms in a sample of isotope 268 would still be atoms of that isotope after 0.070 second.

In 1982 and 1984, scientists at the Heavy Ion Research Center in Darmstadt, West Germany (now part of Germany), made claims for the production of the element. They bombarded bismuth, which has an atomic number of 83, with iron, which has an atomic number of 26. In 1985, scientists at the Joint Institute for Nuclear Research in Dubna, near Moscow, produced results that agreed with the Darmstadt claim. Dubna was then part of the Soviet Union and is now in Russia. Further work at Darmstadt in 1988 also agreed with the earlier claims.

In 1986, the International Union of Pure and Applied Chemistry (IUPAC) and the International Union of Pure and Applied Physics formed a working group to review the histories of the elements with atomic numbers from 101 to 109. In 1993, IUPAC accepted the working group's conclusion that the West Germans had first produced the element in 1982. But disagreements about what to name the element delayed an official naming until 1997.

Meitnerium is named after Austrian-born physicist Lise Meitner, who played an essential role in the discovery of *nuclear fission,* the splitting of the atomic nucleus. Meitnerium's chemical symbol is Mt. Richard L. Hahn

Mekong River, *MAY kahng,* is the longest river on the Indochinese peninsula. The Mekong is about 2,600

miles (4,180 kilometers) long. It flows southeastward from China's Qinghai province and forms part of the boundary between Thailand and Laos. See **Thailand** (map). The river crosses Laos, Cambodia, and Vietnam before it empties into the South China Sea near Ho Chi Minh City. In the region of the lower delta, the Mekong is known as the Sai Gon River. Ships can sail only about 350 miles (563 kilometers) up the Mekong. Farther inland, the river is interrupted by rapids and sand bars.

H. J. McPherson

Melaka, *muh LAK uh,* also spelled *Malacca* (pop. 88,073), is the capital of Melaka, a state of Malaysia. Melaka lies on the southwest coast of the Malay Peninsula, 125 miles (201 kilometers) northwest of Singapore. For the location of Melaka, see **Malaysia** (map).

Melaka lies in an area that produces pepper, rice, and sage. In the 1400's, the city became the most important port in Southeast Asia. The Portuguese captured the city in 1511. The Dutch seized Melaka in 1641, and the British gained control of the city in 1824. Melaka is no longer a major Asian port. David P. Chandler

Melanchthon, *muh LANGK thuhn,* **Philipp** (1497-1560), a German humanist and scholar, was Martin Luther's chief associate in starting and leading the Protestant Reformation. Melanchthon wrote the *Loci Communes (Commonplaces,* 1521), a widely read handbook that set down Lutheran doctrines in a systematic way for easy reference. He was also the chief author of the Augsburg Confession, which became the basic statement of faith of the Lutheran Church.

Melanchthon had a calmer personality than did Luther. He continually tried to find compromise solutions to issues that divided Protestants and Catholics, and Protestants from each other. He declared that many such issues were unimportant for salvation and should not block unity among Christians. But Melanchthon also believed that the Roman Catholic Church had forsaken the true Christian tradition several hundred years after Christ. He especially opposed the power of the popes.

Melanchthon was born near Karlsruhe. Like Luther, he was a professor at the University of Wittenberg. He was a brilliant student of classical literature and of the works of the early church fathers. He has been called the "teacher of Germany" because of his influence on high school and university education in that country.

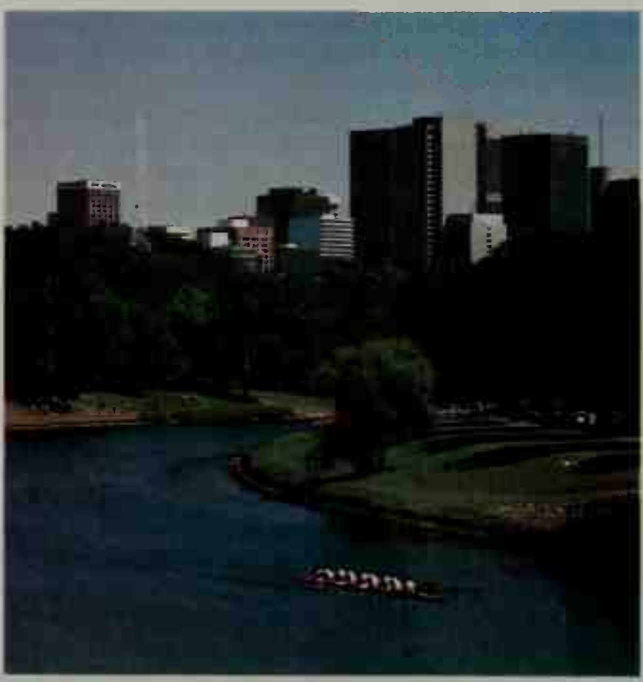
Melba, Nellie (1861-1931), was a famous Australian soprano. Her real name was Helen Porter Mitchell. She adopted her stage name from Melbourne, Australia. Nellie Melba was born in Richmond, which is a suburb of Melbourne.

Nellie Melba first sang in public at the age of 6 in Melbourne. She made her operatic debut in 1887 in Brussels, Belgium, singing the role of Gilda in *Rigoletto.* Melba made her American debut in New York City in 1893. King George V made her a Dame Commander in the Order of the British Empire in 1918, and she became known as Dame Nellie Melba. Martin Bernheimer

Melbourne (pop. 3,138,147) is the second largest city of Australia. Only Sydney has more people. Melbourne, the capital of the state of Victoria, lies on Port Phillip Bay on the southeastern coast (see **Australia** [political map]). Melbourne is a busy seaport, Australia's chief financial city, and Victoria's commercial and industrial center.



The city and its suburbs cover more than 2,400 square miles (6,219 square kilometers). Downtown Melbourne is on the northern shore of Port Phillip Bay. Important buildings include the State Library of Victoria and Parliament House, where the Victoria legislature meets. The Yarra River runs through Melbourne. Several parks surround the city. The Melbourne Cup, a famous horse race, takes place yearly at Flemington Racecourse. The Australian Grand Prix automobile race is also held in Melbourne.

The Melbourne area is the home of La Trobe, Melbourne, and Monash universities, and a number of colleges. The Victorian Arts Centre includes facilities for concerts and plays. The National Gallery of Victoria, an art museum, is part of the Victorian Arts Centre.

The people. Most of Melbourne's residents are of British ancestry. About three-fourths of the people were born in Australia. Many people from Greece, Italy, the United Kingdom, and other European countries, and from Southeast Asia, have settled in Melbourne since World War II ended in 1945.

About 78 percent of Melbourne's families own houses. Large suburbs of single-family houses extend east, north, and west of the city. Melbourne has an extensive public transportation system.

Economy. The value of Melbourne's manufactured products totals about 30 percent of Australia's factory output and about 85 percent of Victoria's. The chief products include automobiles, chemicals, food products, machinery, and textiles. The city's more than 10,000 factories employ about 180,000 workers. Wholesale and retail trading and important financial institutions make Melbourne a major commercial center. It is the hub of Victoria's transportation network. Port Melbourne

D & J. Heaton, Stock, Boston

Melbourne is Australia's second largest city. It is the capital of the state of Victoria. Beautiful parks line the Yarra River.

serves oceangoing vessels. The Melbourne area has an international airport at Tullamarine.

History. Aborigines lived in the Melbourne area before white settlers first arrived. John Batman, an Australian farmer, founded Melbourne in June 1835. Batman represented a group of people from the nearby island of Tasmania who wanted land for sheep farms. He bought 600,000 acres (240,000 hectares) from the Aborigines and paid them with blankets, tomahawks, and other goods. In October 1835, another group of settlers from Tasmania arrived. They were led by John Pascoe Fawkner. A village developed by the Yarra River. The governor of New South Wales later named the village for Viscount Melbourne, the British prime minister.

Melbourne was incorporated as a city in 1847. In 1851, part of New South Wales became a separate colony named Victoria, with Melbourne as its capital. That same year, miners discovered gold in Victoria, and a gold rush began. The city's population jumped from 23,000 in 1851 to 140,000 in 1861. It was Australia's largest city from 1856 until Sydney outgrew it in 1911. Melbourne also served as the capital of Australia from 1901 until 1927, when Canberra replaced it.

World War II (1939-1945) brought new industries and workers to the Melbourne area. Postwar growth was steady, with new industrial development attracting immigrants. The city's population rose dramatically. In the late 1990's, work began on a major urban renewal project known as Federation Square. Peter McLaughlin

Melcher, Frederic Gershom (1879-1963), won the Regina Medal in 1962 for his contributions to children's literature. In 1919, he helped found Children's Book Week. He established the Newbery Medal in 1921 for the outstanding children's book of the year, and the Caldecott Medal in 1937 for the best-illustrated children's book of the year. Born in Malden, Massachusetts, Melcher was coeditor of *Publishers' Weekly* for 40 years. He also served as board chairman of the R. R. Bowker Publishing Company. See also **Caldecott Medal; Literature for children** (Awards). Kathryn Pierson Jennings

Mellon, Andrew William (1855-1937), was an American financier. President Warren G. Harding appointed him United States secretary of the treasury in 1921. Mellon served until 1932 under Presidents Harding, Calvin Coolidge, and Herbert Hoover. While Mellon was in office, the U.S. government reduced by $9 billion its debt from World War I (1914-1918), and Congress cut income tax rates substantially.

Mellon was born in Pittsburgh, Pennsylvania, of wealthy parents. In 1886, he joined his father's bank, Thomas Mellon and Sons, and became a shrewd judge of which new businesses and young business people deserved loans. Mellon served as an officer or director of many financial and industrial corporations. He became especially active in the development of the coal, coke, oil, and aluminum industries. By 1921, he had become one of the wealthiest people in the United States. Mellon served as U.S. ambassador to the United Kingdom in 1932 and 1933. In 1937, he gave his $25-million art collection to the U.S. government. He also donated $15 million for a museum to house the collection. This museum, the National Gallery of Art in Washington, D.C., opened in 1941 (see **National Gallery of Art**).

James S. Olson

Mellon Foundation is an organization that grants funds to institutions in a number of fields. These fields include higher education; cultural affairs and the performing arts; education and research in health and population; and certain areas of conservation and public affairs. The foundation does not make grants to individuals or to strictly local organizations. It ranks as one of the wealthiest foundations in the United States. For assets, see **Foundations** (table).

The foundation was established in 1969 in memory of Andrew W. Mellon, an American financier. Mellon's daughter and son, Ailsa Mellon Bruce and Paul Mellon, formed it by combining the Avalon Foundation and the Old Dominion Foundation. Ailsa had set up Avalon in 1940, and Paul established Old Dominion in 1941. The Mellon Foundation has headquarters in New York City. Its official name is the Andrew W. Mellon Foundation.

Critically reviewed by the Andrew W. Mellon Foundation

Melon is the name of the fruit of several plants that belong to the gourd family. Melon plants have trailing or climbing stems that fasten themselves with tendrils to the objects they climb over. *Tendrils* are modified leaves that look like small coils of wire. The fruits, or melons, are round or somewhat egg-shaped. They measure up to 1 foot (30 centimeters) or more across. The fruits vary from tan and yellow to light or dark green. The flesh may be green, white, yellow, orange, pink, or red.

Gary W. Elmstrom

Scientific classification. Melons belong to the gourd family, Cucurbitaceae.

Melting point is the temperature at which a substance changes from a solid to a liquid. The melting points of different substances vary considerably. For example, tungsten has an extremely high melting point, 3410 °C, but solid hydrogen melts at −259 °C. The melting point of a material depends partly on whether the material is a *pure substance* or a *mixture.* A pure substance is either a pure element, such as iron, or a simple compound, such as water. A mixture consists of two or more substances that are not chemically combined.

A pure substance melts at a definite temperature or within a narrow temperature range. For example, when iron is heated, its temperature rises until the metal reaches its melting point of 1535 °C. The iron remains at that temperature until all the metal has melted.

Mixtures do not melt at a specific temperature. Simple mixtures, such as brass and steel, melt over a range of temperatures. For example, steel, which is a mixture of iron and other elements, has a melting point of 1400 °C to 1500 °C. Thus, the temperature of steel rises 100 °C during the melting process instead of remaining constant. Such complex mixtures as glass and tar do not melt over a specific temperature range. Instead, these substances gradually become softer and more fluid as their temperature increases.

The melting point of most simple mixtures differs from that of any of the pure substances in the mixtures.

Brass, an alloy of copper and zinc, melts over a range of 900 °C to 1000 °C. However, the melting point of copper is 1083.4 °C, and that of zinc is 419.58 °C.

The melting point of a substance is affected by atmospheric pressure. An increase in this pressure raises the melting point of most substances. But an increase in atmospheric pressure lowers the melting point of water and of the few other substances that expand when they freeze. All freezing points specified in this article are based on a pressure of *1 atmosphere* (14.696 pounds per square inch [101.325 kilopascals]), the pressure of the atmosphere at average sea level.

The liquid form of a pure substance freezes at the same temperature at which its solid form melts. Thus, the solid and liquid forms can exist together at the melting point without any temperature change in either. For example, if any amount of ice whose temperature is 0 °C, the melting point of ice, is added to any amount of water whose temperature is also 0 °C, the temperature of the resulting ice water will remain 0 °C. Furthermore, the relative proportions of ice and water will remain the same unless heat is added to the ice water or removed from it. However, if heat is added, the ice will begin to melt. If heat is removed, the water will begin to freeze.

The solid and liquid forms of a mixture can exist together over a range of temperatures. This range is determined by the type and amount of each of the pure substances in the mixture.

Some pure solids do not melt when heated. Instead, they change from a solid to a gas. Such substances as arsenic, dry ice, and iodine go through this process, which is called *sublimation.* John P. Chesick

See also Freezing point.

Melting pot. See United States (Ancestry).

Melville, Herman (1819-1891), ranks among America's major authors. He wrote *Moby-Dick,* one of the great novels in literature, and his reputation rests largely on this book. But many of his other works are literary creations of a high order—blending fact, fiction, adventure, and symbolism. Melville's vast personal experience in faraway places was remarkable even in the footloose and exploring world of the 1800's. Melville brought to his extraordinary adventures a vivid imagination and a philosophical skepticism, as well as a remarkable skill in handling the new American language.

His early life. Melville was born in New York City. The family name was Melvill, and he added the "e" to the name. His father was a merchant from New England. His mother came from an old, socially prominent New York Dutch family. Melville lived his first 11 years in New York City. In 1831, his father died after suffering a financial and mental breakdown, and the family soon moved to Albany, New York.

Inexperienced and now poor, Melville tried a variety of jobs between 1832 and 1841. He was a clerk in his brother's hat store in Albany, worked in his uncle's bank, taught school near Pittsfield, Massachusetts, and, in 1837, sailed to Liverpool, England, as a cabin boy on a merchant ship. He described this trip in his novel *Redburn.* Melville returned to America and signed on as a seaman on the newly built whaling ship *Acushnet* for a trip in the Pacific Ocean. From this trip came the basic experiences recorded in several of his books, and above all, the whaling knowledge he put into *Moby-Dick.*

Herman Melville by A. W. Twitchell. The Berkshire Athenaeum, Pittsfield, Mass.

Herman Melville

Melville sailed from New Bedford, Massachusetts, on Jan. 3, 1841. He stayed on the *Acushnet* for 18 months. After the ship put in at Nuka Hiva in the Marquesas Islands, he and a shipmate deserted. The two men headed inland until they accidentally came to the lovely valley of the Typees, a Polynesian tribe with a reputation as fierce cannibals. But the natives turned out to be gentle, charming hosts. Melville described his experiences with them in *Typee.*

Melville lived in the valley for about a month. He then joined another whaling ship, but he soon deserted it with other sailors in a semimutiny at Tahiti. After a few days in a local jail, Melville and a new friend began roaming the beautiful and unspoiled islands of Tahiti and Moorea. Melville described his life during these wanderings in the novel *Omoo.*

After short service on a third whaling ship, Melville landed at the Sandwich Islands (now Hawaii), where he lived by doing odd jobs. On Aug. 17, 1843, he enlisted as a seaman on the frigate *United States,* flagship of the Navy's Pacific Squadron. He recounted his long voyage around Cape Horn in the novel *White-Jacket.*

Melville arrived in Boston Harbor in October 1844. He was released from the Navy and headed home to Albany, his imagination overflowing with his adventures.

His literary career. Melville wrote about his experiences so attractively that he soon became one of the most popular writers of his time. The books that made his reputation were *Typee* (1846); *Omoo* (1847); *Mardi* (1849), a complex allegorical romance set in the South Seas; *Redburn* (1849); and *White-Jacket* (1850).

Melville then began *Moby-Dick,* another "whaling voyage," as he called it, similar to his successful travel books. He had almost completed the book when he met Nathaniel Hawthorne. Hawthorne inspired him to radically revise the whaling documentary into a novel of both universal significance and literary complexity.

Moby-Dick, or The Whale (1851), on one level, is the story of the hunt for Moby Dick, a fierce white whale supposedly known to sailors of Melville's time. Captain Ahab is the captain of the whaling ship *Pequod.* He has lost a leg in an earlier battle with Moby Dick, and is determined to catch the whale. The novel brilliantly describes the dangerous and often violent life on a whaling ship, and contains information on the whaling industry and a discussion of the nature of whales. On another level *Moby-Dick* is a deeply symbolic story. The whale symbolizes the mysterious and complex force of the universe, and Captain Ahab represents the heroic struggle against the limiting and crippling constrictions that confront an intelligent person.

Melville's popularity began to decline with the publication of his masterpiece. The novel, either ignored or misunderstood by critics and readers, damaged Melville's reputation as a writer. When Melville followed *Moby-Dick* with the pessimistic and tragic novel *Pierre*

(1853), his readers began to desert him, calling him either eccentric or mad. The public was ready to accept unusual and exciting adventures, but they did not want ironic, frightening exposures of the terrible double meanings in life.

Melville turned to writing short stories. Two of them, "Benito Cereno" and "Bartleby the Scrivener," rank as classics. But the haunting and disturbing question of the meaning of life that hovered over the stories also displeased the public. In 1855, Melville published *Israel Potter,* a novel set during the Revolutionary War in America. After *The Confidence-Man* (1856), a bitter satire on humanity, Melville gave up writing.

His later life. To make a living, Melville worked as deputy inspector of customs in the Port of New York from 1866 to 1885. For private pleasure he wrote poetry, which he published at his own and his uncle's expense. He toured the Holy Land in 1856 and 1857. The trip resulted in a narrative poem, *Clarel* (1876). The poem presents a powerful picture of a man's struggle to find his faith in a skeptical, materialistic world.

Melville began writing prose again after his retirement. At his death, he left the manuscript of *Billy Budd, Sailor.* This short novel, first published in 1924 and considered Melville's finest book after *Moby-Dick,* is a symbolic story about the clash between innocence and evil, and between social forms and individual liberty.

The 1920's marked the start of a Melville revival among critics and readers. By the 1940's, Americans at last recognized his genius. His reputation has since spread throughout the world. John Clendenning

Melville Island is one of a group of Canadian islands in the Arctic Ocean, north of Canada's mainland. It lies between Prince Patrick and Bathurst islands, and is one of the Parry Islands. See **Canada** (terrain map). The island covers about 16,300 square miles (42,220 square kilometers). It stretches nearly 200 miles (320 kilometers) from east to west, and about 130 miles (209 kilometers) at its widest north to south point. Frozen seas surround it most of the year. The island is uninhabited.
